Singapore tramways are in the hands of the same contractors, and are making considerable progress. The power-house contains eight Lancashire boilers, with the usual accessories, including two fuel economisers and four feed pumps, three engines, two of Yates and Thom's horizontal cross-compound condensing type, coupled direct to two of Dick-Kerr's standard 500-kw. 100 r.p.m. 500-volt compound generators. For lighting purposes a 200-kw. plant has been installed, including one direct-current generator of 150 kw. capacity coupled direct to a Willans engine, also a 50-kw. motor-driven generator working off a circuit of 550 volts. A suitable switchboard has been supplied and erected by the contractors. The overhead work has been carried out on the span-wire system. The total length of single track is 27 miles, and is laid to a gauge of 1m., and the form of construction consists of laying girder type rails weighing 95lb. per yard upon a continuous beam of concrete. The rolling-stock consists of 50 cars, 20 single-deck single-truck combination type, with a seating capacity of 32 persons, 16 inside and 16 outside, and 30 open cross-bench type to seat 40 persons. They are mounted on Brill 21E trucks and equipped with 25B motors and DB1 form "C" controller. In addition, there are 33 goods vans mounted on Brill 21G trucks, each with a double-motor equipment, the whole of the rolling-stock being built by the Electric Railway and Tramway Carriage Works, Preston.

Lastly, that most successful tramway owned by the Calcutta Tramways Company is carrying out considerable extensions, and this work has been entrusted to the original contractors—Dick, Kerr, and Co., Limited. This includes an additional 10 open-type motorcars, in all respects the same as those supplied before—*i.e.*, single-deck open-type cars, mounted on Brill 21E trucks, and equipped with two 25A motors, each with a DE1 form C controller. The main station plant is being increased by one of Dick-Kerr's standard three-phase alternators, 500 kw., 25 cycles, 6,000 volts, 94 revolutions per minute, direct coupled to a Yates and Thom horizontal cross-compound engine, and a switchboard built by Dick, Kerr, and Co. There are two sub-stations being erected, in which will be placed a 300-kw. rotary converter, with the necessary transformers and switchgear.

SINGLE-PHASE MOTORS—V. A. FYNN'S PATENT.

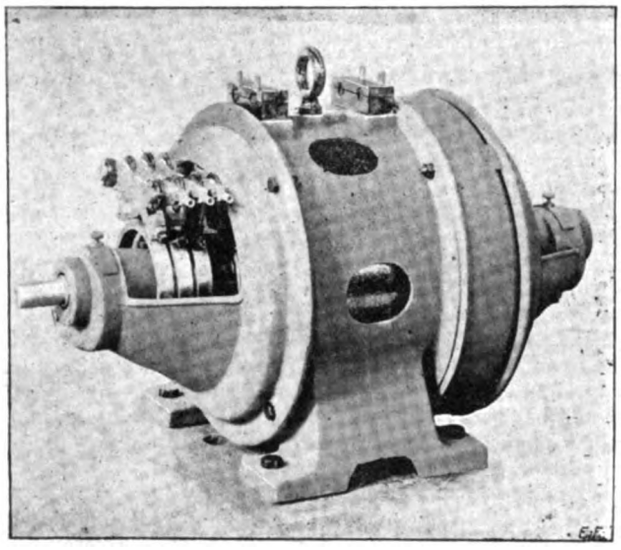
The following notes gives a brief description of the latest type of repulsion-induction motors which has been placed on the market. They are supplied by Messrs. Witting, Eborall, and Co., who have sent us the following particulars:

The motors are manufactured under Mr. V. A. Fynn's patents; they are of the commutator type specially designed to give a large starting torque with a comparatively small current consumption, and are specially suitable for lift and crane work. In these motors the rotor has two interconnected windings, the ends of the one being connected to slip-rings, and the ends of the coils of the other to a commutator. The winding of the two-pole machine is given in the accompanying diagram. The stator has simply a standard three-phase winding.

In the larger sizes of motors the brushes on the commutator are connected through a variable resistance which is gradually cut out as the motor starts, and is short-circuited in the running position. In the smaller motors the brushes are permanently short-circuited. The brushes are fixed once for all, and no adjustment for these is necessary. The slip-ring brushes are connected to a resistance exactly similar to the starter of an ordinary three-phase motor. The construction of the motor is such that at starting it operates as a repulsion motor, and at full speed as a synchronous motor; at intermediate speeds the motor works partly as an induction and partly as a repulsion motor. Sparkless running of the brushes is guaranteed

Digitized by Google

at any speed. A set of curves are here given to show the performance of a 220-volt 50-cycle 4-b.h.p. motor.



Single-Phase Commutator Motor (Fynn's Patent)

With regard to the starting performance generally, the makers guarantee that when starting with a torque equal to that at full load, the starting current will not exceed three-quarters of the full-load current; or when starting

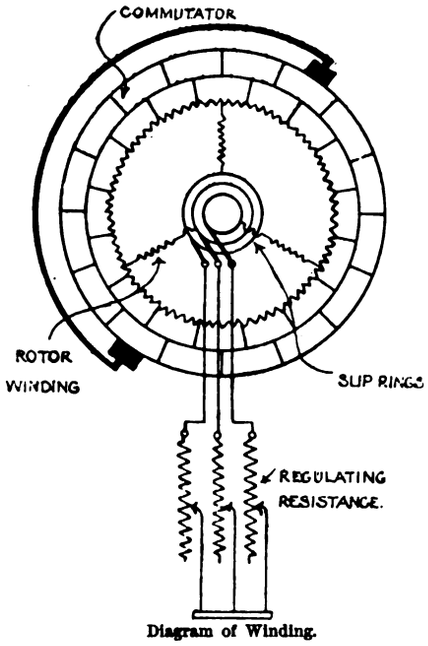


Diagram of Winding.

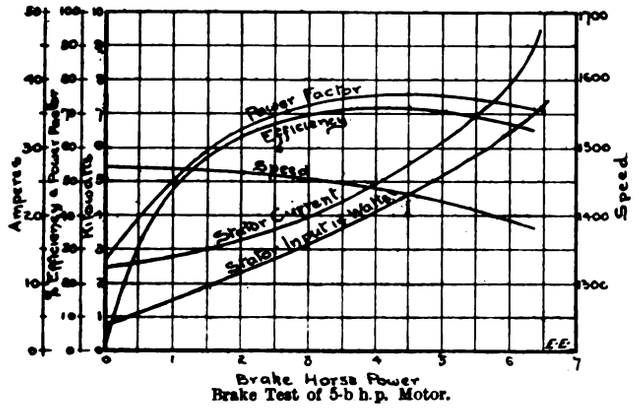
with a torque equal to twice that at full load, the starting current will not exceed 1½ times the full-load current, it being assumed that the pressure at the terminals on the stator remains constant. Those who have had experience



Brake Test of 5-b.h.p. Motor.

with single-phase motors will realise the excellence of this starting performance.

As stated above, the motors are specially suitable for lifts and hoists, but they can be equally well used in other classes of work; however, where a large starting torque is not specially required, the standard induction motors are usually preferable on account of their lower price, and of the absence of the commutator.

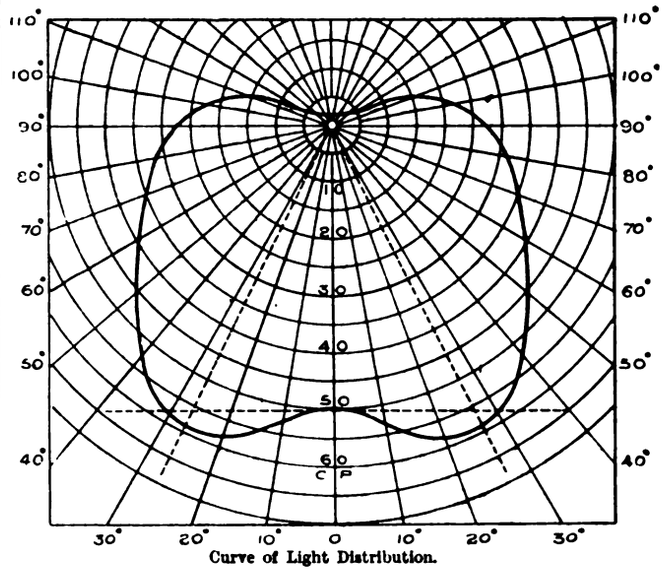
TRADE NOTICES AND NOVELTIES.

The B.T.H. Meridian Lamp.

A lamp to fill the existing gap between the ordinary incandescent lamp and arc lamp should be as simple as the former, and should have an efficiency approaching at least that of the latter. These requirements are met, it is claimed, by the

B.T.-H. Meridian Lamp.

B.T.H. Meridian lamp. This, according to a description for which we are indebted to the British Thomson-Houston Company, Limited, Rugby, is a new type of incandescent filament lamp, having a large spherical globe and translucent prismatic reflector. The lamp is specially designed to give an almost



Curve of Light Distribution.

perfect distribution of light in the lower hemisphere with a comparatively small expenditure of energy. The bulb is obscured, and when the lamp is burning it has the appearance of a globe of soft, brilliant white light. The excellent light distribution in all useful directions is shown in the accompany-

Digitized by Google

ing diagram. The maximum candle-power is about 58 at an angle of 30deg. from the vertical, and an average candle-power of about 55 is well maintained over an angle of 60deg. The dotted triangle shows that this peculiar distribution produces a practically uniform illumination of great intensity over a circular field, whose diameter approximates its distance below the lamp. The lamp has been specially designed to give this distribution of light, which makes possible efficient illumination from a source of light above the line of vision—a method of lighting involving the least strain on the eyes. It is, therefore, particularly adapted for ceiling suspension, and is not intended to be used on wall brackets or side fixtures. For drawing offices, libraries, and similar places, the globes should hang about 4ft. or 5ft. above the desks or tables, and for general illumination they should be about 8ft. to 12ft. above the floor, depending upon the reflecting power of the walls and ceiling. The Meridian lamp is specially adapted for show-window, shop, and office lighting, and in general for all kinds of illumination where a downward distribution is desirable. To obtain the best lighting effect in art galleries the source of light should be above and behind the observer. Meridian lamps, either singly or in groups, exactly meet the requirements.

CHESTER TRAMWAYS ACCOUNTS.

The statement of accounts for the period from April 6, 1903, to March 25, 1904, shows a total expenditure on capital account of upwards of £66,000. Appended are abstracts of the revenue account and general balance-sheet.

REVENUE ACCOUNT.

PERSONAL.

Mr. M. D. Keith Murray, D.L., has been appointed town clerk of Thurso in room of the late Mr. A. Manson.

At the Rochdale electricity works last week Mr. Fred. H. Rudd, station superintendent, was, on the occasion of his marriage to Miss Annie Crompton, of Bolton, presented with a beautiful barometer mounted in an oak frame suitably inscribed, a case of silver serviette rings, a case of pipes, etc.

APPOINTMENTS VACANT.

Resident Electrical Engineer, St. Marylebone Borough Council. Salary, £600 per annum. Applications by Sept. 5. See advertisement.

Engineer-in-Charge, Southport Corporation. Commencing salary, £2. 5s. per week. Applications by Aug. 22. See advertisement.

Engineer with good knowledge of mechanical and electrical engineering. Salary, £400 to £600. Apply, G M 93, Messrs. Deacon's, 154, Leadenhall-street, London. See advertisement.

Lecturer in Electrical Engineering in the University of Sydney, N.S.W. Salary, £500 per annum. Applications by Sept. 10.

Jointer, for Weymouth and Melcombe Electricity Committee, salary £2 per week; also Fitter-Driver, salary 35s. per week; and a Switchboard Attendant, salary 25s. per week.

BRITISH STANDARDS FOR ELECTRICAL MACHINERY.

The following is the interim report issued by the Engineering Standards Committee dealing with electrical machinery:

In publishing the interim report of the Sub-Committee on Generators, Motors, and Transformers, it will be as well to draw attention to some of the important points which have arisen in carrying out the work entrusted to the sub-committee by the Electrical Plant Committee. The Sub-Committee on Generators, Motors, and Transformers was appointed at a meeting of the Electrical Plant Committee on Dec. 18, 1902, and confirmed by the main committee on Feb. 13, 1903. This interim report was approved by the main committee at their meeting on July 26, 1904. At the earlier meetings it was decided that no attempt should be made to prescribe standard dimensions or shapes which might hamper future development in design, but to confine the recommendations of the sub-committee to such points as would ensure uniformity in nomenclature, outputs, and test conditions. The recommendations which the committee have arrived at with reference to standard pressures, frequencies, outputs, and speeds were prepared after the views of both users and manufacturers had been very carefully considered. Before standard test conditions can be laid down, the safe limit of temperature at which electrical machinery can be allowed to work for lengthened periods of time has, of course, to be determined. A sub-committee under the chairmanship of Dr. Glazebrook was, therefore, formed to experimentally investigate this matter at the National Physical Laboratory, supplemented by tests at the works of those manufacturers who were willing to assist.

The points to be investigated were the following: (1) the maximum temperature to which the insulating materials at present used in the manufacture of electrical apparatus could be exposed for lengthened periods of time without electrical or mechanical deterioration; (2) the permissible rise in temperature deduced from these experiments; (3) the relation between the mean temperature of any coil obtained by measurement of rise in resistance and the maximum temperature at the hottest portion of the same coil.

In addition to these experiments, some of the coils which were tested singly at the National Physical Laboratory were subjected to a second series of tests when mounted on the machines for which they were intended, at the makers' works. The reports of this experimental work are likely to be of very great interest and value to the electrical industry at large, and the committee hope to publish them in full at an early date. It will be of interest to designers to note that the experimental work has made sufficient progress to indicate with considerable certainty that the temperature limits ultimately to be recommended by this sub-committee are likely to be more liberal than those laid down by either the American or German Electrical Standardisation Committees. The experiments have also demonstrated that the temperature of the hottest part of the coils, taken by thermo junction, is no more than 25deg. C. in excess of the mean temperature of the coil, taken by rise in resistance.

The question of settling the standard electrical pressures did not meet with as much difficulty as was anticipated. Care was taken to select those standard pressures which, with the allowable variation of 10 per cent. on either side, would enable nearly all the pressures at present existing to be served by the proposed standard machines. These standard pressures have now been fixed, and it is hoped that *in all future work* they will be universally adopted by engineers who are advising power companies, corporations, supply companies, and others engaged in the distribution of electrical energy, so that in these cases the permissible variations will gradually cease to be necessary.

The standard frequencies proved to be a debatable matter, and after several circular letters had been addressed to and replies received from both users and makers, it was deemed advisable to convene a conference, so that the matter might be thoroughly discussed. This conference was held early in January, and the advisability of adopting two or three

Digitized by Google

standard frequencies was fully considered, especially from the point of view of the future developments in power schemes. Strong evidence was brought forward in favour of standardising one frequency only, and the sub-committee after due consideration decided to recommend 50 periods per second as the standard frequency, placing 25 periods per second in a secondary category.

The question of recommending standard lists of motor speeds, which appeared so desirable from the users' point of view, was found to be an extremely difficult one. The sub-committee felt that they could not materially assist manufacturers in reducing the number of patterns to be kept in stock, if a greater number of speeds were retained than those recommended in the standard lists. Happily, one list of speeds—namely, that for prime movers—was practically fixed for the committee by the conditions of the frequency and the number of the poles in the alternators, so that the committee decided to put forward this one list of speeds for the whole of the direct-coupled machinery of both classes.

The Sub-Committee on Generators, Motors, and Transformers are indebted to the Transformer Sub-Committee for the recommendations with reference to alternating-current generators. They have still under consideration the very important subjects of the standardisation of transformers, test conditions, and permissible variations from the adopted standards, and the complete report cannot be published until such time as these investigations are concluded. The committee, however, feel that the interests of the electrical profession will best be served by the early publication of a portion of the information which will ultimately be embodied in the report when complete.

(Signed) R. E. B. CROMPTON,
Chairman of Sub-Committee on Generators, Motors, and Transformers

We have previously published the names of the experts forming this sub-committee, on which the Admiralty, the War Office, the Crown Agents for the Colonies, the National Physical Laboratory, and the Electrical Engineering Plant Manufacturers' Association were specially represented.

PRESSURES AND FREQUENCIES.

The following are the resolutions with reference to British standard pressures and frequencies:

1. Resolved that the standard low pressures for direct and alternating current work, measured at the terminals of the consumer, be

   110, 220, 440, 500 volts.

   Though not included in the above standard pressures, 380 volts shall be considered as the recognised pressure to be maintained between the principal conductors in a three-phase system with neutral wire, the pressure then being 220 volts between the three conductors and the neutral.

2. Resolved that the standard high pressures for alternating-current work, measured at the terminals of the generator, be

   2,200, 3,300, 6,600, 11,000 volts.

3. Resolved that the standard primary pressures for alternating-current transformer work, measured at the primary terminals of the transformer, be

   2,000, 3,000, 6,000, 10,000 volts.

4. Resolved that the standard secondary pressures for alternating-current transformer work, measured at the secondary terminals of the transformer, be

   115, 230, 460, 525 volts at no load.

5. Resolved that the standard direct-current pressure for tramway work, measured at the terminals of the motor, be

   500 volts.

6. Resolved that the standard frequency for alternating-current work be

   50 periods per second.

But where the circumstances of the case demand a lower frequency, a standard of 25 periods per second shall be adopted. N.B.—The above standard pressures are subject to a permissible variation of 10 per cent. on either side, as explained in the introduction.

RATING OF GENERATORS AND MOTORS.

(Except for Traction Motors.)

1. Two ratings shall be recognised by the British Engineering Standards Committee: (*a*) continuous working; (*b*) intermittent working. (*a*) The output of generators and motors for continuous working shall be defined as the output at which they can work continuously for *six hours* and conform to the prescribed tests; (*b*) the output of motors for intermittent working shall be defined as the output at which they can work for one hour and conform to the prescribed tests. N.B.—The duration of test for machines above 250 kw. is still under consideration.

2. Every generator and motor shall carry in a conspicuous position a name plate, giving the output and other particulars enumerated below. In the absence of any statement to the contrary, the output given shall always be understood to mean the output for continuous working under Rating (*a*). Name plates for machines under Class (*b*) shall bear the word "intermittent."

3. The output and full load speed marked on the name plate shall be those taken when the machine is at its normal working temperature, as determined at the close of the test run referred to above.

4. All generators shall have their outputs stated in kilowatts. All motors shall have their outputs stated in brake horse-power.

5. The following information shall be given on the name plates:

Generators.

Direct current	Kw.	Volts.	Amps.	R.P.M.
Alternating current.	Kw.	Volts.	Amps.	Power factor.
	Full load. / Excitation.	Volts. / Amps.	Frequency.	R.P.M.

Motors.

D.C. (continuous working)	B.H.P.	Volts.	R.P.M.
D.C. (intermittent working)	B.H.P. (Intermittent).	Volts.	R.P.M.
A.C. (continuous working)	B.H.P.	Volts. Frequency.	R.P.M. Power factor.
A.C. (intermittent working)	B.H.P. (Intermittent).	Volts. Frequency.	R.P.M. Power factor.

The above applies to combined machines, such as motor generators, boosters, rotary converters, which shall have name plates giving information applying both to input and output.

DIRECT-CURRENT GENERATORS.

6. The list numbers represent the kilowatts which the machine can work at when continuously as a generator. List numbers and speeds of direct-current generators (up to 100 kw.):

List. No.	Standard motor carcase.	Revs per min.	List. No.	Standard motor carcase.	Revs. per min.
6	7½	1,075	32	40	750
8	10	1 000	40	50	675
12	15	900	60	75	625
16	20	850	90	100	575
24	30	800	100	—	500

British standard generators of 100 kw. and above, whether for direct or alternating current work, shall conform to the following list of sizes and speeds recommended for generators to be directly coupled to steam or gas engines:

Kw.	Revolutions per minute—Slow.	Medium.	High.
100	*	250	500
150	*	250	428
200	*	250	375
250	*	250	375
300	94	214	375
400	94	214	375
500	83	214	300
750	83	188	250
1,000	83	188	250

N.B.—The "slow" speeds in the above table are tentative.

ALTERNATING-CURRENT GENERATORS.

7. British standard alternators of any type, in addition to the requirements laid down in previous clauses, in so far as the latter apply, shall conform to the following regulations: (*a*) They shall give an E.M.F. curve which, under all working conditions, shall be as nearly as possible

Digitized by Google

a sine wave. (*b*) For exciting the field magnets the standard pressures shall be:

65, 110, or 220 volts.

(*c*) The term "alternator" shall not include an "exciter." The latter, when necessary, shall be separately specified and subject to the regulations for standard direct-current generators. (*d*) The regulation of an alternator shall be defined as the difference between the rated full-load pressure and the no-load pressure with the same speed and excitation. This difference expressed as a percentage of the rated full-load pressure shall be termed the percentage "pressure rise" of the alternator. (*e*) They shall not have a greater percentage pressure rise than 6 per cent. on a non-inductive load and 20 per cent. on an inductive load, the latter being here considered as one having a power factor of 0·8. This pressure rise may be tested on a non-inductive or inductive load according to the requirements of the specification. The figures in (B) and (D) shall not apply to compounded alternators.

MOTORS.

8. All motors for the purposes of tests shall be rated under the following classes: (1) open; (2) protected; (3) ventilated; (4) totally enclosed. (1) and (4) require no definition. (2) A *protected* motor is defined as a motor in which the armature, field coils, and other live parts are protected mechanically from accidental or careless contact, so as not to materially interfere with ventilation. (3) A *ventilated* motor is defined as a motor in which, while ventilation is provided for, access to the armature, field coils, and other live parts is only to be obtained by opening a door in, or removing a portion of, the enclosing case. N.B.—An alternating-current motor (Class 3), in which the slip-rings are outside the protection, shall be considered as coming under Class (2).

LISTS OF MOTORS.

9. The list numbers represents the brake horse-power which the machine can work at when running continuously as a motor, at the standard pressure of 220 volts, up to and including two, (2) brake horse-power, and above that size at the standard pressure of 440 volts.

10. The following are the list numbers of British standard sizes of motors: list numbers (direct-current), ¼, ½, 1, 2, 3, 5, 7½, 10, 15, 20, 30, 40, 50, 75, 100; list numbers (single-phase), 50 ⁓, 1, 2, 3, 5, 7½, 7½A, 10, 10A, 15, 20. 25; list numbers (two and three phase), 50 ⁓, 1, 2, 3, 5, 7½, 7½A, 10, 10A, 15, 20, 25, 30, 40, 50, 50A, 75, 100.

11. List numbers and speeds of motors (up to brake horse-power).

Direct-Current Motors.

List No.	R.P.M. at full load.	List No.	R.P.M. at full load.	List No.	R.P.M. at full load.
¼	1,600	5	1,000	30	750
½	1,400	7½	1,000	40	700
1	1,400	10	900	50	650
2	1,100	15	850	75	600
3	1,100	20	800	100	550

Alternating-Current Induction Motors.

Single-phase, 50 ⁓.

List No.	R.P.M. at no load.	List No.	R.P.M. at no load.	List No.	R.P.M. at no load.
1	1,500	7½	1,500	15	1,000
2	1,500	7½A	1,000	20	1,000
3	1,500	10	1,500	25	750
5	1,500	10A	1,000		

Two and three phase, 50 ⁓.

List No.	R.P.M. at no load.	List No.	R.P.M. at no load.	List No.	R.P.M. at no load.
1	1,500	10	1,500	40	750
2	1,500	10A	1,000	50	750
3	1,500	15	1,000	50A	600
5	1,500	20	1,000	75	600
7½	1,500	25	750	100	500
7½A	1,000	30	750		

The figures referring to alternating-current motors give the no-load or synchronous speeds; allowance should, therefore, be made for a reduction in speed at full load of from about 7½ per cent. in the smallest motors to 2½ per cent. in the largest motors.

LEGAL INTELLIGENCE.

MANCHESTER TRAMWAYS PURCHASE.

In the King's Bench Division on Monday Mr. Justice Bigham gave judgment in the special case arising out of the arbitration proceedings connected with the acquisition by the Manchester Corporation of the Manchester Carriage and Tramways Company's undertaking. A question in the case was whether the Corporation were bound to take the depôt at Ashton-under-Lyne, and another point was whether the Carriage Company had a proper title to the depôt.

Mr. Moulton, K.C., for the company, contended that the depôt was the company's property, and not that of the Corporation of Ashton-under-Lyne.

His Lordship said he thought the Corporation must take the Ashton depôt and its contents, they being suitable for the undertaking which had been acquired. Of course, if the company were not in a position to make out their title to the property in question, they would not get the money. He further thought that the value of the undertaking included not only the cost of obtaining parliamentary powers to construct the tramways, but also the cost of the powers to maintain and work it, this being properly part of the cost of construction. But the cost of the company's opposition to private Bills in Parliament which threatened to interfere with the working of the undertaking, ascertained by the arbitrator to be £120, ought not, he thought, to be paid by the Corporation to the company, as it could not be regarded as part of the cost of construction. Judgment must be entered for the company for £13,970, £8,750, and £3,107—the Corporation to pay the company's costs of the proceedings before his lordship.

THE EMPLOYERS' LIABILITY ACT.

In the City of London Court on Tuesday, before his Honour Judge Lumley Smith and a special jury, Charles Howard, of 39, Holmby-street, Albany-road, Camberwell, S.E., claimed £200 from the Electrical Engineering and Maintenance Company, Limited, 5, Eastcheap, for injuries sustained while in their employ. Mr. O'Connor was counsel for plaintiff and Mr. Shakespear for defendant. The action was brought under the Act of 1880. In May last wires were being put up at Snaresbrook, in Essex, and plaintiff alleged that there was negligence on the part of the defendant company in not providing proper ladders, and on the part of their foreman in not seeing that a ladder which was borrowed from Holly Lodge was in good condition. It was a telescopic ladder, and when plaintiff went to raise it with the help of another man named Robinson, the top part came down and broke his arm and caused other injuries to his hand. This was because the locks did not act. Defendants' foreman said Howard had no authority to use the particular ladder, and he could have got one from the asylum, where they had borrowed them from before. Witnesses were called on both sides, and in the end the jury found for plaintiff for £35.

PURLOINING "ENERGY."

At Maidstone Police Court last week Mary Sims was charged with stealing electric current. Prisoner pleaded not guilty.

Mr. Herbert Monckton, who prosecuted on behalf of the Town Council, stated that the house in which the prisoner lived had been wired by the owner, but there was no connection. Suspicion was aroused by the fact that the electric light was seen burning there at night. On examination of the premises it was found that the seal of the wire had been broken and a connection made.

Mr. Hoadley, chief engineer of the electricity department, stated that 82, Boxley-road was wired. He examined the wiring on Friday, and found a temporary connection had been made between the house wiring and the main cut-outs of the Corporation. The cut-outs were unsealed, fuses had been inserted, and the supply was connected throughout the house. He tried several of the lights, and proved that the whole of the wiring was on. No meter was attached. He estimated the amount of electricity consumed at 7s. to 10s. No notice that the light was being used had been received at the electricity works.

Other evidence having been tendered on behalf of the Council, the prisoner made a statement to the effect that the connection was made when she took the house seven weeks ago.

The Bench imposed a fine of 40s., or one month's imprisonment.

COMPANIES' MEETINGS AND REPORTS

CENTRAL LONDON RAILWAY.

The eighteenth ordinary general meeting of this Company was held at the Holborn Restaurant on the 3rd inst., under the chairmanship of Sir Henry Oakley. Particulars of the report were given in our last week's issue.

The **Chairman**, in moving the adoption of the report, said the half-year had been very uneventful. Happily, they had had no serious trouble, hardly a mischance, and the business had gone on with undeviating regularity, and with satisfactory result in the way of profit. The sum of £5,800 had been spent on equipping and strengthening the line, and the new motorcars had cost £7,200, that being almost the completion of the order for the 68 of these cars. They did not anticipate any large capital expenditure of any description, and the completion of the few things they had in hand would be met by £20,000 or £30,000, and that would leave them with £200,000 or £300,000 unspent and practically unraised. They were beginning

Digitized by Google

to see the end of the expenditure unless the line was extended, and they had a substantial sum in hand to meet any emergency. It was considered desirable to keep a substantial balance available, as the Royal Commission on London Traffic had not yet reported, and until the Board knew whether the views or recommendations or suggestions in that report would involve expenditure on the part of the Company, it was thought well to keep in hand as much as possible, so that they might be able to deal efficiently with any recommendation which might be made.

Lord Rathmore seconded the motion.

In reply to a question, the **Chairman** said they carried anybody—peer or peasant—for the double journey at single fare up to 7.30 in the morning—it was a sort of reward for getting up early. They did not believe they made a loss on the workmen's fares, but it was very difficult to separate the two classes of fares.

The motion was carried unanimously, and the dividend at the rate of 4 per cent. per annum on the undivided ordinary and preferred ordinary stock was duly carried.

CROMPTON AND CO.

The sixteenth annual general meeting of the above Company was held on Tuesday at Salisbury House, Mr. J. Trotter (chairman of the Company) presiding.

In moving the adoption of the report (particulars of which we published last week), the **Chairman** stated that the results of the year's working had been disappointing. The results at the end of the first half-year did not justify them in recommending any dividend, and at the end of the year it was found that they had merely enough to admit of the payment of 2½ per cent. In the previous year's report the directors indicated that they were hopeful of the bad times having been passed, and that better times were in store. Their reasons for believing that they were likely to do better during the past year were founded on the fact that they had taken steps to obtain the very best technical advice, both at home and abroad, and had for a long time been overhauling their designs, with a view to cheapening and improving the output of their machines. Every step they had taken to cheapen prices, however, had been nullified by a steady drop in the market value of the regular goods made by the electric manufacturers during the year, which, he regretted to say, steadily continued. They had, however, endeavoured as far as possible to put their house in order. The Chairman then alluded in more optimistic terms to the Electric Supply Corporation, which they had launched, and which was preparing to execute a number of large orders. In conclusion, he referred to the special department that had been established for watching over the sales of the Company. That department had, he considered, already justified its existence, and he predicted that the good work it accomplished in bringing the Company into closer contact with London buyers would be of material benefit in the conduct of the business.

The report was adopted without discussion.

CONSOLIDATED ELECTRICAL.

The second ordinary general meeting of this Company was held on Tuesday at River Plate House, London, under the chairmanship of Mr. Herbert Allen.

The **Chairman**, in moving the adoption of the report (particulars of which we published last week), stated that he could not say anything definite about the future, as at present the business was so poor, and they experienced great difficulty in obtaining orders. Their factory at Canonbury was now in a thoroughly efficient condition, and if it could be made to pay it would be continued; if not, the factory would have to stop. They could not continue their manufacturing branch unless there was a revival in trade.

The report was adopted.

GREAT NORTHERN AND CITY RAILWAY.

The report of this Company to June 30 last states that the receipts for the 19 weeks and five days during which the railway had been opened, up to and including June 30, amounted to £19,354. The number of passengers carried during the above period, excluding season-ticket holders, was 2,711,152. The number of season tickets in use at June 30, 1904, was 758. The working of the railway has been in every way satisfactory, but the traffic receipts are, so far, disappointing, owing almost entirely to the fact that the negotiations with the Great Northern Railway for interchange of through booking facilities have not as yet been completed, and the returns, therefore, show practically no traffic, either in ordinary or season tickets, to or from Great Northern suburban stations. The receipts from local traffic are steadily increasing, and when the arrangements with the Great Northern Railway Company are completed, which it is hoped will be very shortly, the revenue will certainly show a more satisfactory result. The station at Highbury was not opened to the public until June 28 last. As was anticipated, it has already been productive of a considerable increase of traffic, although the lifts are not yet working. While the line is carrying a purely local traffic, it has already attained to a number of passengers, allowing for a complete half-year, larger than that carried by the City and South London Railway, over an equal length of line, at the end of nine years' working. Although the successful development of the traffic may take somewhat longer than was anticipated, the contractors are sanguine that the ultimate results of the railway will fully justify its construction, and in this view the Board concur. The agreement for working the railway by the contractors, for three years from its opening, provides that S. Pearson and Son, Limited, shall retain, in respect of such working, 65 per cent. of the gross receipts from all sources, and that the remaining 35 per cent. shall belong and be paid over to the Company. The contractors have guaranteed, while they so work the railway, a minimum interest of 4 per cent. per annum on the "A" shares if the net receipts paid over to the Company be insufficient; and also a minimum interest of 3 per cent. per annum on certain "B" shares. Warrants for interest will be posted on Aug. 15 to the proprietors entitled to the benefit of the said guarantee.

GREAT NORTHERN, PICCADILLY, AND BROMPTON RAILWAY.

The half-yearly general meeting was held at Hamilton House, Victoria-embankment, Sir Henry Fowler, M.P., presiding.

The report stated that the capital expenditure for the six months ended June 30 last amounted to £717,190, and that the estimate for the current half-year was £900,000. The rent due from the Underground Electric Railways Company of London, Limited, under the terms of the agreement for lease, dated Jan. 13, 1903, up to the close of the period under review, permitted of a dividend at the rate of 4 per cent. per annum, which the Board recommended to be paid. The progress of the works had been most satisfactory. With one exception all the station sites were in the possession of the contractors. With regard to the Holborn-to-Finsbury Park section, the engineer (Mr. A. Ross) reported that at Finsbury Park Station the whole of the shafts, tunnels, and passages were completed ready for the hoists, permanent way, and electrical appliances. At the King's Cross Station the two shafts, the station tunnels, and the passages were completed, and at the Holborn Station the two shafts were sunk to the full depth, and tunnelling was being proceeded with from these in a northerly direction. Possession had not yet been obtained of the site of the Strand Station. Since the commencement of the works good progress had been made generally, and out of an aggregate length of running and station tunnels to be constructed of 12,903 lineal yards, 10,374 had been driven and lined with cast iron.

Lord Farrer seconded the motion for the adoption of the report, which was carried.

CHLORIDE ELECTRICAL STORAGE.

The report for the year ending June 30 shows a trading profit of £17,510. 9s. 1d. After deducting directors' and auditors' fees (to June, 1903), debenture interest, depreciation, provision for bad debts, and interim dividend on preference shares, the available balance for the year is £5,075. 14s. 4d., to which must be added £7,312. 9s. brought forward from last year, making a disposable balance of £12,386. 3s. 4d. The directors propose the payment of a dividend of 6 per cent. on the preference shares for the financial year, less interim dividend already paid, and a dividend of 8 per cent. on the ordinary shares, free of income tax, together amounting to £4,520, and to carry forward the balance, £7,866. 3s. 4d.

NEW COMPANIES REGISTERED.

Weldrivet Boiler and Motor Company, Limited (81,084).—Capital, £12,000. Objects: to acquire the business lately carried on by the Empire Boiler and Engineering Company, Limited, at Ovenden, near Halifax, and to carry on the business of mechanical, electrical, and hydraulic engineers, etc. Registered office: Empire Works, Holmfield, Halifax.

Morris Hawkins Electrical Company, Limited. — Capital, £11,000. Objects: to adopt an agreement with the Morris Aiming Tube and Ammunition Company, Limited, and to carry on the business of electricians, electrical and mechanical engineers, makers of electric tramcars, dynamos, telephones, etc. Registered office: 17, Charing Cross-road, W.C.

Imperial Engineering Supplies Company, Limited.—Capital, £1,500. Object: to carry on the business of suppliers of electrical and engineering fittings and accessories, electric light and power contractors, electrical and mechanical engineers, electricians, etc.

German Laundry Company, Limited. — Capital, £2,000. Object: to acquire the undertaking and assets of the Electric Laundry Company, Limited (incorporated in 1898, now in liquidation). Registered office: 16-26, Rosemont-road, Finchley-road, N.W.

Liens Registered.

Electric Supply Corporation, Limited.—A trust deed, dated July 18, 1904, to secure £50,000 debenture stock, has been registered. Property charged: the company's undertaking and property, present and future, including uncalled capital. Trustees: C. F. Tufnell, Kenley, and J. G. B. Stone, Drapers'-gardens, E.C.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Ipswich.—The Electric Lighting Committee will shortly advertise for tenders for addition of boiler.

Pennas de San Pedro (Spain).—The Municipality require tenders for electric lighting for 20 years. Tenders by Aug. 26.

Paris.—The Posts and Telegraph Department, 123, Rue de Grenelle, require tenders for paper-insulated cables (11 lots) by Aug. 15.

Brazil.—The Municipality of Porto Alegro require tenders for erection, etc., of a generating station for electric lighting and tramway purposes by Aug. 15.

Plymouth.—Tenders are invited for electric light installation at the technical school, Plymouth, for the Plymouth Education Authority.

Digitized by Google

Tenders to Mr. E. Chandler Cook, secretary, 18, Princess-square, Plymouth, by 12 noon on Aug. 15.

Dublin.—The Lighting Committee of the Corporation of the City of Dublin are prepared to receive tenders for the supply of 500 alternating-current meters, single-phase and three-phase. Tenders to the Chairman, Lighting Committee, 3, Cork-hill, Dublin, by 12 noon on Aug. 23.

Hove (Sussex).—Tenders are invited for the supply, delivery, and laying, in the parish of Aldrington, of low-tension vulcanised-bitumen, dialite, or "leadless" paper cables, conduits, boxes, meters, etc. Tenders by Aug. 30. See advertisement.

Plymouth.—The Corporation invite tenders for (25) steam alternator, etc.; (26) Lancashire boilers, with mechanical stokers; steam, exhaust, and other piping; ejector, condenser, valves, etc. Specifications, etc., may be obtained from the Borough Electrical Engineer. Tenders by Aug 15.

Madrid.—The Directorate-General of Administration ("Ministerio de la Gobernación") require tenders for the supply and upkeep for three years of continuous-current arc lamps, with a minimum of 64 lamp-posts. The total upset price is about £7,762. Local representation is necessary. Tenders by Aug. 24.

London, S.W.—The London County Council invite tenders for the manufacture, delivery, and erection of three electric car traversers at certain of the Council's tramway depôts in the South of London. Specification, etc., may be obtained at the County Hall, Spring-gardens, S.W. Tenders by 10 a.m. on Oct. 4.

Penang.—The Municipal Council of George Town, Penang, invite tenders for the supply and delivery of tramcars, complete with motors, controllers, trolleys, etc. Specification, etc., can be obtained at the offices of Messrs. Preece and Cardew, 8, Queen Anne's-gate, Westminster, S.W. Tenders to Mr. R. M. Christie, 4, East India-avenue, London, E.C., by 12 noon on Aug. 24.

Leeds.—The Corporation invite tenders for the supply of two 1,000-kw. turbo-alternators, with condensers, exciters, and high and low tension switchgear for same. Forms of tender, etc., can be obtained from Mr. J. B. Hamilton, general manager, Standard-buildings, City-square, Leeds. Tenders to the Town Clerk by 10 a.m. on Aug. 15.

Perth.—The Corporation invite tenders for the construction and equipment of about 4¾ miles of route length of tramways, constructed as single line with passing places—viz.: (1) permanent way and paving, including copper bonding; (2) overhead equipment; (3) cables, ducts, etc.; (4) cars and equipments; (5) car depôt building. Specifications, etc., can be obtained from the Town Clerk. Tenders before noon on Aug. 16.

Greenwich.—The London County Council invite tenders for the manufacture, delivery, and erection at the tramways electricity generating station at Greenwich of the following plant: two 24in. centrifugal pumps and motors, one 3in. centrifugal pump and motor, two 8in. by 8in. three-throw air-pumps and motors, one 3in. artesian well pump, fixed and rotary strainers, etc. Specifications, etc., may be obtained at the County Hall, Spring-gardens, S.W. Tenders by 10 a.m. on Oct. 4.

Manchester.—The Directors of the Manchester Dock and Warehouse Extension Company, Limited, invite tenders for the wiring (for power and light) and electric lighting of five transit sheds (now in course of erection) on the southerly side of dock No. 9, in the county borough of Salford. Specification, etc., can be obtained at the office of Mr. W. H. Hunter, chief engineer to the Manchester Ship Canal Company, 41, Spring-gardens, Manchester. Tenders to Mr. F. A. Eyre, secretary, Manchester Ship Canal Company, 41, Spring-gardens, Manchester, by 10 a.m. on Aug. 30.

Australian Commonwealth.—Tenders will be received at the office of the Deputy Postmaster-General, Hobart (Tasmania), until noon on Sept. 30, 1904, for the supply and delivery at the General Post Office, Hobart, of one multiple metallic branching switchboard. Specifications may be seen at, and tender forms and conditions obtained from, the General Post Offices at Hobart, Melbourne, Sydney, Adelaide, Brisbane, and Perth. Tenders should be endorsed "Tender for Switchboard," and addressed to the Deputy Postmaster-General, Hobart. Tenders may be deposited in the tender-box at the General Post Office, Hobart, or, if sent by post, must be prepaid and registered. Tenderers must state the name of the country in which the switchboard will be manufactured.

RESULTS OF TENDERS.

Hammersmith.—The tender of Davey, Paxman, and Co., for the supply of Economic boilers with combined superheaters, for the sum of £4,899, has been accepted.

Accumulators.—The A.B.P. Accumulator Company, Limited. Stockton-on-Tees. report an order for 230 cells of their standard S4-11 plate type for shipment to Calcutta.

Alford.—The Urban District Council have accepted the tender of the Alford Gas Company, at £184, or £2 per lamp—discount 3¾ per cent.—for lighting the town with gas or other light.

Southwick.—The Electricity Committee have accepted the offer of the British Westinghouse Company to construct a switchboard gallery at the Southwick power station for the sum of £1,291.

Rochdale.—The Electricity Committee have accepted the tender of W. A. Peters and Sons, Townhead, Rochdale, for erection of the buildings in connection with the extension of the engine-room.

Rotherham.—The Corporation have accepted the following tenders: Callender's Cable and Construction Company, London, cables; Reason Manufacturing Company, Brighton, 2½, 5, and 10 amp. meters; Electrical Company, London, 10, 20, 30, and 50 amp. meters.

Bitumen.—Messrs. Rowland Carr and Co. inform us that the order for bitumen, both for Portsmouth and Pembroke Government Dockyards, have been placed with them through Messrs. Johnson and Phillips.

Walsall.—The Electricity Committee have recommended the Town Council to accept the tender of Babcock and Wilcox for supplying one of their water-tube boilers, with fittings, for the sum of £1,060.

Mond-Gas Plant.—Messrs. John Brown and Co., shipbuilders, of Clydebank, N.B., have placed an order with the Power-Gas Corporation, Limited, 39, Victoria-street, London, S.W., for a complete Mond-gas plant of 4,000 h.p. for generating electricity for general use in their shops.

Penrith (Cumberland).—The Urban District Council have accepted the following tenders for (Section A) two oil or gas engines and dynamos; (B) switchboard and boosters; (C) storage battery; (D) mains: Lancashire Dynamo and Motor Company, Manchester, dynamos, gas engines, and gas suction plant; Kelvin and Jas. White, Limited Glasgow, switchboard and boosters; Pflüger Accumulator Works, London, storage battery; British Insulated and Helsby Cables, Limited, Prescot, Lancashire, cables.

Finchley.—The Urban District Council have received the following tenders for the supply and fixing of brackets and all necessary work for adapting light railway centre poles in the Great North-road as columns for incandescent street-lighting by electricity:

W. T. Skelding and Co. (accepted)	£585	12	6
H. Blackwell	586	12	1
Improved Electric Glow Lamp Company	596	18	3
Reason Manufacturing Company	656	7	0

Fulham.—The Council have received the following tenders for two boilers capable of 14,000lb. per hour at the electricity works:

Stirling Boiler Company, Motherwell, N.B. (accepted)	£2,600
Babcock and Wilcox, Renfrew, N.B.	2,680
Richardsons, Westgarth, and Co., West Hartlepool	2,966
R. Hornsby and Sons, Grantham	2,973
B. R. Rowland and Co., Redditch	2,995
Stirling Company (American), Manchester	3,391

The Council have also accepted tenders for the supply of coal as follows: Firmston and Co., Putney, 2,000 tons of Shirebrook double-screened nuts at 12s. 6d. per ton; Carrington, Sells, Dale, and Co., 1,000 tons of "Crynant" Welsh nuts at 14s. 9d. per ton, and 1,000 tons of "Albert" nuts at 11s. 11d. per ton.

Bristol.—The Electrical Committee have received the following tenders:

H.T. switchgear.—Siemens Bros. and Co., Limited, York-mansion, York-street, Westminster (accepted). Also tendered: British Thomson-Houston Company, Limited, Rugby; Dick, Kerr, and Co., Limited, Abchurch-yard, Cannon-street, E.C.; Ferranti Limited, Hollinwood, Lancashire; Johnson and Phillips, Old Charlton, Kent; Cowans Limited, Springfield-lane, Salford, Manchester; British Westinghouse Company, Limited, Norfolk-street, Strand, London, W.C.; Kelvin and James White, Glasgow.

Water-tube boilers.—Babcock and Wilcox, Limited, 30, Farringdon-street, London, E.C. (accepted). Also tendered: Stirling Boiler Company, Limited, Flemington, Motherwell; B. R. Rowland and Co., Limited, Climax Works, Reddish, near Stockport; Edwin Danks and Co., Limited, Oldbury, near Birmingham.

Two 1,000-kw. three-phase extra high-tension turbo-alternators.—Willans and Robinson, Limited, Victoria Works, Rugby; Dick, Kerr, and Co., Limited (accepted). Also tendered: Siemens Bros. and Co., Limited; British Thomson-Houston Company, Limited; Richardsons, Westgarth, and Co., Limited, Hartlepool Engine Works, Hartlepool; British Westinghouse Company, Limited; Brush Electrical Company, Limited, Falcon Works, Loughborough; C. A. Parsons and Co., Heaton Works, Newcastle-on-Tyne; Bruce Peebles and Co., East Pilton, Edinburgh; Mather and Platt, Limited, Salford Ironworks, Manchester.

Two 500-kw. induction-type motor-generators.—Bruce Peebles and Co., Limited (accepted). Also tendered: Vickers, Sons, and Maxim, Limited, River Don Works, Sheffield; International Electric Company, Clun House, Surrey-street, Strand, W.C.; Electric Construction Company, Bushbury, Wolverhampton; Siemens Bros. and Co., Limited; Richardsons, Westgarth, and Co., Limited; General Electric Company, Limited, 71, Queen Victoria-street, E.C.; Crompton and Co, Limited, Salisbury House, London-wall, E.C.; Electrical Company, Limited, 121-125, Charing Cross-road, W.C.; Dick, Kerr, and Co., Limited; Brush Electrical Company, Limited; British Thomson-Houston Company, Limited; Mather and Platt, Limited; British Westinghouse Company, Limited; Phœnix Dynamo Manufacturing Company, Limited, Thornbury Works, Bradford.

E.H.T. cables.—Siemens Bros. and Co., Limited (accepted). Also tendered: British Insulated Wire Company, Limited, Prescot; Western Electric Company, North Woolwich, London; W. F. Dennis and Co., Limited, 49, Queen Victoria-street, London, E.C.; Callenders, Limited, London; St. Helens Cable Company, Limited, Warrington; W. T. Glover and Co., Limited, Trafford Park, Manchester; W. and T. Henley's, London.

E.H.T. transformers.—British Electric Transformer Company, Limited, Hayes, Middlesex (accepted). Also tendered: British Thomson-Houston Company; International Electric Company; Johnson and Phillips; Ferranti Limited; Electrical Construction Company; British Westinghouse Company, Limited; Crompton and Co., Limited; J. Fowler and Co. (Leeds) Limited, Steam Plough Works, Leeds; Burnand Transformer Company, Limited, 6 and 8, Oxford-street, Regent-road, Salford; Dick, Kerr, and Co., Limited; Brush Electrical Company, Limited; Electrical Company, Limited.

E.H.T. switchgear.—Siemens Bros. and Co., Limited (accepted). Also tendered: Johnson and Phillips; Ferranti Limited; Cowans Limited; Dick, Kerr, and Co., Limited; British Thomson-Houston Company, Limited; British Westinghouse Company, Limited; Kelvin and J. White.

Digitized by Google

BUSINESS NOTES.

TRACTION.

Glasgow.—The Corporation have decided to fix top covers to 100 cars.

Blackpool.—The receipts on Bank Holiday showed an increase of £220. 15s. over last year.

Ipswich.—It is reported that the Corporation are considering an extension of the tramways to Felixstowe.

Leicester.—The Aylestone section is expected to be opened at the end of this month or the commencement of next.

Middlesbrough, Stockton, etc., Bill.—This measure has been read a third time in the House of Lords and passed.

Sheffield.—Improvements have been effected in the car service by abolishing the termini of certain sections and making through routes.

Hartlepool.—The company have commenced to lay the new tramlines to a junction with the West Hartlepool lines at the borough boundary.

Light Railways.—The Board of Trade have confirmed the Woodbridge and Bawdsey and the Bideford, Westward Ho! and Appledore light railway orders.

Grimsby.—A proposal that the Corporation should confer with the company in order to secure an extension of the tramway, has been referred to committee.

Rochdale.—A sub-committee has been appointed to enter into negotiations with the Heywood Corporation for the construction and working of tramways in the latter town.

Speed Trials.—It is reported that the electric railway speed trials are shortly to be resumed on the Marienfelde-Zozzen track, when it is hoped to attain a speed of 150 miles an hour.

Stepney.—The Borough Council have consented to the London County Council using a 1in. slot, instead of a ⅜in. slot as in the case of the County Council's southern system, for the tramways to be laid in the borough.

Spezia (Italy).—The British vice-consul reports that sanction has now been obtained from the various authorities concerned to the project for an electric car service between Spezia and Portovenere, tapping all the intermediate suburbs and villages.

Electric Traction in Germany.—The twenty-fifth anniversary of the introduction of electric traction into Germany by Messrs. Siemens and Halske will shortly be celebrated in Berlin. Up to Oct. 1, 1903, there were some 3,310 miles of rails in use for electric traffic.

Darlington.—At the last meeting of the Town Council it was stated that an attempt was being made to have the restriction against the use of trailers, which had been imposed upon the Council by the Board of Trade, removed, so that they might be employed if at any time it were thought desirable.

Newport.—It is expected that the laying of the line on Stow-hill will be taken in hand in a few days. Some delay has arisen in connection with the supply of the stone setts, and the borough engineer having reported that the quarry to whom the contract had been awarded is not in a position to deliver the material, the contract has been cancelled.

Light Railways for Burma.—When opening the Mandalay electric tramways, the Lieutenant-Governor remarked that there were several places in Lower Burma where short lines would pay remarkably well. His Honour said he was considering the advisability of offering guaranteed dividends from district funds for such a purpose, as had been done in India.

Brighton.—At the meeting of the Steyning East Rural District Council a letter was read from the Board of Trade in connection with the dispute with the Corporation over the tramlines in Dyke-road, the Board stating that they could not withhold the certificate for the trams to run, as they were advised that the line was safe, but such certificate would not prejudice any legal question.

Liverpool.—As the result of an arrangement between the Corporation and the National Telephone Company, all the wires of the latter have been removed from the streets through which the tramway overhead wires pass. The only telephone wires which now cross those of the tramways are a few Post Office telephone trunk wires, and efforts are being made to secure the removal of these.

Yarmouth.—A memorial, signed by tradesmen and residents, was presented at the meeting of the Town Council against the extension to Queen's-road, an alternative route being suggested on the ground that the one selected would interfere with the fishing industry. The Council decided, however, to adhere to the original route, only six votes being recorded in favour of the amendment.

Bury.—The Corporation have adopted the recommendation of the Tramways Committee that an agreement be entered into with the Salford Corporation for a through service between Bury and Manchester, the agreement to be terminable by six months' notice. The negotiations with the Heywood Corporation are in abeyance, no definite communication having been received from the latter.

Bury.—At the meeting of the Town Council last week it was reported that the section of the tramways to the barracks was almost completed. The lines to Whitefield had been opened for traffic, and within a fortnight the Salford system would be coupled up to the Bury system. Arrangements for through running between these places were expected to be concluded shortly, but there had been some delay in the negotiations with Heywood.

Burton-Ashby-Swadlincote.—The Midland Railway Company have entrusted Messrs. Dick, Kerr, and Co., Limited, with the contract to construct rather over 10 miles of light railway linking up Burton-on-Trent, Ashby-de-la-Zouch, and Swadlincote. The main roads are being followed with the exception of a short length, where sleeper construction will be used. The work will be carried out to the drawings and specifications of Messrs. Chas. H. Gadsby and Co., the company's engineers.

Tilbury and Southend Railway.—At the half-yearly meeting the Chairman stated that the company would soon have electric traction. Arrangements were being rapidly made, and they hoped soon to be able to accommodate the Metropolitan and District Railways by having electric traction on the section of the line between Bow and Barking. It was expected that electric traction would be ready at about the first half of next year, when the Metropolitan and District lines would be ready for it.

Aberdare.—On Monday afternoon an extraordinary general meeting of the District Council was held for the purpose of passing the necessary resolution to enable the Council to promote a Bill for the construction of electric tramways, and also to erect a refuse destructor in the town. The resolution was carried unanimously, and the clerk was instructed to take the necessary steps to carry out the resolution of the Council. The proposed tramway will run from Trecynon to Aberaman, and thence to Cwmaman and probably to Aberowmboy.

Newcastle.—On Saturday last the Corporation trams started through running on to the company's lines. Arrangements are being made for the company's cars to run from North Shields into the city, as far as Stanhope-street, every 16 minutes, either at the end of this week or the beginning of next. The Corporation having been approached by the inhabitants for an extension of the tramways to Throckley Park, communicated with the Newburn Urban District Council to know whether the latter would give the project their support. The Urban Council decided to write the Corporation for details.

Gomersal.—At the meeting of the District Council last week a letter was read from the British Electric Traction Company intimating their intention of proceeding with the reconstruction of the Birstall and Gomersal tramway, under the Spen Valley and Morley Light Railways Order, 1902, and the Dewsbury, Batley, and Birstall Tramways Act, 1903, and enclosing drawings showing the position of the tracks and the mode of construction, and asking for the Council's approval thereto. It was stated that the scheme included an extension of the existing line to Clough Mills. The matter was referred to the Highways Committee for consideration.

Chester.—The following are details of the working of the Corporation trams from April 6, 1903, to March 25 last, the revenue account and balance-sheet of which appear in another column; length of line, double 2 miles 21 chains, single 19 chains—total, 2 miles 40 chains; receipts from passengers, £8,881; total receipts, £8,916; working expenditure, £5,332; car mileage, 260,785; passengers, 2,002,835; number of cars available, 12; average revenue per mile, 8·205d.; average cost (including interest and sinking fund), 7·892d.; average number of cars running daily, 8·7; average fare per passenger, 1·064d.; units of energy used, 239,072; cost of energy (at 1¼d. per unit) per mile, 1·604d.

Huddersfield.—The Corporation tramways report for the year ended March 31 last (from which, in another column, we extract the financial statement) echoes the views of the committee appointed to consider the question of depreciation (which were adopted by the Corporation), and which were to the effect that, under any circumstances, not less than 3 per cent. on the total capital outlay should be set aside annually for this purpose. Rigid economy has been practiced in the conduct of the undertaking, and the Tramways Committee hope that the public will show a greater appreciation of the service, so that the rate-in-aid may be dispensed with in the near future. The total receipts amounted to £65,675, against £56,632 for the preceding 12 months.

Lowestoft.—A report was presented at the last meeting of the Council giving the statement of accounts for the year ended July 21. This showed total working expenses of £7,392. 18s., the gross profit carried forward to profit and loss account being £3,334. 10s. 7d. The traffic receipts amounted to £10,377. 15s., and advertisements brought in £349. 13s. 7d. The profit and loss account showed sinking fund charges, £875. 3s. 9d.; interest on loan, £2,684. 18s. 10d. The amount taken from the borough fund was £145. The cars carried 2,309,857 passengers, a number equal to the population of Lowestoft 77 times; the mileage run was 286,730; total cost per car mile, 9·161.; working cost per car mile, 6·181.; total revenue per car mile, 8·97d.

Chesterfield.—A start was made on Tuesday with the work of constructing the tramway extension. Members of the Tramway Committee met in an informal sort of way to see the work begun. The extension is from Storrs-road, Brampton, at the Baslow-road end, and from the market place to Whittington Moor at the other end of the existing line. The length of the whole will be about 3½ miles. The British Insulated and Helsby Cables, Limited, have the contract for the permanent way, amounting to £41,257. The work will be done in short lengths so as to occasion as little inconvenience as possible, and it is anticipated that the whole work, which includes the electrification of the route, will be finished in three months. Most of the material required has already been delivered.

King's Norton.—The report of the Tramways Committee states that with regard to the extension of tramways to Northfield, they have again approached the City of Birmingham Tramways Company as to the terms upon which the company would work the suggested extension of the tramways to Northfield. They are informed that the company are not prepared to consider any arrangement for the working of the same except on the basis of a 21 years' lease of the Northfield tramway; and, in addition, that they would not be willing to accept such lease unless they were granted at the same time a lease for the like period of the Moseley and King's Heath routes. The lease of tramway No. 3A Pebble Mill (road) from the Corporation of Birmingham to the

Digitized by Google

Council has now been executed, and steps are being taken to obtain the approval of the Board of Trade thereto.

Kirkcaldy.—The accounts of the Corporation tramways for the year ending May 15 show traffic receipts £9,934 and total receipts £10,189. Traffic expenses amounted to £3,163; maintenance and repairs, £315; rents, rates, taxes, and insurance, £439; management expenses, £823; and cost of energy, £2,880, while £40 was allocated to depreciation. This leaves a surplus of £7,663, from which has to be deducted £2,012 for interest, £211 contribution to sinking fund (cost of Bill), and £259 contribution to sinking fund (cost of works). There remains a net balance of £50, which has been carried forward. Details of the year's working are as follows: miles run, 301,779; passengers carried, 2,770,936; units of energy (at 1¾d. per unit), 395,071; population last census, 34,063; number of times population carried, 81·3; units of energy per car mile, 1·309; passengers carried per mile, 9·1; average traffic receipts per passenger, ·86d.; total operating expenses per car mile, 5·7d.; total cost per car mile, 8·06d.

Ashton.—The Town Council have confirmed the following recommendation of the Tramways Committee in regard to the negotiations with the Joint Tramways Board for Stalybridge, Hyde, Mossley, and Dukinfield for inter-running over the various sections of the lines of the two authorities: "To accept ½d. for each passenger picked up or brought into Ashton on all routes, the Corporation to pay the Board the net working expenses at an agreed sum per mile when running in Ashton. The Corporation of Ashton to construct the Scotland-street line from the county bridge to the Pitt and Nelson Hotel, and bear all costs and expenses in connection therewith. The Board to join up their King-street (Dukinfield) lines to the Ashton tramways forthwith. The same terms to apply for the power of running into Stalybridge and Dukinfield by Ashton as were offered to the Joint Board for running into Ashton. Failing acceptance of these terms the matter to be submitted to arbitration, the arbitrator to be appointed by an independent party."

Lancashire and Yorkshire Railway.—Speaking of the electrification of the Liverpool and Southport Railway at the general meeting of the company, the Chairman stated that from the beginning of April up to the present time the number of electric trains run between Liverpool and Southport, and Liverpool and Hall-road, had been gradually increased from 25 up to 110 trains per day, and more trains were being put on to displace the steam-trains as the machinery was handed over by the contractors. The directors hoped that before long the full service of trains would be run. Considering the magnitude of the change and the new problems to be faced which had not hitherto been dealt with by any other railway company, the initial troubles had not been as great as might have been expected, and though there had been some delays to trains, the causes of those delays had been tackled one by one and eliminated. The general public had shown its appreciation of the more rapid and more frequent service by travelling in much greater numbers over the railway.

Wolverhampton.—Colonel Von Donop, on behalf of the Board of Trade, inspected the new tramway line from Wolverhampton to Bushbury on Wednesday. A party, including the inspector, Alderman Mander (chairman of the Tramway Committee), Alderman Craddock (vice-chairman), Mr. Brown (the inventor of the system), Mr. H. Kendrick (assistant town clerk), Messrs. Shawfield (electrical engineer), Luntley (tramway manager), Beaumont (deputy borough surveyor), and several other members and officials of the Corporation, entered a special car at Lichfield-street. The car travelled to the terminus without any untoward incident, and everything appeared to be satisfactory. At the bridges near the Great Western Railway works a careful inspection was made to note the distance between the passengers' heads and the structures. Here the tall men were much in requisition, but the margin was found to be sufficient, even when tall hats were worn. The length of the section is 1¾ miles. The service is expected to be opened to-morrow. It is proposed to charge a fare of 1½d. A contract has been entered into for the construction of the Wednesfield-road extension.

Bradford.—The detailed accounts of the Corporation tramway undertaking for the year ended March 31 show that the total receipts amounted to £198,437. On the debit side, salaries and wages accounted for £44,751; generating costs, £33,675; maintenance of cars and buildings, £29,212; maintenance of permanent way, £7,719; maintenance of overhead equipment, £3,301; rent, insurance, etc., £7,820; and compensation, etc., £3,762; while interest and sinking fund absorbed £46,105, the aggregate outgoings amounting to £184,037. This leaves a net profit of £13,399, of which £10,482 is put to balance of surrender value of unexpired leases account, while £2,916 is carried to depreciation account. At the meeting of the Tramways Committee it was asked that a proper balance-sheet should be provided, as distinct from a trading account, for the 12 months, and that the capital expenditure on the permanent way and the overhead equipment should be shown. The capital expenditure on various items since 1902 was also asked for, and it was stated that this information would be forthcoming at a later meeting.

Burton-on-Trent.—The borough electrical engineer, Mr. P. J. Pringle, has favoured us with a preliminary return of the tramways for the first year, which terminated on the 8th inst.: traffic receipts, first eight months, £11,586. 8s. 8d.; last four months, £6,430. 1s. 2d.; total for 12 months, £18,C16. 9s. 10d.; advertising, £308. 7s. 6d., £147. 4s. 2d., £455. 11s. 8d.; miscellaneous £49. 0s. 6d., £6. 19s. 9d., £56. 0s. 3d.; total receipts, £18,528. 1s. 10d.; car mileage, 282 378, 151,361, 433,739; traffic receipts per car mile, 9 84d., 10 20d., 9·97d.; total receipts per car mile, 10·14d., 10·44d., 10·25d.; passengers per car mile, 9·08, 9·39, 9·19; total passengers, 2,566,134, 1,421,766, 3,987,900; traffic receipts per passenger, 1·084d., 1·085d., 1·084d.; total units, 362,827, 196,170. 558,997; units consumed for driving cars, 347,156, 193,035, 540,191; total units per car mile, 1·28, 1·29, 1·28; number of times population carried, 49·3, 27·4, 76·7. The receipts at the time of August Bank Holiday were exceedingly good, and were as follows: Saturday, £104. 0s. 11d.; Sunday. £51. 15s. 4d.; Monday, £125. 3s. 10d.; Tuesday, £64—total, £344. 13s. 11d. These receipts were a record, the previous best being Whit Monday (£112. 1s. 9d.) and the previous August Bank Holiday, which was the opening day (£95. 0s. 9d.). The receipts for Tuesday are a record taking for this day, with the exception of the first day after the opening, when the takings amounted to £73. 0s. 8d. The net surplus on the 12 months' working is approximately £2,000.

North-Eastern Railway.—The report that the company had decided to electrify their line from Newcastle to Shields and from Newcastle to Darlington, has been officially contradicted. It is stated that no such scheme will be entertained until the company have had an extended experience of the working of the Tyneside line. The company have inaugurated a service of electric auto-cars between Scarborough and Filey. The car is of the ordinary bogie saloon type, with clerestory roof, being 52ft. over the head stocks, with an inside width of 7ft. 12in. It is divided into three compartments, that at the forward end being some 15ft. 3in. long, and contains an 80-b.h.p. four-cylinder Wolseley horizontal petrol motor, and generator, while between this and the passenger portion is a gangway to admit of access both to the engine-room and the passenger compartment. A small vestibule at the rear serves as a "van" for the conductor, and also contains a controller for operating the car from the far end, thus obviating the necessity of turning the vehicle round for the return journey. At the half-yearly meeting of the company, Viscount Ridley, who presided, stated that from the traffic point of view the electric system had proved very satisfactory, but the novelty of the system had caused them to be beset with a great many difficulties, which though they were surmounting gradually were real difficulties—difficulties both as to the safety of workmen and passengers, and the convenience of the latter. Although it was very early to speak of profit and loss of the undertaking, 53,402 train miles were run in the half-year up to June 30 at a cost of £4,911. By way of comparison he pointed out that the bookings during the week ended July 9 last and the corresponding week of last year had increased by 25 per cent. and the money by 22 per cent.

Wednesbury.—At a meeting of the Town Council on Monday the Mayor referred to the tramway deadlock. He urged that as the tramway company were not prepared to make some arrangements with the Corporation with regard to the Darlaston and Tipton sections, the Corporation should take a stand in the matter and endeavour to force the company to lay down a new system on the Walsall branch. He thought it was high time the Corporation appealed again to the Board of Trade, and requested them to do something not only to compel the company to electrify the line from Darlaston to Wednesbury, but also to put down new rails between Wednesbury and the Pleck, so that people could travel in comfort and decency. Another member of the Corporation suggested that the company should now be asked for a definite decision. The town clerk defined the position as follows: The Corporation were now quite ready to purchase their portion of the tramway route. The tramway company said they (the Corporation) must buy the depôt at Darlaston with the track, at a cost of £10,000. They had, in their agreement with the lessee company, a clause to the effect that if they purchased the depôt they (the company) would buy it from them within 60 days at the same price. Now the lessee company said if the Corporation purchased the depôt for £10,000, they would not buy it off them. That was the difficulty that had arisen, and the Corporation did not want the depôt on their hands. The difficulty had really cropped up between the two companies, and when they had settled their differences they would be able to carry out the purchase of the track and to lease it to the lessee company. He mentioned that three months ago the Corporation suggested arbitration, but this the tramway company had not accepted. The Council agreed with the Mayor that strong measures should be taken, but no further action was decided upon.

Reading.—At last week's meeting of the Town Council a preliminary statement was presented of the first year's working of the tramways. The passenger receipts amounted to £31,482. 9s. 2d., and £220 odd was derived from advertising on tickets and other small sales, making a total income from all sources of £31,702. The total operating expenses, inclusive of rates, insurances, and all establishment charges, were £18,267, leaving a gross profit of £13,434. Of this, interest on capital (£6,705), sinking fund charges (£5,272), and income tax (estimated at £200), absorbed £12,177, leaving a net profit on the year's working of £1,258. In addition to this there was an unearned contribution of £1,670 derived from capital moneys temporarily on deposit at bankers, bringing the total profit up to £2,927 for the year. There had been no special depreciation charged against the revenue account, but the full cost of repairs and renewals had been charged. The passenger receipts average 9·03d. per car mile run, and sundry receipts ·06d. per car mile, making 9·14d. per car mile from all sources. The operating expenses per car mile were 5·28d., and with the addition of 3·50d. per mile for interest, sinking fund, etc., the total expenses reached 8·78d. per car mile, leaving ·36d. per car mile net profit. The average receipts per passenger was ·98d., which was accounted for by the large number of persons travelling at workmen's fares. The ratio of operating expenses to income was 57 per cent., as against an average of 62½ per cent. for some 40 tramway systems in this country. The number of passengers carried during the year was 7,657,569, or equivalent to the whole of the inhabitants of Reading (estimated at 75 000) being carried 102 times during the year, and the number of car miles run was 831,983. There had been a loss on the Bath-road section, and workmen were also carried at a loss, but notwithstanding this there was a balance of profit on the year's working of £2,927. The tramways engineer and manager (Mr. Binns) was warmly congratulated by several members of the Corporation.

Manchester.—The Corporation have concluded an agreement with the Bucklow Rural District Council, who control the parishes of Northenden, Northern Etchells, Dunham Massey, and Timperley. Under it the Corporation are to take over the powers of the Southern Manchester Tramways Act, 1903, and construct and become the owners of the tramways in the districts named. At the end of 35 years the lines in Timperley and Dunham Massey are to be handed over to the local authority, while those in Northenden and Northern Etchells are to be retained for another seven years. The scheme includes the laying of a line from the end of the Withington tramways at Palatine Bridge, along Northenden-road to Sale, and along Langley-lane to the terminus of the Stockport tramways at Gatley. The line to Dunham Massey and Timperley will be laid on Chester-road between Sale and Altrincham. A tramway is being constructed along Chester-road from the Old Cock Hotel, Stretford, towards Sale. In the course of a week or so the Sale boundary will be reached, and it is expected that the work then will have to stop, as there are certain legal difficulties in the way of Sale allowing Manchester to lay lines in their district at the present time. The Board of Trade have granted the Gorton District Council sanction to borrow £18,926 for the purchase and reconstruction of the tramways in the district, but as Gorton has no tramway system of its own the money will practically be repaid by the Manchester Corporation as rent for the lease of the tramways which they run through the Gorton district. By this arrangement no further cost will fall upon the ratepayers of Gorton. The Manchester Corporation have written to the Gorton Council stating they are prepared to advance the money for the purchase of the tramway undertaking in that district at 3½ per cent., also the money for the reconstruction account at the rate of 3¾ per cent., and that the Tramways Committee have arranged to bear the entire costs in connection with the arbitration proceedings with the old Carriage and Tramways Company. This offer will probably be accepted by the Gorton Council. The traffic returns for last week constitute a record in the history of the undertaking. The number of passengers was 2,702,465. and the receipts came to £13,819. 12s. 9d. The receipts on Bank Holiday amounted to £3,017, also a record.

Corwen, Bettws-y-coed, etc., Railway.—An enquiry was held last week by the Light Railway Commissioners, represented by Colonel G. F. O. Boughey, R.E., C.S.I., Mr. Henry Allan Steward, and Mr. Alan D. Erskine (secretary), respecting the proposed electric railway between Corwen, Bettws-y-coed, and Penmachno. Several influential landowners, including Lord Penrhyn, supported the scheme, but the Hon. C. H. Wynn opposed. Mr. Rhys Williams, barrister, who appeared for the promoters, explained that the first proposed railway would extend from Corwen to Bettws-y-coed for a distance of 23½ miles, and the second railway would be from Bettws to Penmachno, a further distance of nearly five miles. The new railway would be of 1ft. 11½in. gauge, with overhead trolley system similar to Snowdon and Bettws Railway. The first railway would run through 14 villages and towns, and afford a better connection with Carnarvon and Portmadoc. Electric motive power would be obtained from a generating station near Lake Gwynant, and the North-Western Power Company were supporting the promoters in every way; 500 square miles of almost isolated country would benefit by the projected railway. The promoters estimated net receipts per annum of £12,220. Denbigh, Merioneth, and Carnarvon County Councils had passed a resolution favouring the scheme. Mr. James Owen, of Mansfield, Owen, and Co., London, the engineers to the company, stated that for the railway itself £134,000 would be required, but the whole scheme, including the appurtenances, was estimated to cost £250.000. Up to the present 1,975 shares had been allotted, and £1,580 in deposit money had been received. Of those shareholders 171 were residents in the districts interested. The construction of the railway presented no special engineering difficulties. Mr. Graham, who appeared for the opposition, said that a large portion of the estate of the Hon. C. H. Wynn would be irretrievably injured. A proposed embankment would increase the flood on that gentleman's lands some 10 times a year, over some 275 acres. He suggested to the Commissioners that no order could be granted to include such embankment, which he was advised by experts could be easily dispensed with. The Commissioners subsequently communicated their sanction, subject to an arrangement being entered into with Mr. Wynn. The result has caused much satisfaction among the inhabitants.

LIGHTING AND GENERAL.

Bridgend.—The profit on the electric light scheme for the past year was £150.

Batley.—The Batley Working-Men's Club premises are to be lighted by electricity.

Beetle.—New mains are to be laid at an estimated cost of £435 and £75 respectively.

Fenton.—Mr. G. V. Fowler contemplates applying for a lighting provisional order.

North-East Ireland Electricity Bill.—This Bill has been reported for third reading.

Neath.—The Town Council propose to apply for sanction to borrow £3,000 for electric lighting purposes.

Mynyddislwyn.—The question of applying for a provisional order for electric lighting is being discussed.

Electric Lighting (London) Bill.—This Bill has been read a third time and passed in the House of Lords.

Crewe.—Application has been made for sanction to borrow £4,500 for additional plant at the electricity works.

Boston.—The Town Council on Tuesday resolved to put down an electric light installation at a cost of £17,270.

Burnley.—Applications for current have been received by the electrical engineer from one chapel and two churches.

Ootacamund.—The scheme for the electric lighting of Government House will soon be taken in hand.—*Indian Engineering.*

Dover.—The Corporation are considering the question of seeking powers for raising £3,500—£2,000 for meters and £1,500 for free wiring.

Cumberland.—We understand that tenders will be advertised for lighting the Garlands Asylum extension. The estimate for lighting by electricity is £8,000.

Colchester.—The tenders of Messrs. Joslins, Limited, for wiring 40 houses and 10 shops under the prepayment meter system has been accepted by the Town Council.

Bursiem.—An enquiry has been held into the Corporation's application for sanction to borrow £21,000 for electric supply purposes and £10,000 for a refuse destructor.

Spalding.—The Urban District Council have decided to apply for a provisional order for electric lighting with a view to prevent outside companies from obtaining powers.

Boston.—It is proposed that application be at once made for leave to borrow £20,000, which is considered sufficient for the first outlay to carry out the electric lighting order.

Folkestone.—The Town Council have now decided to instal electricity at the town hall, and to make adequate provision for a supply of gas in the event of the electric light failing.

Airdrie.—The Lighting Committee have acquired a site for the generating station and engine-house for the supply of electricity to light the special district of Broxburn and Uphall.

Cannock.—An enquiry has been held into the application of the Urban District Council for sanction to borrow £10,000 for the purpose of supplying electric light and power for the district.

Exmouth.—It appears that Messrs. Crompton have all the machinery ready for installing in the generating station, and hope to commence the supply before the end of the current year.

Change of Title.—The title of the Blackheath and Greenwich District Electric Light Company, Limited, has been altered to South Metropolitan Electric Light and Power Company, Limited.

Plymouth.—An enquiry is to be held on the 18th inst. into the application of the Borough Council for sanction to borrow £20,000 for the electric undertaking and £4,462 for refuse destructor purposes.

Derby.—The Town Council have granted £570 for fitting up a mechanical workshop and an electrical engineering laboratory at the technical college, and application will be made for sanction to borrow £550.

Leyland.—The Urban District Council have received from the Board of Trade an extension of the period for the carrying out of the provisional order for the electric lighting of the town for 12 months from July 23.

Market Harborough.—It has been decided to call a special meeting, if necessary, to consider what steps shall be taken in respect to the proposal of an outside company to supply electricity within the Council's area.

Hebden Bridge.—An electrical exhibition will be held from Oct. 6 to 8 to celebrate the formal opening of the municipal electric supply works, which have been insured for £5,000. The lamps connected number 2,000.

Litherland.—Messrs. Ayrton, Radcliffe, and Co. intend to apply for a provisional order for the supply of electric power to the Council's district. The District Council, however, gave notice some time ago of making a similar application.

London County Council.—The Holborn Borough Council are making representations to the County Council with a view to the adoption of electric lighting for Kingsway, which the latter Council projected illuminating by incandescent gas.

Charing Cross and Strand Electricity Supply Co.—The directors have declared an interim dividend on the ordinary shares at the rate of 8 per cent. per annum for the half-year ended June 30, 1904. Warrants will be posted on the 15th inst.

Wolverhampton.—A switchboard is to be provided at the refuse destructor at a cost of £350. It will also be necessary to carry out alterations to the existing switchboard at a cost of £150. The work is to be done by the Corporation's own men.

Kabul.—The Ameer of Afghanistan, says an Indian paper, contemplates an electric installation in Kabul, which will give both power and light. The fuel bill for his factories last year is said to have been eight lakhs of Kabuli rupees, or upwards of four lakhs calculated in Indian currency.

Glasgow.—Councillor Willcock, convener of the Electricity Committee, is visiting Berlin, at his own expense, in order to inspect the generators which are being manufactured in the German capital for the sub-stations. Mr. W. A. Chamen, the Corporation electrical engineer, accompanies him.

Inverness.—The Town Council have postponed the date of commencing the electric supply, on the suggestion of Edmundson's Electricity Corporation, until the end of next April, so as to avoid the inconvenience of opening the streets before the end of September for laying the cables.

Paddington.—The Borough Council have received notice of intention to apply for a lighting provisional order from the Central Electricity Supply Company, and also from the Paddington Electric Supply Company, which is identified with the former company. Consent is not likely to be granted.

Cheltenham.—An independent expert is to report upon the Council's electric supply undertaking, dissatisfaction having been expressed by a section of the ratepayers. Meantime the Council have passed a resolution of confidence in the Electric Lighting Committee and the electrical engineer.

Digitized by Google

London Gazette.—The partnership between William Henry Heath and John James Reynolds, carrying on business as electrical and general engineers at Mary-street, St. Paul's, Birmingham, Warwick, under the style of the Electrical Power Engineering Company, has been dissolved by mutual consent.

Plymouth.—The Borough Council have agreed to the laying of a cable from the works to the Victoria Wharves at a cost of £430. The annual outlay for interest and sinking fund is estimated at £30, and the income at £70. Similar extensions will be made to York-street, Torrington-place, and Peverell-park.

Chelsea.—The revised specification for wiring the wards of the infirmary for electric light has been referred to the Building Committee of the Guardians for consideration, as well as the issuing of instructions for advertisements for tenders for the work. The erection of a gas-engine and dynamo will probably be recommended.

City and Guilds of London Institute.—Particulars of the session 1904 5 of the courses of instruction at the institute's central technical college, Exhibition-road, for students not under 16 years of age and those at the institute technical college, Finsbury, for students not under 14 years of age, appear in another column.

Felixstowe.—A report has been presented with regard to the electricity works site stating that the lease contains restrictions which very considerably affect the use of the site for the purpose of an electric generating station, and that practically it cannot be used as such. A suggestion to remove the station to a larger site is being considered.

Ware.—The agreement with the North Metropolitan Electricity Company for the taking over and working of the Ware electrical lighting order has been sealed. The agreement provides that the company shall pay £186 and costs for the order, while the Council shall have the right of purchase of the undertaking at the expiration of 14 years.

Cheltenham.—Mr. Swinburne, M.I.C.E., has been asked to report upon the electricity undertaking. The following resolution has been passed: "That as at present advised the committee see no reason to abate their confidence in the Electric Lighting Committee, nor in their selection of a chairman of the committee, nor in the electrical engineer."

Sale of Plant.—The Corporation of Bristol have for immediate disposal two Lancashire boilers, 24ft. by 8ft., 140lb. pressure; four 210-kw. Siemens alternators, 2,000 volts, 93 periods; two 88-kw. Siemens alternators, 2,000 volts, 93 periods; one 52-kw. Siemens-Willans 100-volt direct-current generator. Particulars appear in another column.

Rawtenstall.—The Town Council have held a lighting provisional order for the past five years, but have taken no steps to put it into action on account of the unfavourable character of the area. The chairman of the Electrical Committee suggests that the best solution would be the purchase of energy in bulk from the Lancashire Electric Power Company.

South Shields.—A site has been chosen for the poles and of a wireless telegraph station near South Shields, on the summit of the cliffs which form the northern cheek of Marsden Bay. The motive power, generating plant, etc., will be housed in buildings to be erected between the Marsden coastguard station and the Marsden colliery railway, a few yards inland.

Dewsbury.—The electricity department's balance sheet shows a profit of £1 859, owing to an increase in the sale of current not only to ordinary consumers (£5,761), but also to the traction company (£2,733). A balance of £1,009, after paying £1,235 for interest, £1,475 to sinking fund, and £850 to reserve fund, is very satisfactory, compared with a loss of £378 only two years ago.

Stock Exchange.—Application has been made to the Stock Exchange Committee to allow the Metropolitan District Railway Company's £500,000 4 per cent. perpetual debenture stock, in lieu of the scrip now quoted, to be quoted in the official list. The committee have ordered the Madras Electric Tramways (1904), Limited, £50,000 5 per cent. debenture stock to be quoted in the official list.

North-Eastern Railway.—A dividend of 5 per cent. was declared on Friday at the half-yearly meeting of the company at York, and £20,000 was put to reserve, leaving a balance forward of £40,000. Viscount Ridley, who presided, said the traffic on the electrified portion of the system round Newcastle had proved satisfactory, the number of passengers having increased. All possible steps were being taken to secure the safety and convenience of the travellers.

Finchley.—The Urban District Council have adopted a report of the Highways Committee on an application received from the telegraph department of the General Post Office to lay cables through a number of streets in their district. It is proposed to lay the mains under the footways, and to proceed with the work before the Council's pavement improvements are put in hand. The Department will be informed that any application for erection of pole lines will be considered upon its merits when submitted.

West Bromwich.—An enquiry has been held into the application of the Council for sanction to borrow £1,300 to defray the cost of laying an electric main down Spon-lane. It appears that the tender which has been accepted is for £1,306, or within £6 of the estimate. The borough electrical engineer, Mr. Wray, mentioned that the present plant at the generating station was ample to supply this new demand, and, further, that the charge for power was 1d. per unit, and at this price the Corporation were able to make a profit.

Wednesbury.—The Light and Water Committee in a report issued on Friday recommend that meter rents be not charged to consumers of electricity where the consumer's account amounts to £1 per quarter. Further, that if desired by consumers electricity will be supplied for the outside lighting of shops, either by arc or large Nernst lamps, at a flat rate of 4d. per unit, such lamps being connected to a separate meter. This alternative rate will only be allowed on the conditions that a rent for the extra meter is paid in accordance with the rates stated in the supply regulations, and that no gas, but electricity only, is used inside the premises.

Loughborough.—At the last meeting of the Town Council the Gas Committee reported a communication from Mr. Gadsby stating that the only remaining contracts for machinery other than small items requiring to be let were the booster and mechanical stoker, and that he had invited Messrs. Siemens Bros. to estimate for the booster, as he proposed to adopt a machine of which they make a speciality, and was awaiting their tender, and that he had obtained a quotation from Messrs. Bennis and Co. for two patent double machine stokers (including driving shaft and 2½-h.p. motor for driving same), at the sum of £320. 7s. 10d. The quotation was, in his opinion, a reasonable one, and he recommended its acceptance. The recommendation was adopted.

Penrith.—In their last report the Electric Lighting Sub-Committee state that they have received tenders for the erection of the buildings, and for the supply and fixing of all necessary plant and cables, or mains, and that, together with the surveyor's estimate of work to be executed in his department, the total cost of the whole scheme proposed amounts to £6,850. The scheme adopted by the Council contemplated the use of oil-engines, but, on the advice of the engineer, gas-engines with suction gas plant are now substituted. For the sum of £6,850 the Council will obtain a complete installation of greater capacity, and with buildings of a more substantial type, than was provided in the estimate of £7,507. Application is to be made for sanction to borrow £6,850.

Glasgow.—The gross revenue of the Corporation Electricity Committee for the year ended May 31 amounted to £158,150, and the working expenditure was £61,738. After paying interest on loans and contribution to the sinking fund, and deducting the proportion of the cost of lamps and fittings supplied consequent on the change of voltage, the net balance amounts to £42,522. The committee recommend £32,180 be written off for depreciation, leaving a surplus of £10,341 on the year's working. The committee have repaid to the gas department the debit of the previous year, £13,895, so that there is a debit balance of £3,553, which the committee recommend should be carried forward to next year's account. The total capital expenditure since the starting of the department in 1892 has been £1,119,037.

Durham.—The Electric Supply Committee, which is ambitious of forming a county electric supply system, presented a report at the last meeting of the County Council upon the electric supply and tramway companies within the area. The committee desired authority to engage an expert to ascertain whether a county scheme would be practicable, and the cost of it, with a view to submitting the report of the expert to a conference of the local authorities, and which 77 have expressed their willingness to attend as against 31 who have declined, the remainder not having replied. It was pointed out at the meeting of the Council, however, that expenditure upon the fees of an expert without first obtaining parliamentary sanction would be *ultra vires*, and so the matter was adjourned for further consideration.

Grimsby.—The borough electrical engineer's last report states that during June there had been an increase of 506 private lamps and motors, and an increase of 881 in the total number connected and applied for. The units sold showed an increase on June of last year of 3,212 for traction and 8,606 to private consumers or a total increase of 11,718. The figures for the first quarter of the present year (1904-5) showed that 16,570 were sold for power purposes, as compared with 16,519 for the whole of the previous year (1903-4). The units sold to private consumers during the past quarter for lighting and power were 61,703, as against 35,461; for traction, 112 011, as against 98,444; and for public lighting, 16,913, as compared with 17,422. It is proposed to apply for permission to borrow £2,600 to carry out extensions required during the current financial year.

Mauritius.—The Board of Trade have received from the Government of Mauritius a copy of Ordinance No. 33 of 1903, which was assented to by the acting-governor of the colony on Nov. 19, 1903, regulating the erection and use of stations and machinery for wireless telegraphy. By Section 1 of the present ordinance it is provided that "no telegraphic or electrical station, apparatus, machinery, or implements whatsoever, for the purpose of electrical communications, transmission, emission, or reception of messages, by what is generally known as 'wireless telegraphy,' between any places in Mauritius, or between any place in Mauritius with any place out of Mauritius, shall be erected or used in any place in Mauritius, whether on public or private property, without the sanction of the governor previously obtained." Any person contravening the above provisions is liable to a fine not exceeding Rs.5,000, and to have the apparatus, etc., confiscated.

Maidenhead.—The *Maidenhead Advertiser* comments upon the Maidenhead electric lighting extension as follows: "Parliamentary sanction has at last been given to the application of the Corporation for powers to supply electricity to the parishes of Cookham, Taplow, and Bray, from whence many applications have come. Unfortunately, at the instance of the Eton Rural District Council, the parishes of Hitcham and Burnham were added to the original application, and this called up fierce opposition in the House of Lords from the gas company and the Great Western Railway Company. A modified 'Bermondsey clause' was adopted by the committee to satisfy the gas company, and Hitcham and Burnham were thrown out in response to the crushing case against their inclusion made out by the G.W.R. This, however, called up opposition from the Eton Council in the House of Commons, who practically said, 'If you will not have Hitcham and Burnham you shall not have Taplow.' The mayor, the town clerk, and the engineers appeared before the House of Commons Committee on Thursday last and wiped out the Eton opposition. The Corporation have therefore got what they originally applied for, though at considerable cost both to themselves and their opponents."

Digitized by Google

Hereford.—The Electric Lighting Committee's return showing the output of current for the quarters ended June 25, 1903, and June 24, 1904, contains the following particulars: Units sold for lighting 15,686, against 14,896 the corresponding quarter last year; units sold for power 5,378, against 3,733; total units sold 21,064, against 18,629; equivalent number of 8-c.p. lamps at beginning of quarter 10,900, against 9,372; 8-c.p. lamps added 1,265, against 526; equivalent number of 8-c.p. lamps at end of quarter 12,165, against 9,698; number of arc lamps connected 22, against 20; numbers of meters connected 17, against 14; horse-power of motors connected 50½, against 47.

Lowestoft.—Denmark-road is to be lighted by electric lamps to be fixed on poles at a capital charge of £245. The cost per annum will be £69. 12s. for 24 lamps. At the last meeting of the Electric Lighting Committee the accountant submitted a report of expenditure for the half-year ending June 30, as follows: Expenditure—generation, £2,792; distribution, £31; public lamps £173; rates and taxes, £105; management, £507; insurance, £19; interest and sinking fund, £1,277—total, £4,904. Income—private lighting, £2,089; slot meters, £8; power, £264; traction, £1,401; public lighting, £678; meter rents, £110; sundries, £5—total, £4,555. To be provided from rate, £349. The resident engineer reported that there are now connected to the mains 534 consumers, representing 26,945 8-c.p. lamps. During the month 11 new consumers have been connected, representing 1,347 8-c.p. lamps.

Telephone Purchase.—Mr. Weir, M.P., asked the Postmaster-General on Monday whether he was still negotiating with the National Telephone Company for the purchase of their undertaking; and, if so, when would members of that House be informed of the proposed terms, and whether the London telephone area would be treated separately. Lord Stanley replied: "I am still in negotiation with the National Telephone Company, and the hon. member will recognise that while the negotiations are still in progress it is undesirable to make any statement as to the nature or terms of the arrangement under discussion. Having regard to the date which we have reached, I shall certainly not be in a position to make any communication to the House on this subject before the end of the present session; but if an agreement is arrived at, it shall, as I have already promised, be laid before Parliament before it becomes binding, in order that the House may have an opportunity of considering it."

Hampstead.—At the last meeting of the Borough Council the Lighting Committee recommended the Council to support the Shoreditch Borough Council in their efforts to amend the Supply of Electricity Bill by deleting Clause 6, which is as follows: "Notwithstanding anything in the Electric Lighting Act, 1882, no provisional order authorising the supply of electricity by any undertakers within the district of any local authority shall be granted by the Board of Trade except with the consent of such local authority, unless the Board of Trade, in any case in which the consent of such local authority is refused, are of opinion that, having regard to all the circumstances of the case, such consent ought to be dispensed with, and in such case they shall make a special report, stating the grounds upon which they have dispensed with such consent." The committee also recommended the Council to support the St. Pancras Borough Council in their efforts to amend the Bill so as to prevent actions against electric lighting authorities in respect of vibration unless serious damage or nuisance is occasioned by their works, and in that event to empower them to acquire compulsorily the interests affected. The recommendations were adopted.

Stourbridge.—In April the Urban District Council applied for sanction to a loan of £16,000 for erecting a generating station and other purposes, but it was urged that the Council, instead of providing works of their own, should purchase electricity in bulk from the Midland Electric Corporation, whose mains run up to the northern boundary of Stourbridge. Last week an enquiry was held into an application for sanction to a reduced loan of £4,000 for distribution and cognate purposes only. The Town Clerk (Mr. Goddard) said the agreement with the Midland Corporation was not fully completed, but it was proposed that the flat rate for power should be 1·5d., subject to discounts according to the consumption; and 2·55d. for electric lighting. Mr. J. B. Clarke, electrical engineer, said the estimated capital for laying down mains in the compulsory area and for other items and contingencies was £2,940, and there was £1,000 put down for meters and services, which would repay 5 per cent. Mr. McLean, of the Midland Electric Corporation, said his directors were agreeable to the proviso that the arrangement should end by 12 months' notice on either side. The Inspector intimated that the Board would not sanction the loan till they had the agreement in a completed form before them.

Dumfries.—The Town Council have approved an agreement with the India Rubber, Gutta Percha, and Telegraph Works Company, Limited, Silvertown, for the electric lighting of the town. The Council are to transfer their provisional order to the company, who are to repay the expenses incurred by the Council in connection with the order, and their engineers' fee, amounting in all to about £700, and also an annual sum of £30 for an annual inspection of the works by the Council's engineers. The company are to carry out the installation at their own cost, on a site to be provided by the Council, for which they are to pay an annual rent of £100. They are to pay for the maintenance of the works, including renewals of plant, out of their revenue account, and the Council are to have the option, at any time after the lapse of 7½ years, to acquire the undertaking on paying to the company the amount of the original capital outlay and an additional 25 per cent. The Council are under no obligation to take a supply of electricity from the company either for street-lighting or other purposes. The Council have been advised in their negotiations by Messrs. Buchan and Hogarth, Edinburgh, as their consulting engineers. They have made a provisional arrangement to purchase a site for the works at a cost of about £1,050, but another site, being part of the town's property, will also be put before the company.

Hammersmith.—The annual report of the Borough Council's electric supply undertaking shows a total revenue of £32,725, as against £27,185 for the previous year. The working expenditure amounted to £19,276, leaving a gross surplus of £13,449. Interest and sinking fund charges absorb £11,594, leaving a net profit of £1,855, which is some £800 in excess of the previous year. The units sold totalled 2,223,923, of which 1,897,192 were taken by private consumers, the remainder being used for public lighting. Of the public lamps, 177 are arc lamps and 75 are incandescents. The consumers have increased from 1,226 to 1,469, and the motors connected from 66 to 98. When the land in Fulham Palace-road, on which the electricity works now stand, was purchased by the late Vestry, it was decided that one-half of it should be allocated to the electricity undertaking, and the other half to the general purposes of the Vestry. Subsequently it was found that the undertaking would not for some time require so large an area, and the matter was readjusted and a much smaller area was allocated for the purposes of the electricity station. The cost of the land was charged in the proportions of £1,671 to the electricity undertaking, and £5,329 to the general rate. Having regard to the extension of the electricity works which has been decided upon, and to future extensions, it is essential that the undertaking should have considerably more land than has been allocated to it, and the committee therefore recommended that the whole of the vacant land belonging to the Council and adjoining the electricity works be allocated to the purposes of such work, and that it be referred to the Finance Committee to consider and report as to what financial readjustment this proposal will involve.

Colliery Plant.—A most extensive use of electric machinery is now being made in the United Kingdom by colliery owners for working pumps, haulage gears, coal-cutters, etc. In connection with this movement, Messrs. Ernest Scott and Mountain, Limited, of the Close Works, Newcastle-on-Tyne, report contracts from the Mickley Coal Company for a complete electrical transmission of power plant, including two sets of horizontal coupled compound slow-speed engines of 360 effective horse-power each, and two direct-current generators each of 270 kw., mounted on the engine crankshafts. These dynamos are of the firm's latest type, each dynamo being fitted with 18 poles, and arranged to give the output stated above when running at a speed of 110 revolutions per minute. In addition to the two sets of generating machinery, this contract includes a booster which will raise the pressure of the current at the far end to compensate for the loss in the cables. There are also included a 150-h.p. main and tail haulage gear, complete with friction clutches and electric motor, and two electric winding gears, together with the main and branch cables, main and distributing switchboards, and starting switches, and smaller motors for smiths' shops, etc., at bank. For the Littletown Colliery, near Durham, the same firm have in hand an electrical pumping plant, consisting of a quadruple centrifugal pump to deliver 350 gallons of water per minute against a head of 250ft., this pump being driven by one of Scott and Mountain's multipolar electric motor of 66 effective horse-power, running at a speed of 1,220 revolutions per minute, the motor being placed between the pumps—*i.e.*, a series of two pumps being placed at each side of the motor. The same firm are also supplying for collieries a 30 effective horse-power electric motor for driving an existing haulage gear, and a complete arrangement of motor room switchboards and cables. For the Globe Phœnix Gold Mining Company, which has its mines in Rhodesia, Messrs. Scott and Mountain are supplying one of their latest types of three-phase alternating-current generators of 112 kw. capacity, which will be driven by the company's existing steam-engine at the mine, together with one of their well-known three-throw mining pumps, which will deliver 170 gallons of water per minute against a vertical head of 1,000ft., complete with three-phase induction motor of 40 effective horse-power, switchboards, cables, overhead equipment, starting switches, etc. The firm have lately put on the market a disc machine suitable for working in thin seams, the height of their coal-cutting machine being 14in. This machine can be made to work on rails or skids, the total height from the floor to the top of the machine when on rails being 22in., and when mounted on skids 20in. The firm also report orders for coal-cutting machines for Hamsterley Colliery, Shilbottle Colliery, Old Silkstone Colliery (near Barnsley), Messrs. Newton, Chambers, and Co., Sheffield, and others.

PROVISIONAL PATENTS, 1904.

JULY 28.

16603. Improvements in or relating to electric arc lamps. Adrian Denman Jones and the Jandus Arc Lamp and Electric Company, Limited, Hartham Works, Hartham-road, Holloway-road, London.

16608. Improvements in or in connection with means for electrically operating typewriting machines. Sidney Harper Haywood, 3, Brown-street, Market-street, Manchester.

16613. Improvements in electric time switches. David John Steele and Charles Kratt, 154, St. Vincent-street, Glasgow.

16619. Improvements in electric ignition apparatus for exploding gases in rotary or reciprocating engines. George William Somerville, 68, Owen-street, Accrington.

16637. Improved method of forming electromagnetic coils. William Liebert, 65, Chancery-lane, London.

16662. Improvements in electric motor control systems. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

Digitized by Google

16653. **Improvements relating to starting switches for electric motors.** Stothert and Pitt, Limited, and Walter Pitt, 24, Southampton-buildings, Chancery-lane, London.

16659. **Improvements in electric switches.** Charles Smith, 33, Chancery-lane, London.

16663. **Improvements in electric meters.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

16664. **Improvements in starting resistances for electric meters.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

16667. **Improvements in arc lamps.** William Reginald Ridings, Westinghouse Patent Bureau, Westinghouse-building, Norfolk-street, Strand, London.

JULY 29.

16718. **A self-acting guide for trolley wheels of electric cars to facilitate catching the overhead line in the groove of the trolley wheel.** Albert Berkshire and Patrick Blanchfield Walsh, 16, Kingsland-road, Plaistow, London.

16723. **Improvements in compounding dynamo-electric machines for three-wire systems.** Allgemeine Elektricitäts-Gesellschaft, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, July 31, 1903, being date of application in Germany.) (Complete specification.)

16729. **Improvements in contact shoes for electrically-propelled vehicles.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

16746. **An electric automatic stop motion for lace machines.** Benjamin Joseph Barnard Mills, 23, Southampton-buildings, Chancery-lane, London. (A. Pocheron, F. Cellery, and Co., France.)

16751. **Improvements in and relating to receptacles for elements or accumulators.** Heinrich Paul Rudolf Ludwig and Gustav Adolph Wedekind, 27, Chancery-lane, London. (Complete specification.)

16758. **Improvements in or relating to electrolytic electricity meters.** Charles Orme Bastian, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

16760. **Device for balancing the like poles of magnets or magnetic systems.** Hermann Gercke, 18, Buckingham-street, Strand, London. (Date applied for under Patents Act, 1901, July 31, 1903, being date of application in Germany.) (Complete specification.)

16762. **An improved method and means for joining together the ends of telegraph wires and the like.** Georg E. Schmidmer, 18, Buckingham-street, Strand, London. (Complete specification.)

16764. **Improvements in electric switches.** James Yate Johnson, 47, Lincoln's-inn-fields, London. (Voigt und Haeffner Aktien-Gesellschaft, Germany.)

JULY 30.

16789. **An overhead trolley wire cut-out.** Frank Edwards, 50, High-street, Aston.

16814. **Electric installation for transmitting the time.** David Perret, 40, Chancery-lane, London. (Date applied for under Patents Act, 1901, Aug. 11, 1903, being date of application in Switzerland.) (Complete specification.)

16815. **Armature connection for motor electricity meters.** Julius Geyer, 61, Planufer, Berlin, Germany. (Complete specification.)

16820. **Electric winding-up device for clocks and other chronometrical instruments with or without clockwork.** Jean Baptiste Julien Sallin, 33, Cannon-street, London. (Complete specification.)

16837. **Improvements in connections for electric conductors, more especially intended for use with "earthed" pipes or pipes for protecting electrical conductors.** James Yate Johnson, 47, Lincoln's-inn-fields, London. (Hartmann und Braun Aktien-Gesellschaft, Germany.)

AUGUST 2.

16842. **Convertible electric cable connecting box for twin and single cored or wired waterproof cables.** George William Owen, Knowsley Hall Laundry, Knowsley, near Prescot, Lancs.

16846. **Improvements in time element devices applicable to electric circuit breakers and other apparatus.** John Grice Statter, Norfolk House, Norfolk-street, Strand, London.

16853. **An improved method of signalling for electric tramcars and the like.** George Wright, 15, Holley-gardens, Thorneywood, Nottingham.

16871. **Receiving telegraph instrument.** Charles Reginald Underhill, 23, Southampton-buildings, Chancery-lane, London. (Complete specification.)

16875. **An improved method of indicating the stopping places of electric and other street cars by day and night.** Frank Cochrane, The Rowans, Cheadle, Hulme, Cheshire.

16894. **Improvements in apparatus for electrically indicating the position of railway signals, points, or other gear.** Siemens Bros. and Co., Limited, and Luiz Moraes Gomez Ferreira, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

16894. **A safety cable and suspender for the transmission of electric currents.** Ernest Marsh Ginders, 12, College-road, Moseley, Birmingham.

16910. **Improvements in wet magnetic ore separators.** Arthur Freemore Spooner, 323, High Holborn, London. (Magnetic Ore Separating Company Proprietary, Limited, Victoria.)

16932. **Improvements relating to electromagnetic brakes for vehicles.** Erwin Kramer, 7, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Aug. 7, 1903, being date of application in Germany.) (Complete specification.)

AUGUST 3.

16964. **Improvement in the arrangement for lighting and extinguishing gas by the application of electricity.** George Hill, The Grove, Ashton-on-Mersey, Cheshire.

16968. **An enclosed arc lamp.** William Everitt Cook, 13, Wallness-terrace, Wallness, Pendleton, Manchester.

16978. **Art of electrical signalling.** Charles Reginald Underhill, 23, Southampton-buildings, Chancery-lane, London.

16985. **Improvements in and connected with arc lamps.** Francois de Zea Bermudez, 33, Cannon-street, London.

17006. **Improvements in electromagnetic relays.** Edward Tyer, Frederick Thomas Hollins, and Frederick William Leake, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

17011. **An improved voltaic cell or element.** Philippe Delafon, 53, Chancery-lane, London.

17016. **Improvements in electric motor-control systems.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

17017. **Improvements in electric motor-control systems.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

17018. **Improvements in electro-pneumatic control systems.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

17019. **Improvements in alternating-current meters.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

17020. **Improvements in emergency devices for brake systems.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

17021. **Improvements in electric motor-control systems.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

17022. **Improvements in electric meters.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

17023. **Improvements in electric switches.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

17024. **Improvements in electric controllers for electric circuits.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

17029. **Improvements in connection with guards for trolley wheels of electric tramways and the like.** Reginald Shaw, 18, Southampton-buildings, Chancery-lane, London.

17041. **Improvements in supports or insulators for telegraph and other wires.** Storr Garlake, 47, Lincoln's-inn-fields, London. (W. R. Portingale and H. W. Godwin, Cape Colony.)

17043. **Improvements connected with electric bells, indicators, and domestic telephones.** Shanker Abaji Bhisey, 38, Chancery-lane, London.

AUGUST 4.

17046. **A system of electric traction for railways and tramways.** Arthur Marshall, 38, Sunninghill-terrace, Loampit Hill, Lewisham, London. (Complete specification.)

17051. **Improvements in and relating to electrical switches, known as tumbler switches.** George Sperryn and William Henry Wood, 104, Colmore-row, Birmingham.

17058. **Improvements in apparatus for operating the points of electric tramways.** William Redfern Evans, 55, Market-street, Manchester.

17059. **Improvements in electromagnetic controlling devices.** Henry Mostyn Darrah and Lewis Arthur Hackett, 55, Market-street, Manchester.

17080. **Improvements in magnetic compasses.** Abel Edgar Morrall, New Club, Brighton.

17092. **Improvements in prepayment wattmeters.** Frank Walker, The Westinghouse Patent Bureau, Westinghouse-buildings, Norfolk-street, Strand, London.

17101. **Improvements in emergency brake-control systems.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company United States.)

Digitized by Google

17102. Improvements in air-brake systems and valves therefor. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

17121. Improvements in and relating to the electrolytic deposition of metals. Sherard Osborn Cowper-Coles, 70, Chancery-lane, London.

AUGUST 5.

17130. A new or improved contact breaker for electric ignition for gas and oil engines. Harry Frank Rogers and Frank Edward Brown, 29A, Longmore-street, Birmingham.

17133. An electric governer for internal-combustion engines. George Augustus Edward Roberts, Twyford, near Winchester.

17140. Covering a live electric rail. Richard Parkin, 28, Ingoe-street, Lemington-on-Tyne.

17169. An improved chain for suspending electroliers and the like. Charles Isaac Clements, 77, Colmore-row, Birmingham.

17162. Improvements in telephone and like sound transmitters and receivers, and in apparatus for recording and reproducing the sounds received. Ernest George Craven, 55, Chancery-lane, London.

17168. Improvements relating to gas or vapour electric apparatus. Stanwood Edwards Flitchner, Westinghouse Patent Bureau, Westinghouse-buildings, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, Aug. 10, 1903, being date of application in United States.) (Complete specification.)

17176. Improvements in and connected with electric arc lamps. Georg Peritz, 6, Lord-street, Liverpool.

17181. Improvements in contact devices for apparatus for electrically lighting and extinguishing gas. Johan Fredrik Testor, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

17190. An improvement in the manufacture of electric glow lamps to represent candles. Edward Alfred Gimingham, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

17191. Manufacture of filaments for electric glow lamps. Oliver Imray, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Albert de Madaillan, France.)

17196. Improved manufacture of plates and electrodes for electric accumulators and storage batteries. Georges Schauli and George Petrides, 173, Fleet-street, London.

AUGUST 6.

17201. An improvement in third-rail systems for electric railways. Alfred Edwin Hardaker, 12, Mayfield-road, Eccles, Lancs.

17207. Improvements in and relating to trolley pulleys for electric railways, tramways, and the like. Archibald Welsh, 96, Buchanan-street, Glasgow.

17220. A system of connecting monophase motors having armatures furnished with collectors employed in connection with electric rails and working together in pairs. Union Elektricitäts-Gesellschaft (in liquidation), 27, Chancery-lane, London. (Date applied for under Patents Act, 1901, Aug. 8, 1903, being date of application in Germany.) (Complete specification.)

17236. Improvements in electric transmission poles. John Laing Weller, 4, South-street, Finsbury, London. (Complete specification.)

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Aug. 25, 1904.

1903.

17272. Device for electrically firing blasting cartridges and the like. Grainger.

18853. Electric relays. Armstrong and Orling.

19053. Method of guiding trolley-heads along frogs and crossings attached to overhead wires in connection with electric railways and tramways. Cooley.

20219. Surface contact and like systems of electric traction, and apparatus therefor. Boult and Boult.

21078. Party-line telephone system. Heide. (Lowry.)

22269. Brushes for electrical machines Gibson.

23793. Electrically operated trains. Lüdorf.

1904.

3882 Dynamos. Deutsch.

8297. Systems of electrical distribution. Hewitt. (Date applied for under International Convention, April 25, 1903.)

8321. Receiving apparatus for use in wireless telegraphy. Möller.

8963. Arrangements of electrically-driven fluid-compressing pumps and pressure-controlled electric switches therefor. Hyde.

9397. "Clusters" for incandescence electric lamps. Dale.

9468. Method of and apparatus for heating the charge of electric furnaces. Neuburger and Minet.

14143. Vapour electric lamps or rectifiers. Kruh. (Date applied for under International Convention, June 22, 1903.)

14169. Electromotive apparatus for electric clocks and other mechanism. Palmer.

14814. Clip for clamping or binding the trolley wires to fittings in overhead wire systems of electric traction. Luby and Harris.

14815. Section insulator for overhead wire systems of electric traction. Luby and Harris.

14911. Electric arc lamps. Bellardent. (Date applied for under International Convention, Sept. 5, 1903.)

NOTES.

Report on Naval Boilers.—In connection with the various trials, which have been recorded in these columns from time to time regarding the types of boilers to be used in the navy, the final report of the committee appointed to deal with the question has just been published, in which they recommend the adoption of the Babcock-Wilcox and the Yarrow large-tube types.

The Institution Journal.—The issue of the Institution *Journal* dated July contains Messrs. Edgcumbe and Punga's paper on "Direct-Reading Measuring Instruments for Switchboard Use," with discussion; "The Steam-Turbine as applied to Electrical Engineering," by the Hon. C. A. Parsons, Mr. G. G. Stoney, and Mr. C. P. Martin, with discussion; "The Distribution of Electricity in Shipyards and Engine Works" (Newcastle Section), by Mr. J. A. Anderson, with discussion; and "Steam-Turbines" (Dublin Section), by Mr. F. C. Porto, with discussion.

Yorkshire Electric Power Company's Progress. The power station for this great undertaking is practically complete so far as the structure is concerned, and such rapid progress is being made in the construction of the plant and the laying down of the mains, that the company expect to be quite ready to supply energy by December, in accordance with several contracts which they have already entered into. The exhausters and condensers are partly fixed, the boilers and flues have been practically completed by Messrs. Babcock and Wilcox, the water-drums are being erected, the automatic stokers are already fixed, and an extensive scheme of cables is being proceeded with.

North-East Coast Institution of Engineers and Shipbuilders.—We have received a copy of the *Transactions* of the North-East Coast Institution of Engineers and Shipbuilders, dated July, which contains the resumed discussion on Mr. F. H. Alexander's paper, "Longitudinal Engine-Room Bulkheads in Merchant Vessels in Relation to Transverse Stability when Bilged," with Mr. Alexander's reply; the resumed discussion on Mr. H. M. Wilson's paper, "Automatic Governing of Marine Engines," with Mr. Wilson's reply; and a paper by Engineer-Lieutenant E. F. Baker, R.N., on "The Management of Belleville Boilers at Sea," with the discussion on same.

Live-Rail Precautions.—A correspondent to the *Times* suggests that, in view of the number of accidents recently reported, owing to contact with live rails, it would be advisable that some protective marking should be adopted wherever such rails or fittings are exposed to the public. The marking should be compulsory and uniform throughout the kingdom, and should act as a warning or indication of danger by day or night. He proposes that a black and white chequer or stripe should be used for this purpose and painted on the rails or fittings, universally indicating danger. This is an excellent idea, and we are not sure that it has not been adopted in places.

Centre Poles in Streets.—It will be remembered that a few weeks back the Roads Improvement Association approached the Board of Trade with a view to securing the prohibition of centre poles, while they also made representations upon other matters. The Board has now sent a reply. With reference to centre poles, it does not see its way to recommend their prohibition, but is prepared to exact that these shall not be used without the express consent of the Board. On the question of a statutory limit for the width of roads, the Board does not think it would be advisable to fix one, as such a proceeding might have the effect of prohibiting urgently needed lines. The question of road bridges over railways and canals, the Board state, should be dealt with by the Local Government Board.

Telephone Service to France.—A heavy-gauge telephone circuit having been erected between Calais and Lille, some further experiments have been made in telephonic communication between England and the North of France, and it has been found that it will be possible to extend the service. On and from Sept. 1 communication by users of the Post Office system will be practicable between London and Abbeville, Amiens, Aniche, Anor, Armentieres, Arras, Bethune, Boulogne-sur-Mer, Calais, Cambrai, Denain, Douay, Dunkirk, Fourmies, Lens, Lille, Masnidres, Montreuil, Peronne, Roubaix, St. Omer, St. Quentin, Tourcoing, Valenciennes. The charge for each period of three minutes will be 8s.

Electric Lighting Pamphlet.—An excellent little pamphlet on the advantages to tradesmen of using electric light is published by Messrs. Jacomb Bros., of Wingfield-road, Stratford. The author, Mr. G. Rockley, has been employed by the electricity department of the West Ham Corporation for some years as official canvasser and general outside representative, and in this booklet he strikes out quite a new line, particularly in enlarging upon the special advantages of the electric light from the stock-keeper's standpoint, rather than by relying on the usual arguments to controvert the exaggerated circulars of the gas companies. Many of the reasons advanced by the author in favour of the adoption of electric lighting by tradesmen of all kinds are distinctly cogent. The publishers supply this booklet at the rate of £1. 12s. 6d. for 250, or £5. 5s. per 1,000.

The Forms of Sulphur in Coal.—The *Journal* of the American Chemical Society contains some notes by Mr. E. E. Somermeier on the forms in which sulphur occurs in coal, their calorific values, and their effects on the accuracy of the heating powers, calculated by Dulong's formula. The author observes that the estimation of the calorific value of coal from the ultimate analysis involves the calorific value of the sulphur present. When the amount of sulphur is large, the question is important, especially as to how the heating value is affected by the different forms in which sulphur may occur. The author has studied the question experimentally. Since pyrites does not burn completely in a calorimeter, the samples used were burned with coal. As an average of three determinations with one sample and four with another, the value 2,637 calories for 1 grm. of pyrites was obtained. With 53·2 per cent. of sulphur in the pyrites, the calorific value per gramme of sulphur as pyrites is 4,957 calories; 2,915 calories is the heat of combustion of 1 grm. of sulphur as pyrites under ordinary conditions of combustion.

Tramway up Mont Blanc.—The conditions of a concession to a financial syndicate for an electric tramway up Mont Blanc are, according to the Paris correspondent of the *Standard*, as follows: The line is to start from Le Fayet, St. Gervais, and the route to be followed is to include stations at St. Gervais-les-Bains, Motivon, the Col de Voza, the Pavillon de Bellevue, Mont Lachat, Les Rognes, Tete Rousse, and the summit of the Aiguille du Gouter. The final plans are to be presented within a year of the signing of the decree, and the construction of the railway must be commenced within another year, and prosecuted in such a way that it is completed within a period of six years from the commencement of the work. The gauge of the railway is to be 3·28ft., and the minimum number of journeys to be made daily each way from June 15 to Sept. 15 is fixed at two. The trains will be composed of two carriages, and the maximum speed is to be five miles

Digitized by Google

an hour. The fares will be calculated upon a scale of 2s. per mile, and for goods or luggage the rate is to be 4s. per ton per mile.

Sound-Proof Telephone Apartment.—The *Western Electrician* of Chicago describes a telephone booth manufactured by the Yesbera Manufacturing Company, of Ohio. This booth has double walls. The inside and outside walls both extend to the floor on which the booth stands. The edges of the booth floor fit into grooves ploughed crosswise of the inside walls. The inside walls are first put into position, the edges of the side walls fit into grooves ploughed lengthwise of the front and back walls; screws draw them tightly together at the corners of the booth. The outside walls are put into position and fastened in the same manner as are the inside walls. The ceiling fits over the inside walls, the top over the outside walls, giving a clear air-space on all sides and at the top. The floor rests on felt cushions. The outside and inside walls are held the proper distance apart by four small cushioned blocks at the extreme corners of each side. The doors walls are separate, and swing on different sets of hinges, necessitating the use of an adjustable extension lock, which is supplied with each booth. By this construction the best possible sound-proof qualities are obtained.

Cost of Trackless Trolley Roads.—The figures furnished by the Berlin General Electric Company show that a trackless overhead trolley car capable of holding 22 passengers uses about the same amount of electric current as an ordinary street car with accommodation for 28 passengers, representing a higher cost of some 25 per cent. It should also be remembered that the maintenance of the cars, owing to a greater wearing out of the rolling-stock and extensive need of lubricators, etc., is larger than on track cars, though in the latter case provision has to be made for repairs to the permanent way. The total operating costs worked out at about 4d. per mile. Favourable figures are also given for the operation of the trackless line in the Bila Valley. According to the latest reports, after three months' operation the cost of electric current was double that of a track road. This greater utilisation of current, however, is calculated to represent only one-tenth of the sum which track roads require for interest and maintenance. A large part of the income of these trackless roads is obtained by carrying goods. It has been found that the streets are not at all injured by the trackless cars.

The American Visit.—The programme in connection with the forthcoming visit of the Institution to America has now been finally settled, and contains a large quantity of highly useful information, the substance of which has, however, been given in previous issues of this journal. A special notice intimates that arrangements have been made for the United States Custom House officials to board the steamer "Republic" shortly before arrival in Boston in order to pass the baggage and personal effects, thus obviating any delay on landing. The White Star Company have also kindly agreed to make special provision for facilitating the customs examination and the immediate transport of the luggage to the hotel in Boston by placing the luggage of the whole party together in the baggage room. To enable this to be done, all luggage not specially wanted on the voyage should be dispatched beforehand to Liverpool, each member consigning it to himself, addressed: "Passenger by s.s. 'Republic,' sailing Aug. 25, White Star Line, Canada Dock, Liverpool." This notice does not apply to luggage required in the state-rooms during the voyage, which need not be forwarded in advance. The White Star Company are sending to the members their own baggage-room labels, in addition to which the Institution labels must also be affixed to all articles for the purpose of identification. The labels for the hold previously sent out by the White Star Company are to be discarded, but the state-room labels must be kept for the hand luggage.

The Weybridge Injunction.—The Weybridge Urban District Council has obtained an injunction against the Urban Electric Supply Company, to which it transferred its electric lighting order, restraining the company from supplying the adjoining parish of Walton. The injunction was granted by Mr. Justice Joyce, and the effect of it is to prevent the company from supplying energy outside the Weybridge area, the defendants being prohibited from disturbing the Weybridge roads to lay mains for this purpose. Though we have not the full facts of the case before us, the Urban District Council do not appear to have exhibited much business acumen. It is surely to the advantage of the inhabitants of Weybridge that the company should supply energy at the lowest possible rate. The demand is a prominent factor in the rate, and by going to adjoining districts the company obtains a larger demand, and consequently is able to produce more cheaply. We gather that objection to the generating station at Weybridge was one of the causes for the application for the injunction. His Lordship, however, implied that the company might overcome the difficulty by approaching the Board of Trade for a license to supply energy outside the Weybridge area, and granted a stay of the injunction for this purpose.

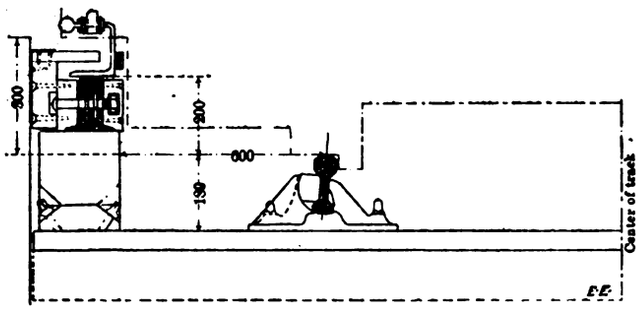
The Telephone Question.—The Postmaster-General has replied, in the form of a parliamentary paper, to a question by Mr. Claude Hay with reference to the transfer of the National Telephone Company's undertaking to the Government. Mr. Hay asked the Postmaster-General "whether, in the event of his coming to an arrangement with the National Telephone Company during the autumn as to the purchase of their undertaking, he will give the House an opportunity of discussing the terms of purchase before the Government are committed to the same, in order that the interests of the users of the telephone and the taxpayers may be properly protected; whether he will agree in any event to refer the agreement (if any) to a Select Committee; and whether, in the event of his deciding to postpone the purchase until 1911, he will reduce the rates of the Post Office service, especially the charge for unlimited service." Lord Stanley reiterates his pledge that no agreement for purchase between the Post Office and the company will be considered binding until the House of Commons has had an opportunity of expressing its opinion thereon. In regard to the rates charged for the Post Office service, Lord Stanley states that this matter must be considered on its merits, apart from any question of purchase.

Hydro-Electric Scheme for Simla.—It is reported that the committee appointed by the Punjab Government to investigate the question of increasing the water supply of Simla will submit its report in a few days. The members have definitely rejected General Beresford-Lovett's scheme, so far as it relates to the pumping of water from the Sutlej, but have, at the same time, decided that the electrical power shall be derived from Nauti Khud. It is understood that they will recommend a modification of a project worked out by the Public Works Department of the Punjab in 1889 for tapping the streams north of Mahasu, where a very ample supply is obtainable. The motive power will, as suggested by the Simla Extension Committee of 1898, be derived from the water of the Naut-Khud stream, and will be transmitted electrically to the pumps, which will be situated in the bottom of the valley below Phagu. If the recommendations of the committee now assembled are accepted, practically all the houses at

Digitized by Google

Mahasu and Mashobra, as far as Naldera, will be served from the new water-mains, and an increase of the supply up to one million gallons a day can be sent into Simla to meet the future demands of population, and still leave a margin for further extensions. The cost of the hydro electric installation will be about 10 lakhs, which sum will not only provide electric power for the pumps in the day-time and electric light at night, but will also include the cost of the laying down of electric mains all over the station for public and private lighting.

Third-Rail System of the Paris-Orleans Railway.—A description is given in the *Street Railway Journal* of the Paris-Orleans Railway Company's extension of their third-rail system. The newly-electrified section, which is some dozen miles in extent, covers the suburban districts between the Paris (Austerlitz) terminus and the important junction at Juvisy. As on the New York Central, the trunk-line trains also will be hauled over the converted section to the terminus by electricity. It will be seen from the accompanying diagram (in which the dimensions are



given in millimetres) that the distance between the running rail and the third rail carrying the current is considerably in excess of the standard practice in England. Thus, while the exact distance between the inner edge of the running rail and the third rail is not given, the dimension shown of 600mm. indicates a distance of considerably over 2ft., whereas the standard agreed upon at the conference of English railway companies was 1ft. 7½in. Again, the height of the third rail is nearly 8in., as against 3in. on English lines. The wooden protection shown is not unlike that which has been adopted in this country for protecting the third rail in stations.

The Labour Market in 1903.—The report of the Labour Department of the Board of Trade for 1903 on the subject of changes in rates of wages and hours of labour in the United Kingdom shows that the coal-mining, iron and steel, engineering, shipbuilding, and glass trades were the ones most affected by the fall in wages during the year. The fall, taking all industries, was, however, less than in the two preceding years. In the industries for which it was possible to obtain definite statistics with regard to the number of persons affected, the report shows that about 897,000 workpeople had their wages changed during 1903. Of this number about 21,000 obtained increases amounting to rather more than £1,500 per week, while 875,000 sustained decreases amounting to more than £39,800 per week. The net result of all the changes reported to the department in 1903 was thus a decrease of £38-300 in weekly wages, compared with decreases of £72,700 in 1902 and £77,300 in 1901. When the various dates at which the changes came into operation are taken into account, the net decrease in the year's wages bill due to the changes recorded in this report may be roughly estimated at £500,000, as compared with decreases of £2,300,000 in 1902 and £1,600,000 in 1901. It is satisfactory to note that in 1903, as also in 1901 and 1902, the number of workpeople whose changes in wages were preceded by a stoppage of work formed but an insignificant fraction of the whole, the percentage affected in 1903 being only 1·5 per cent. of the total. Changes affecting 78 per cent. of the total number of workpeople affected were arranged by conciliation, arbitration, wages boards, sliding scales, or other conciliatory agencies, though these percentages do not take account of abortive strikes. The changes in hours of labour recorded in 1903 were unimportant, but those which took place resulted in a net reduction. The number of workpeople affected was the lowest recorded in any year since the statistics were first collected in 1893.

Wireless Telegraphy Bill.—This measure, upon which we expressed our views a week or two ago, has become law in practically the form of the draft Bill, and it may be of interest to record the attitude of the Government as voiced by Lord Selborne, who moved the second reading in the Upper Chamber. His Lordship stated that the Bill did not attempt to settle once for all the great questions which were beginning to be raised by the introduction of wireless telegraphy—questions which affected the defence of this country, the trade and internal communications of this country, and the progress of the invention, since the measure was of a tentative character, and would expire in two years. In view of experience in the matter of electricity, there was a good deal of disinclination to settle this question in a manner which might have the effect supposed to have been produced by the legislation passed 20 years ago in dwarfing and checking the progress of invention. He thought that the plan adopted by the Government obviated those difficulties and disarmed criticism, and, at the same time, met two very pressing needs. In the first place, it was a standing danger to the defence of this country by land and by sea that there was no method of controlling wireless telegraphy at all. It was perfectly possible for anybody who chose to do so to set up a wireless telegraph installation and to communicate with anybody by sea or across the Channel. It was really a pressing necessity of national defence that power should be taken to control all installations of this kind. A peculiarity of wireless telegraphy was that unless it was controlled its utility might be negatived, and nothing but chaos would supervene. If the coast were studded with wireless telegraph stations under no control and competing with each other, proper communication would be impossible, and ships would not be able to communicate with the shore. Therefore, for the proper civilised use of the invention, control was essential. The third point was that at this transition period it was very important that vested rights should not be allowed to grow up which the State hereafter might have to purchase at an immense cost. These three points were dealt with in the Bill, though no attempt was made to arrive at a permanent settlement.

New South Wales Department of Mines.—The annual report of the New South Wales Department of Mines for the year 1903, just received, contains an abundance of information upon the mining industries of that State. In the first place, the document records that the improvement anticipated was realised, increases being shown in nearly all the metals and minerals found in that region. The value of the year's production was £6,059,486, being a net increase of £421,341 over the previous year. The coal obtained amounted to 6,354,846 tons, representing an increase in value over the previous year of £113,061. The gold produced totalled 295,778oz., signifying an increased value of £395,059. Copper, however, showed the greatest advance, the 9,200 tons obtained indicating an enhanced value of £122,263 over the previous year's

Digitized by Google

output. In regard to iron, however, matters are at a standstill, and nothing is likely to be done until the report of the Royal Commission has been considered by the Federal Government. The total number of persons engaged in the mining industries is estimated at 37,559, as compared with 33,695 during the previous year. An electric apparatus for relighting safety lamps was introduced into several coal collieries. A Jeffrey electrical coal-cutting machine was introduced into one of the mines with satisfactory results, and it is understood that electrical machines will be employed by a number of proprietors in the near future. In one section of the report it is stated that a certain amount of dissatisfaction has been expressed with the mining laws, which are regarded as illiberal compared with those of other countries, and it is considered that more generous provisions in reference to tenure are needed, so as to attract more capital to the mines. It is also considered that the consolidation of the various Acts would be of great benefit, as their number tends to complicate their administration. During the year the Legislative Assembly passed a Bill to regulate wages in coal mines, and another to limit the period of employment below ground in coal mines to eight hours a day, but both were rejected by the Legislative Council. The report states that there is every reason to hope for a continuance of the improvement in the mining industries during the ensuing year.

Electric Traction at Hong Kong.—News reaches us of some successful trials over the completed portion of the new electric railway at Hong Kong, for which Messrs. Dick, Kerr, and Co. are the contractors. The initial run was made at the commencement of last month, the first car to leave the sheds being run under the direction of Mr. Emerson, superintending engineer. Mr. Hackwood inspected on behalf of the consulting engineers, Messrs. Dickinson, of Birmingham. The party in this first car included, besides those above mentioned, Mr. Scott, general manager; Mr. Windsor and Mr. Graham, of Messrs. Dick, Kerr, and Co.; Mr. Graham, of the Callender Cable Company; Mr. Fung Wa Chun; and Mr. Chan A. Tong. The car, leaving the sheds at four o'clock, headed for Bowrington Canal, and then ran along Morrison-hill-road. It returned shortly afterwards along the Praya, and stopped at No. 2 Station. After remaining there for a while it was run back to the sheds. The trial was quite a success, and the car ran smoothly along the rails. After the return of this first car another preliminary run on another car was taken under the direction of Mr. Scott, the general manager, who was accompanied by Mr. A. Course, traffic superintendent, and the staff of inspectors. The same course was travelled over, and with all success. Much interest was taken by those present in the smart behaviour of the Chinese motormen and conductors. Mr. Scott said that so far he had every reason to be quite satisfied with the manner in which they had come through the trial. The organisation of an efficient staff has been no easy matter. The men were all new to the work, and it has been necessary for the Chinese motormen and conductors to learn the names of all the different parts of the car. Henceforward, until the opening of the entire system, the Chinese motormen and conductors are to be subjected to rigid training, and there will be trial trips each day. No pains or expenses are being spared to organise a thoroughly efficient and reliable staff in which the public can place confidence. The opening of the tramways to the public awaits the completion of the track along Arsenal-street. A local journal credits a Celestial who witnessed the opening ceremony with the remark: "No makee pull, no makee pushee, how fashun can makee run?" which observation, or something pretty similar, does not sound altogether unfamiliar.

Electricity in the Philippines.—The Manila correspondent of the *American Electrician* contributes to the August number of that journal an interesting account of the somewhat crude materials which electricians in the Philippine Islands are often compelled to use. After a rather amusing description of the implements employed by native helpers of the Electrical Corps of the United States army, he calls attention to the odd style of combination bamboo poles which one is obliged to use in certain parts of the Philippines, where other stock is not available. Fig. 1 represents one of these combination poles, consisting of a dozen or two of the slender, elastic bamboo pieces united as shown in the illustration, and bound up with wrappings of cord and sometimes wire. The great advantage of this type of pole is, it appears, that it will stand a great deal of typhoon and earthquake without fracturing—no small consideration in that tempestuous region. The poles are often bent over by the high winds, but seldom break. They are difficult for the American wiremen to ascend, but easy to the barefooted native wireman. Cross-arms for poles are often constructed on the rather crude yet effective and practical style shown in Fig. 2. The cross-piece is usually cut through and the pole inserted as shown.

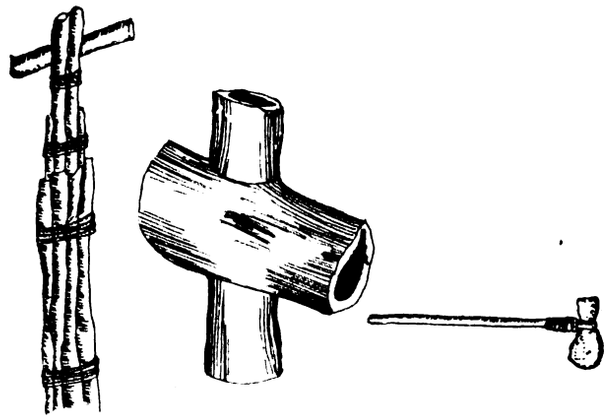


FIG. 1. FIG. 2. FIG 3.

Nails or screws are seldom used; sometimes wooden pins are driven in to secure the parts. The design of hammer frequently observed in the belt of the native wireman is illustrated in Fig. 3. The hammer-head is made of stone or metal, and bound to a handle of hard wood with wrappings of split vegetation, thoroughly dried and exceedingly tough.

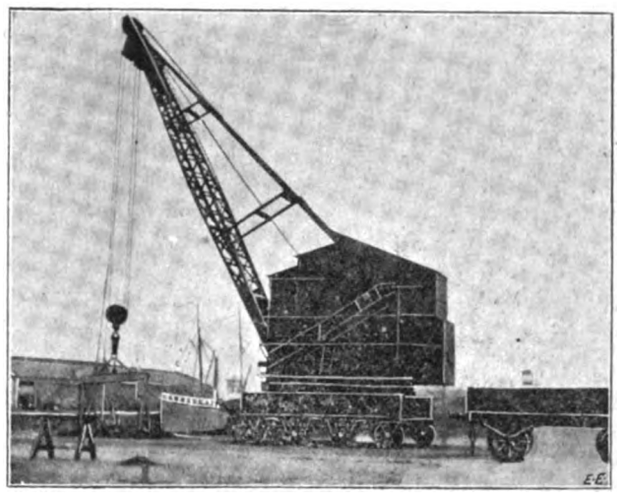
The Pacific Cable.—A White Paper issued by the Government on the Pacific cable contains, in addition to a formal statement of the money issued under the provisions of the Pacific Cable Act, a report by the Pacific Cable Board to the effect that during the year 1903-4 the cable was maintained and remained in efficient working order, and no interruption of any kind occurred. The gross message revenue received during the year was £81,832, and the net message revenue £79,824. The number of messages and words transmitted during the year were 176,351 and 2,095,573 respectively, of which 107,747 messages and 1,226,460 words were inter-Colonial. In January last the Fiji Government opened telegraph communications between Suva and Levuka. The actual expenditure of the Board on the service of the cable during the 12 months ended March 31 last amounted to £54,824, or £25,000 less than the gross receipts. As, however, the Board set aside during the year under review £35,500 as a renewal fund, and as it has also to pay an

Digitized by Google

annuity of £77,544 to meet the interest on its capital and to replace the whole capital in 50 years, the actual deficit amounted to rather more than £88,000, and that sum has to be provided by the contributing Governments. The renewal fund amounted to £52,000, of which £12,500 was held in spare cable. The Board hesitates to make any exact forecast of its probable revenue and expenditure during the current year, but if no contingencies arise, it believes that after providing for the annuity, renewal fund, and working expenses there will be a deficit of £89,810. The Board believes that as one result of the construction of the cable and the competition to which it has led, the average time of transmission between Australasia and the United Kingdom has been sensibly reduced. Arrangements have been made for provisioning outlying stations, and the Board has endeavoured to supply its officers with rational means of amusement. A post office and a Lloyd's signal station have been instituted on Fanning Island, and if a lighthouse were provided the Board considers that the place would be of value to merchant vessels and the navy. The Board is glad to know that a conference will immediately be held in London between the representatives of the various Governments interested in the cable under the presidency of the Secretary of State for the Colonies, with the object of settling certain matters at issue between them, and believes that the meeting will have the effect of solving many difficulties and indirectly promoting the prosperity of the cable.

Electricity in Mining.—A new type of electric locomotive for gathering the coal in mines has been devised by the Jeffrey Manufacturing Company, of Columbus, Ohio, the distinctive feature of which is that it can be operated without earth rails or overhead wires. Locomotives of this type are made with a total height of as low as 29in. A flexible cable, insulated with the best rubber and protected from mechanical injury by heavy braidings, is wound upon a reel, which, with a spooling device, is mounted at one end of the locomotive. The cable is connected to terminals provided for the purpose, and is automatically paid out as the locomotive recedes and rewound upon the reel, in even layers and in uniform tension, as it returns. The cable is of sufficient length to permit the locomotive to reach the greatest depth of rooms found in mining practice. A cable with a single conductor is used when the tracks in the rooms are laid with steel rails, but when the track is laid partly with steel and partly with wooden rails, it becomes necessary, in order to convey the current required, to employ a cable with twin conductors. All electric contacts and conductors are substantially enclosed in dust-proof compartments, so that it is quite impossible for them to be touched accidentally. A standard trolley is provided for use on any portions of the track where there is an overhead wire. The reel is operated by a friction clutch, which is positively driven by a silent running chain and sprocket from the motor, the control of the clutch being placed within easy reach of the man at the operating end of the locomotive. The speed of the cable-reel when the cable is being wound up is such that it tends to produce a slight tension in the unwound portion of the cable; in other words, the cable is wound up faster than the locomotive advances on the track. When the tension of the cable is increased the friction clutch allows the reel to slip, and thus prevents injury to the cable from excessive tension. The clutch can be adjusted to produce any tension desired on the cable, but from practical tests it has been found that about 25lb. is sufficient. Thus, when the locomotive is running the winding of the cable is positive, regardless of speed, and the locomotive can never run over it. When the reel is unwinding the cable, as when the locomotive is going into a room, just enough tension is automatically kept on the cable to prevent it from kinking, should it have a tendency to do so. With this device the cable is not dragged over the ground, but is merely laid down as it is paid out and again picked up as it is rewound upon the reel. The even winding of the cable is accomplished by a spooling device of simple construction. We summarise the preceding from *Dun's Review*.

Electric Coal Cranes in Scotland. — Electric cranes, both for coal loading and general goods work, are going to displace hydraulic cranes in Scottish ports. Glasgow has just placed an order for six cranes for the Clydebank Dock with a Bath firm. Exhaustive trials with a crane in the Princes Dock have led to this action on the part of the Clyde Trustees. At Leith the first electric coal crane was erected—in the Victoria Dock—by a Carlisle firm recently, and at present additional rails are being laid so as to add to its usefulness. It replaced an old steam crane which had been in position for nearly 50 years. In the other docks in Leith the coal hoists are all hydraulic worked, but so great has been the satisfaction with this new one that there is no likelihood of any other cranes being erected but those driven by electricity. This Carlisle (Covans, Sheldon, and Co.) built crane runs upon a railway, 15ft. gauge, and has a normal lifting capacity of 25 tons at a radius of 29ft., although it has been successfully tested with a load of 32 tons. It is



driven by three motors — one for main lifting, one for revolving, and one for derricking. This latter motor is also used for travelling the crane, the change of gear being effected by clutches. The electric current is taken from the town installation, and is conveyed to the crane through a flexible armoured cable into a collector fixed on the crane carriage, and from thence to the switchboard, and so to the different motors. At intervals along the wharf connecting boxes are placed for bringing the flexible cable into contact with the main cable. The carriage upon which the crane is mounted is built of steel, and runs upon four pairs of wheels, the front and back pairs being geared for travelling the crane, and the two centre pairs having sliding bearings on springs to ensure each wheel getting its due proportion of the superincumbent weight. The centre pillar is a steel forging having a solid head, under which runs a series of case-hardened steel rollers. Steel-wire ropes are used, the barrels being large enough to allow of the full length of rope being wound upon them without any overlapping. The main rope is 410ft. long by 4in. in circumference, and that for tipping is 114ft. by 3½in. All the machinery in connection with the crane is enclosed in a large steel house, with windows so arranged that the engineman has a view of the work he has to do.

THE BRITISH ASSOCIATION.

CAMBRIDGE MEETING, 1904.

[BY OUR SPECIAL CORRESPONDENT.]

CAMBRIDGE, *Wednesday.*

This year's meeting of the British Association at Cambridge promises to be a great success, both as regards numbers attending and from the interest of the papers to be read. The accommodation for presidential address and the lectures is already completely filled, and arrivals to-day have mostly been disappointed in their applications for seats. These lectures are respectively:

"The Origin and Growth of the University," by Mr. J. Willis Clark, M.A., in the theatre on Thursday, Aug. 18, at 5.30 p.m.

"Ripple-Marks and Sand-Dunes," by Prof. George Darwin, F.R.S., in the theatre on Friday, Aug. 19, at 8.30 p.m.

"Recent Palaeontological Discoveries in the Rocky Mountains," by Prof. Osborn, of New York, in the theatre on Monday, Aug. 21, at 8.30 p.m.

The sectional programmes, as far as arranged at present, are as follows, but the dates are subject to alteration, and certain additional papers:

SECTION A.—MATHEMATICAL AND PHYSICAL SCIENCE.

Thursday, Aug. 18.

2. "Experiments to decide whether the Ether Moves with the Earth or not," by Prof. W. Wien (Würzburg).
4. "The Reaction of the Radiation on a Moving Electron," by Prof. M. Abraham (Göttingen).
9. A modification of Fitzgerald's model of the ether, by J. Butler Burke.

Monday, Aug. 22.

4. Report of Committee on Electrical Standards.
6. "Standards of Wave-Length," by Prof. Kayser (Bonn).
7. "On the Effect of Electrical Oscillations in Optically Active Bodies," by Prof. W. Voigt (Göttingen).

Tuesday, Aug. 23.

1. "A Correlation between the Electric Conductivity of Air and the Variation of Barometric Pressure," by J. Don.
2. "On the Ionisation of the Atmosphere," by Prof. A. Schuster, F.R.S.
3. Discussion on "The Radioactivity of Ordinary Matter," to be opened by Prof. J. J. Thompson, F.R.S.
6. "Plan of a Combination of Atoms to have the Properties of Polonium or Radium," by Lord Kelvin, F.R.S.
7. "Electrical Insulation in Vacuum," by Lord Kelvin, F.R.S.
8. "Electrical Conductivity of Flames," by Dr. H. A. Wilson.
9. "Electrical Properties of Hot Bodies," by Dr. O. W. Richardson.
10. "The Production of Radioactive Surfaces," by C. E. S. Phillips.
11. "The Kinetic Theory: Determination of the Size of Molecules," by J. H. Jeans.

Wednesday, Aug. 24.

1. "Electric Waves along Spiral Wires, and Applications to Wireless Telegraphy," by Prof. J. A. Fleming, F.R.S.
2. "Magnetic and Electric Properties of Nickel at High Temperatures," by Prof. C. G. Knott.
3. "Eddy-Current Losses in the Lead Sheaths of Three-Phase Cables," by W. B. Field.
4. "On the Viscosity of Colloidal Iron Hydrate," by Dr. A. D. Denning.
5. "Magnetic Double Refraction of Colloidal Iron Hydrate," by Dr. A. D. Denning.
6. "On the Electric and Thermal Conductivities of certain Alloys of Iron," by Prof. W. F. Barrett, F.R.S.
7. "A New Apparatus for Producing Magnetic Fields of Force," by Prof. M. Hartog.

SECTION F.—ECONOMICS AND STATISTICS.

Thursday, Aug. 18.

3. "A Moot Point in the Theory of International Trade," by Prof. F. Y. Edgeworth.
4. "Improvements in Agriculture and their Effect on Economic Rent," by Prof. A. W. Flux.

SECTION G.—ENGINEERING.

Thursday, Aug. 18.

11.30 a.m.—Presidential address.

2 p.m.—"The Origin of Sand Ripples," by Mrs. Ayrton.

Friday, Aug. 19.

1. "Flame Temperatures in Internal-Combustion Motors," by E. Dugald Clerk.
2. "Exhaust Gas Calorimetry," by Prof. B. Hopkinson, to be followed by a general discussion.
3. "The Effects of Receiver Drop in a Compound Engine,' by J. W. Hayward.
4. "Superheated Steam: throttling and other experiments," by A. H. Peake.

Monday, Aug. 22.

1. "The Use of Electricity on the North-Eastern Railway and on Tyneside," by C. H. Merz and W. McLellan.
2. "Electricity from Water Power," by A. A. Campbell Swinton.
3. "Energy Losses in Magnetising Iron," by W. M. Mordey and A. G. Hansard.
4. "Testing Alternating-Current Induction Motors by a Hopkinson Method," by Dr. W. E. Sumpner and R. W. Weekes.
5. "Large-Bulb Incandescent Lamps as Secondary Standards of Light," by Prof. J. A. Fleming.
6. "Some Investigations on the 10-c.p. Harcourt Pentane Lamp made at the National Physical Laboratory," by Clifford Paterson.

Tuesday, Aug. 23.

1. "The Control of the Nile," by Major Sir Hanbury Brown, K.C.M.G.
2. "A Universal Testing Machine of 300 tons for full-sized Members of Structures," by J. H. Wicksteed.
3. "The Effect of Rapidly Alternating Stresses on Structural Steels," by Prof. J. O. Arnold.
4. "A New Process for the Protection of Iron and Steel from Corrosion," by S. Cowper-Coles.
5. "The Electrical Conductivity of certain Aluminium Alloys as affected by Exposure to London Atmosphere, and a Note on their Microstructure," by Prof. E. Wilson.

2 30 p.m.—Lecture on "Indicator Diagrams of a Small Petrol Motor, with Experimental Demonstration," by Prof. H. L. Callendar.

Wednesday, Aug. 24.

1. Report of the Mersey Tidal Regime Committee.
2. "Testing Alternating Motors with Direct Current," by W. Cramp.
3. "The Action of Lightning Strokes on Buildings," by Killingworth Hedges.

SECTION I.—PHYSIOLOGY.

Thursday, Aug. 18.

1. "Reflex and Direct Response to Galvanic and Faradic Currents," by Prof. MacWilliam.

SECTION L.

1. The school-leaving certificate of the Board of Education, University of London, and other examining bodies.
2. The national and local provision for training of teachers.
3. The method of imparting manual instruction (in its broadest sense) in the various grades of schools.
4. "Realistic Arithmetic," by Lieut.-Colonel Mackinlay.
5. "The Place of Hemistic Method in Teaching Experimental Physics," by Dr. R. W. Stewart.
6. "Specialisation in Science Teaching," by J. H. Leonard.
7. Report on "Influence of Examinations upon Teaching."
8. Report on "Courses of Practical, Experimental, and Observational Studies in Elementary Schools."

Address

BY THE RIGHT HON. A. J. BALFOUR, D C L, LL.D, M.P, F.R S., CHANCELLOR OF THE UNIVERSITY OF EDINBURGH, PRESIDENT.

Reflections Suggested by the New Theory of Matter.

The meetings of this great society have for the most part been held in crowded centres of population, where our surroundings never permit us to forget, were such forgetfulness in any case possible, how close is the tie that binds modern science to modern history, the abstract researches of the student to the labours of the inventor and the mechanic. This, no doubt, is as it should be. The interdependence of theory and practice cannot be ignored without inflicting injury on both; and he is but a poor friend to either who undervalues their mutual co-operation.

Yet, after all, since the British Association exists for the advancement of science, it is well that now and again we should choose our place of gathering in some spot where science rather than its applications, knowledge, not utility, are the ends to which research is primarily directed.

If this be so, surely no happier selection could have been made than the quiet courts of this ancient university. For here, if anywhere, we tread the classic ground of physical discovery. Here, if anywhere, those who hold that physics is the true *Scientia Scientiarum*, the root of all the sciences which deal with inanimate nature, should feel themselves at home. For, unless I am led astray by too partial an affection for my own university, there is nowhere to be found, in any corner of the world, a spot with which have been connected, either by their training in youth or by the labours of their maturer years, so many men eminent as the originators of new and fruitful physical conceptions. I say nothing of Bacon, the eloquent prophet of a new era; nor of Darwin, the Copernicus of biology; for my subject to-day is not the contributions of Cambridge to the general growth of scientific knowledge. I am concerned rather with the illustrious line of physicists who have learned or taught within a few hundred yards of this building—a line stretching from Newton in the seventeenth century, through Cavendish in the eighteenth, through Young, Stokes, Maxwell in the nineteenth, through Kelvin (who embodies an epoch in himself) down to Rayleigh, Larmor, J. J. Thomson, and the scientific school centred in the Cavendish laboratory, whose physical speculations bid fair to render the closing years of the old century and the opening years of the new as notable as the greatest which have preceded them.

Now what is the task which these men, and their illustrious fellow-labourers out of all lands, have set themselves to accomplish? To what end led these "new and fruitful physical conceptions" to which I have just referred? It is often described as the discovery of the "laws connecting phenomena." But this is certainly a misleading, and in my opinion a very inadequate, account of the subject. To begin with, it is not only inconvenient, but confusing, to describe as "phenomena" things which do not appear, which never have appeared, and which never can appear, to beings so poorly provided as ourselves with the apparatus of sense-perception. But apart from this, which is a linguistic error too deeply rooted to be easily exterminated, is it not most inaccurate in substance to say that a knowledge of Nature's laws is all we seek when investigating Nature? The physicist looks for something more than what, by any stretch of language, can be described as "co-existences" and "sequences" between so-called "phenomena." He speaks for something deeper than the laws connecting possible objects of experience. His object is physical reality: a reality which may or may not be capable of direct perception; a reality which is in any case independent of it; a reality which constitutes the permanent mechanism of that physical universe with which our immediate empirical connection is so slight and so deceptive. That such a reality exists, though philosophers have doubted, is the unalterable fate of science; and were that faith *per impossibile* to perish under the assaults of critical speculation, science, as men of science usually conceive it, would perish likewise.

If this be so, if one of the tasks of science, and more particularly of physics, is to frame a conception of the physical universe in its inner reality, then any attempt to compare the different modes in which, at different epochs of scientific development, this intellectual picture has been drawn, cannot fail to suggest questions of the deepest interest. True, I am precluded from dealing with such of these questions as are purely philosophical by the character of this occasion, and with such of them as are purely scientific by my own incompetence. But some there may be sufficiently near the dividing line to induce the specialists who rule by right on either side of it to view with forgiving eyes any trespasses into their legitimate domain which I may be tempted during the next few minutes to commit.

Let me, then, endeavour to compare the outlines of two such pictures, of which the first may be taken to represent the views prevalent towards the end of the eighteenth century; a little more than 100 years from the publication of Newton's "Principia," and, roughly speaking, about midway between that epoch-making date and the present moment. I suppose that if at that period the average man of science had been asked to sketch his general conception of the physical universe, he would probably have said that it essentially consisted of various sorts of ponderable matter, scattered in different combinations through space, exhibiting most varied aspects under the influence of chemical affinity and temperature, but through every metamorphosis obedient to the laws of motion, always retaining its mass unchanged, and exercising at all distances a force of attraction on other material masses, according to a simple law. To this ponderable matter he would (in spite of Rumford) have probably added the so-called "imponderable" heat, then often ranked among the elements; together with the two "electrical fluids," and the corpuscular emanations supposed to constitute light.

In the universe as thus conceived, the most important forms of action between its constituents was action at a distance; the principle of the conservation of energy was, in any general form, undreamed of; electricity and magnetism, though already the subjects of important investigation, played no great part in the whole of things; nor was a diffused ether required to complete the machinery of the universe.

Within a few months, however, of the date assigned for these deliverances of our hypothetical physicist came an addition to this general conception of the world, destined profoundly to modify it. About 100 years ago Young opened, or reopened, the great controversy which finally established the undulatory theory of light, and with it a belief in an interstellar medium by which undulations could be conveyed. But this discovery involved much more than the substitution of a theory of light which was consistent with the facts for one which was not; since here was the first authentic introduction* into the scientific world-picture of a new and prodigious constituent—a constituent which has altered, and is still altering, the whole balance (so to speak) of the composition. Unending space, thinly strewn with suns and satellites, made or in the making, supplied sufficient material for the mechanism of the heavens as conceived by Laplace. Unending space filled with a continuous medium was a very different affair, and gave promise of strange developments. It could not be supposed that the ether, if its reality were once admitted, existed only to convey through interstellar regions the vibrations which happen to stimulate the optic nerve of man. Invented originally to fulfil this function, to this it could never be confined, and, accordingly, as everyone now knows, things which from the point of view of sense-perception are as distinct as light and radiant heat, and things to which sense-perception makes no response, like the electric waves of wireless telegraphy,† intrinsically differ, not in kind, but in magnitude alone.

This, however, is not all, nor nearly all. If we jump over the century which separates 1804 from 1904, and attempt to give in outline the world-picture as it now presents itself to some leaders of contemporary speculation, we shall find that in the interval it has been modified, not merely by such far-reaching discoveries as the atomic and molecular composition of ordinary matter, the kinetic

* The hypothesis of an ether was, of course, not new. But before Young and Fresnel it cannot be said to have been established.

† First known through the theoretical work of Maxwell and the experiments of Herz.

Digitized by Google

theory of gases, and the laws of the conservation and dissipation of energy, but by the more and more important part which electricity and the ether occupy in any representation of ultimate physical reality.

Electricity was no more to the natural philosophers in the year 1700 than the hidden cause of an insignificant phenomenon.* It was known, and had long been known, that such things as amber and glass could be made to attract light objects brought into their neighbourhood; yet it was about 50 years before the effects of electricity were perceived in the thunderstorm. It was about 100 years before it was detected in the form of a current. It was about 120 years before it was connected with magnetism; about 170 years before it was connected with light and ethereal radiation.

But to-day there are those who regard gross matter—the matter of everyday experience—as the mere appearance of which electricity is the physical basis; who think that the elementary atom of the chemist, itself far beyond the limits of direct perception, is but a connected system of monads or sub-atoms which are not electrified matter, but are electricity itself; that these systems differ in the number of monads which they contain, in their arrangement, and in their motion relative to each other and to the ether; that on these differences, and on these differences alone, depend the various qualities of what have hitherto been regarded as indivisible and elementary atoms; and that while in most cases these atomic systems may maintain their equilibrium for periods which, compared with such astronomical processes as the cooling of a sun, may seem almost eternal, they are not less obedient to the law of change than the everlasting heavens themselves.

But if gross matter be a grouping of atoms, and if atoms be systems of electrical monads, what are these electrical monads? It may be that, as Prof. Larmor has suggested, they are but a modification of the universal ether, a modification roughly comparable to a knot in a medium which is inextensible, incompressible, and continuous. But whether this final unification be accepted or not, it is certain that these monads cannot be considered apart from the ether. It is on their interaction with the ether that their qualities depend, and without the ether an electric theory of matter is impossible.

Surely we have here a very extraordinary revolution. Two centuries ago electricity seemed but a scientific toy. It is now thought by many to constitute the reality of which matter is but the sensible expression. It is but a century ago that the title of an ether to a place among the constituents of the universe was authentically established. It seems possible now that it may be the stuff out of which that universe is wholly built. Nor are the collateral inferences associated with this view of the physical world less surprising. It used, for example, to be thought that mass was an original property of matter, neither capable of explanation nor requiring it; in its nature essentially unchangeable, suffering neither augmentation nor diminution under the stress of any forces to which it could be subjected; unalterably attached to, or identified with, each material fragment, howsoever much that fragment might vary in its appearance, its bulk, its chemical or its physical condition.

But if the new theories be accepted these views must be revised. Mass is not only explicable, it is actually explained. So far from being an attribute of matter considered in itself, it is due, as I have said, to the relation between the electrical monads of which matter is composed and the ether in which they are bathed. So far from being unchangeable, it changes, when moving at very high speeds, with every change in its velocity.

Perhaps, however, the most impressive alteration in our picture of the universe required by these new theories is to be sought in a different direction. We have all, I suppose, been interested in the generally accepted views as to the origin and development of suns with their dependent planetary systems; and the gradual dissipation of the energy which during this process of concentration has largely taken the form of light and radiant heat. Follow out the theory to its obvious conclusions, and it becomes plain that the stars now visibly incandescent are those in mid-journey between the nebulæ from which they sprang and the frozen darkness to which they are predestined. What, then, are we to think of the invisible multitude of the heavenly bodies in which this process has been already completed? According to the ordinary view, we should suppose them to be in a state where all possibilities of internal movement were exhausted. At the temperature of interstellar space their constituent elements would be solid and inert; chemical action and molecular movement would be alike impossible, and their exhausted energy could obtain no replenishment unless they were suddenly rejuvenated by some celestial collision, or travelled into other regions warmed by newer suns.

This view must, however, be profoundly modified if we accept the electric theory of matter. We can then no longer hold that if the internal energy of a sun were as far as possible converted into heat either by its contraction under the stress of gravitation or by chemical reactions between its elements, or by any other inter-atomic force; and that, were the heat so generated to be dissipated, as in time it must be through infinite space, its whole energy would be exhausted. On the contrary, the amount thus lost would be absolutely insignificant compared with what remained stored up within the separate atoms. The system in its corporate capacity would become bankrupt—the wealth of its individual constituents would be scarcely diminished. They would lie side by side, without movement, without chemical affinity; yet each one, howsoever inert in its external relations, the theatre of violent motions, and of powerful internal forces.

Or, put the same thought in another form. When the sudden appearance of some new star in the telescopic field gives notice to the astronomer that he, and perhaps, in the whole universe, he alone, is witnessing the conflagration of a world, the tremendous forces by which this far-off tragedy is being accomplished must surely move his awe. Yet not only would the members of each separate atomic system pursue their relative course unchanged, while the atoms themselves were thus riven violently apart in flaming vapour, but the forces by which such a world is shattered are really negligible compared with those by which each atom of it is held together.

In common, therefore, with all other living things, we seem to be practically concerned chiefly with the feebler forces of Nature, and with energy in its least powerful manifestations. Chemical affinity and cohesion are on this theory no more than the slight residual effects of the internal electrical forces which keep the atom in being. Gravitation, though it be the shaping force which concentrates nebulæ into organised systems of suns and satellites, is trifling compared with the attractions and repulsions with which we are familiar between electrically charged bodies; while these again sink into insignificance beside the attractions and repulsions between the electric monads themselves. The irregular molecular movements which constitute heat, on which the very possibility of organic life seems absolutely to hang, and in whose transformations applied science is at present so largely concerned, cannot rival the kinetic energy stored within the molecules themselves. This prodigious mechanism seems outside the range of our immediate interests. We live, so to speak, merely on its fringe. It has for us no promise of utilitarian value. It will not drive our mills; we cannot harness it to our trains. Yet not less on that account does it stir the intellectual imagination. The starry heavens have from time immemorial moved the worship or the wonder of mankind. But if the dust beneath our feet be indeed compounded of innumerable systems, whose elements are ever in the most rapid motion, yet retain through uncounted ages their equilibrium unshaken, we can hardly deny that the marvels we directly see are not more worthy of admiration than those which recent discoveries have enabled us dimly to surmise.

Now, whether the main outlines of the world-picture which I have just imperfectly presented to you be destined to survive, or whether in their turn they are to be obliterated by some new drawing on the scientific palimpsest, all will, I think, admit that so bold an attempt to unify physical nature excites feelings of the

* The modern history of electricity begins with Gilbert, but I have throughout confined my observations to the post-Newtonian period.

Digitized by Google

most acute intellectual gratification. The satisfaction it gives is almost æsthetic in its intensity and quality. We feel the same sort of pleasurable shock as when from the crest of some melancholy pass we first see far below us the sudden glories of plain, river, and mountain. Whether this vehement sentiment in favour of a simple universe has any theoretical justification I will not venture to pronounce. There is no *a priori* reason that I know of for expecting that the material world should be a modification of a single medium, rather than a composite structure built out of 60 or 70 elementary substances, eternal and eternally different. Why, then, should we feel content with the first hypothesis and not with the second? Yet so it is. Men of science have always been restive under the multiplication of entities. They have eagerly noted any sign that the chemical atom was composite, and that the different chemical elements had a common origin. Nor, for my part, do I think such instincts should be ignored. John Mill, if I rightly remember, was contemptuous of those who saw any difficulty in accepting the doctrine of "action at a distance." So far as observation and experiment can tell us, bodies *do* actually influence each other at a distance. And why should they not? Why seek to go behind experience in obedience to some *a priori* sentiment for which no argument can be adduced? So reasoned Mill, and to his reasoning I have no reply. Nevertheless, we cannot forget that it was to Faraday's obstinate disbelief in "action at a distance" that we owe some of the crucial discoveries on which both our electric industries and the electric theory of matter are ultimately founded; while at this very moment physicists, however baffled in the quest for an explanation of gravity, refuse altogether to content themselves with the belief, so satisfying to Mill, that it is a simple and inexplicable property of masses acting on each other across space.

These obscure intimations about the nature of reality deserve, I think, more attention than has yet been given to them. That they exist is certain; that they modify the indifferent impartiality of pure empiricism can hardly be denied. The common notion that he who would search out the secrets of Nature must humbly wait on experience obedient to its slightest hint, is but partly true. This may to his ordinary attitude; but now and again it happens that observation and experiment are not treated as guides to be meekly followed, but as witnesses to be broken down in cross-examination. Their plain message is disbelieved, and the investigating judge does not pause until a confession in harmony with his preconceived ideas has, if possible, been wrung from their reluctant evidence.

This proceeding needs neither explanation nor defence in those cases where there is an apparent contradiction between the utterances of experience in different connections. Such contradictions must, of course, be reconciled, and science cannot rest until the reconciliation is effected. The difficulty really arises when experience apparently says one thing and scientific instinct persists in saying another. Two such cases I have already mentioned; others will easily be found by those who care to seek. What is the origin of this instinct, and what its value; whether it be a mere prejudice to be brushed aside, or a clue which no wise man would disdain to follow, I cannot now discuss. For other questions there are, not new, yet raised in an acute form by these most modern views of matter, on which I would ask your indulgent attention for yet a few moments.

That these new views diverge violently from those suggested by ordinary observation is plain enough. No scientific education is likely to make us, in our unreflective moments, regard the solid earth on which we stand, or the organised bodies with which our terrestrial fate is so intimately bound up, as consisting wholly of electric monads very sparsely scattered through the spaces which these fragments of matter are, by a violent metaphor, described as "occupying." Not less plain is it that an almost equal divergence is to be found between these new theories and that modification of the common-sense view of matter with which science has in the main been content to work.

What was this modification of common sense? It is roughly indicated by an old philosophic distinction drawn between what were called the "primary" and the "secondary" qualities of matter. The primary qualities, such as shape and mass, were supposed to possess an existence quite independent of the observer; and so far the theory agreed with common sense. The secondary qualities, on the other hand, such as warmth and colour, were thought to have no such independent existence, being, indeed, no more than the resultants due to the action of the primary qualities on our organs of sense-perception; and here, no doubt, common sense and theory parted company.

You need not fear that I am going to drag you into the controversies with which this theory is historically connected. They have left abiding traces on more than one system of philosophy. They are not yet solved. In the course of them the very possibility of an independent physical universe has seemed to melt away under the solvent powers of critical analysis. But with all this I am not now concerned. I do not propose to ask what proof we have that an external world exists, or how, if it does exist, we are able to obtain cognisance of it. These may be questions very proper to be asked by philosophy; but they are not proper questions to be asked by science. For, logically, they are antecedent to science, and we must reject the sceptical answers to both of them before physical science becomes possible at all. My present purpose requires me to do no more than observe that, be this theory of the primary and secondary qualities of matter good or bad, it is the one on which science has in the main proceeded. It was with matter thus conceived that Newton experimented. To it he applied his laws of motion; of it he predicated universal gravitation. Nor was the case greatly altered when science became as much preoccupied with the movements of molecules as it was with those of planets. For molecules and atoms, whatever else might be said of them, were at least pieces of matter, and, like other pieces of matter, possessed those "primary" qualities supposed to be characteristic of all matter, whether found in large masses or in small.

But the electric theory which we have been considering carries us into a new region altogether. It does not confine itself to accounting for the secondary qualities by the primary, or the behaviour of matter in bulk by the behaviour of matter in atoms; it analyses matter, whether molar or molecular, into something which is not matter at all. The atom is now no more than the relatively vast theatre of operations in which minute monads perform their orderly evolutions; while the monads themselves are not regarded as units of matter, but as units of electricity; so that matter is not merely explained, but is explained away.

Now the point to which I desire to call attention is not to be sought in the great divergence between matter as thus conceived by the physicist and matter as the ordinary man supposes himself to know it, between matter as it is perceived and matter as it really is, but to the fact that the first of these two quite inconsistent views is wholly based on the second.

This is surely something of a paradox. We claim to found all our scientific opinions on experience; and the experience on which we found our theories of the physical universe is our *sense-perception* of that universe. That *is* experience; and in this region of belief there is no other. Yet the conclusions which thus profess to be entirely founded upon experience are to all appearance fundamentally opposed to it; our knowledge of reality is based upon illusion, and the very conceptions we use in describing it to others, or in thinking of it ourselves, are abstracted from anthropomorphic fancies, which science forbids us to believe and Nature compels us to employ.

We here touch the fringe of a series of problems with which inductive logic ought to deal, but which that most unsatisfactory branch of philosophy has systematically ignored. This is no fault of men of science. They are occupied in the task of making discoveries, not in that of analysing the fundamental presuppositions which the very possibility of making discoveries applies. Neither is it the fault of transcendental metaphysicians. Their speculations flourish on a different level of thought; their interest in a philosophy of nature is lukewarm; and howsoever the questions in which they are chiefly concerned be answered, it is by no means certain that the answers will leave

Digitized by Google

the humbler difficulties at which I have hinted either nearer to or further from a solution. But though men of science and idealists stand acquitted, the same can hardly be said of empirical philosophers. So far from solving the problem, they seem scarcely to have understood that there was a problem to be solved. Led astray by a misconception to which I have already referred; believing that science was concerned only with (so-called) "phenomena," that it had done all that it could be asked to do if it accounted for the sequence of our individual sensations, that it was concerned only with the "laws of Nature," and not with the inner character of physical reality; disbelieving, indeed, that any such physical reality does in truth exist—it has never felt called upon seriously to consider what are the actual methods by which science attains its results, and how those methods are to be justified. If anyone, for example, will take up Mill's logic, with its "sequences and co-existences between phenomena," its "method of difference," its "method of agreement," and the rest; if he will then compare the actual doctrines of science with this version of the mode in which those doctrines have been arrived at, he will soon be convinced of the exceedingly thin intellectual fare which has been hitherto served out to us under the imposing title of inductive theory.

There is an added emphasis given to these reflections by a train of thought which has long interested me, though I acknowledge that it never seems to have interested anyone else. Observe, then, that in order of logic sense-perceptions supply the premisses from which we draw all our knowledge of the physical world. It is they which tell us there *is* a physical world; it is on their authority that we learn its character. But in order of causation they are effects due (in part) to the constitution of our organs of sense. What we see depends not merely on what there is to be seen, but on our eyes What we hear depends not merely on what there is to hear, but on our ears. Now, eyes and ears, and all the mechanism of perception, have, as we know, been evolved in us and our brute progenitors by the slow operation of natural selection. And what is true of sense-perception is, of course, also true of the intellectual powers which enable us to erect upon the frail and narrow platform which sense-perception provides, the proud fabric of the sciences.

Now natural selection only works through utility. It encourages aptitudes useful to their possessor or his species in the struggle for existence, and for a similar reason it is apt to discourage useless aptitudes, however interesting they may be from other points of view, because, being useless, they are probably burdensome.

But it is certain that our powers of sense-perception and of calculation were fully developed ages before they were effectively employed in searching out the secrets of physical reality—for our discoveries in this field are the triumphs but of yesterday. The blind forces of natural selection, which so admirably simulate design when they are providing for a present need, possess no power of prevision, and could never, except by accident, have endowed mankind, while in the making, with a physiological or mental outfit adapted to the higher physical investigations. So far as natural science can tell us, every quality of sense or intellect which does not help us to fight, to eat, and to bring up children is but a by-product of the qualities which do. Our organs of sense-perception were not given us for purposes of research; nor was it to aid us in meting out the heavens or dividing the atom that our powers of calculation and analysis were evolved from the rudimentary instincts of the animal.

It is presumably due to these circumstances that the beliefs of all mankind about the material surroundings in which it dwells are not only imperfect, but fundamentally wrong. It may seem singular that down to, say, five years ago our race has, without exception, lived and died in a world of illusions, and that its illusions, or those with which we are here alone concerned, have not been about things remote or abstract, things transcendental or divine, but about what men see and handle, about those "plain matters of fact" among which common-sense daily moves with its most confident step and most self-satisfied smile. Presumably, however, this is either because too direct a vision of physical reality was a hindrance, not a help, in the struggle for existence; because falsehood was more useful than truth, or else because with so imperfect a material as living tissue no better results could be attained. But, if this conclusion be accepted, its consequences extend to other organs of knowledge besides those of perception. Not merely the senses, but the intellect, must be judged by it; and it is hard to see why evolution, which has so lamentably failed to produce trustworthy instruments for obtaining the raw material of experience, should be credited with a larger measure of success in its provision of the physiological arrangements which condition reason in its endeavours to turn experience to account.

Considerations like these, unless I have compressed them beyond the limits of intelligibility, do undoubtedly suggest a certain inevitable incoherence in any general scheme of thought which is built out of materials provided by natural science alone. Extend the boundaries of knowledge as you may; draw how you will the picture of the universe; reduce its infinite variety to the modes of a single space-filling ether; retrace its history to the birth of existing atoms; show how under the pressure of gravitation they became concentrated into nebulæ, into suns, and all the host of heaven; how, at least in one small planet, they combined to form organic compounds; how organic compounds became living things; how living things, developing along many different lines, gave birth at last to one superior race; how from this race arose, after many ages, a learned handful, who looked round on the world which thus blindly brought them into being, and judged it, and knew it for what it was: perform, I say, all this, and, though you may indeed have attained to science, in nowise will you have attained to a self-sufficing system of beliefs. One thing at least will remain, of which this long-drawn sequence of causes and effects gives no satisfying explanation; and that is knowledge itself. Natural science must ever regard knowledge as the product of irrational conditions, for in the last resort it knows no others. It must always regard knowledge as rational or else science itself disappears. In addition, therefore, to the difficulty of extracting from experience beliefs which experience contradicts, we are confronted with the difficulty of harmonising the pedigree of our beliefs with their title to authority. The more successful we are in explaining their origin, the more doubt we cast on their validity. The more imposing seems the scheme of what we know, the more difficult it is to discover by what ultimate criteria we claim to know it.

Here, however, we touch the frontier beyond which physical science possesses no jurisdiction. If the obscure and difficult region which lies beyond is to be surveyed and made accessible, philosophy, not science, must undertake the task. It is no business of this society. We meet here to promote the cause of knowledge in one of its great divisions; we shall not help it by confusing the limits which usefully separate one division from another. It may, perhaps, be thought that I have disregarded my own precept—that I have wilfully overstepped the ample bounds within which the searchers into Nature carry on their labours. If it be so, I can only beg your forgiveness. My first desire has been to rouse in those who, like myself, are no specialists in physics, the same absorbing interest which I feel in what is surely the most far-reaching speculation about the physical universe which has ever claimed experimental support; and if in so doing I have been tempted to hint my own personal opinion that as natural science grows it leans more, not less, upon an idealistic interpretation of the universe, even those who least agree may perhaps be prepared to pardon.

Address to the Engineering Section.

BY HON. CHARLES A. PARSONS, M.A., F.R.S., M I C E., PRESIDENT OF THE SECTION.

On this occasion I propose to devote my remarks to the subject of invention. It is a subject of considerable importance, not only to engineers, but also to men of science and the public generally. I also propose to treat invention in its wider sense, and to include under the word discoveries in physics, mechanics, chemistry, and geology.

Digitized by Google

Invention throughout the Middle Ages was held in little esteem. In most dictionaries it receives scant reference except as applied to poetry, painting, and sculpture. Shakespeare and Dryden describe invention as a kind of muse or inspiration in relation to the arts, and when taken in its general sense to be associated with deceit, as "Return with an invention, and clap upon you two or three plausible lies." As to the opposition and hostility to scientific research, discovery, and mechanical invention in the past, and until comparatively recent times, there can be no question, in some cases the opposition actually amounting to persecution and cruelty.

The change in public opinion has been gradual. The great inventions of the last century in science and the arts have resulted in a large increase of knowledge and the powers of man to harness the forces of Nature. These great inventions have proved without question that the inventors in the past have, in the widest sense, been among the greatest benefactors of the human race. Yet the lot of the inventor until recent years has been exceptionally trying, and even in our time I scarcely think that anyone would venture to describe it as altogether a happy one. The hostility and opposition which the inventor suffered in the Middle Ages have certainly been removed, but he still labours under serious disability in many respects under law as compared with other sections of the community. The change of public feeling in favour of discovery and invention has progressed with rapidity during the last century. Not only have private individuals devoted more time and money to the work, but societies, institutions, colleges, municipalities, and governments have founded many research laboratories, and in some instances have provided large endowments. These measures have increased the number of persons trained to scientific methods, and also provided greatly improved facilities for research; but perhaps one of the most important results to engineers has been the direct and indirect influence of the more general application of scientific methods to engineering.

Sir Frederick Bramwell, in his presidential address to this association in 1888, emphasised the interdependence of the scientist and the civil engineer, and described how the work of the latter has been largely based on the discoveries of the former, while the work of the engineer often provides data and adds a stimulus to the researches of the scientist. And I think his remarks might be further appropriately extended by adding that since the scientist, the engineer, the chemist, the metallurgist, the geologist, all seek to unravel and to compass the secrets of Nature, they are all to a great extent interdependent on each other. But though research laboratories are the chief centres of scientific invention, and colleges, institutions, and schools train the mind to scientific methods of attack, yet in mechanical, civil, and electrical engineering the chief work of practical investigation has been carried on by individual engineers, or by firms, syndicates, and companies. These not only have adapted discoveries made by scientists to commercial uses, but also, in many instances, have themselves made such discoveries or inventions.

To return to the subject, let us for a moment consider in what invention really consists, and let us dismiss from our mind the very common conception which is given in dictionaries and encyclopædias that invention is a happy thought occurring to an inventive mind. Such a conception would give us an entirely erroneous idea of the formation of the great steps in advance in science and engineering that have been made during the last century; and, further, it would lead us to forget the fact that almost all important inventions have been the result of long training and laborious research and long-continued labour. Generally, what is usually called an invention is the work of many individuals, each one adding something to the work of his predecessors, each one suggesting something to overcome some difficulty, trying many things, testing them when possible, rejecting the failures, retaining the best, and by a process of gradual selection arriving at the most perfect method of accomplishing the end in view. This is the usual process by which inventions are made. Then, after the invention, which we will suppose is the successful attempt to unravel some secret of Nature, or some mechanical or other problem, there follows in many cases the perfecting of the invention for general use, the realisation of the advance or its introduction commercially; this after-work often involves as great difficulties and requires for its accomplishment as great a measure of skill as the invention itself, of which it may be considered in many cases as forming a part. If the invention, as is often the case, competes with or is intended to supersede some other method, then there is a struggle for existence between the two. This state of things has been well described by Mr. Fletcher Moulton. The new invention, like a young sapling in a dense forest, struggles to grow up to maturity, but the dense shade of the older and higher trees robs it of the necessary light. If it could only once grow as tall as the rest, all would be easy; it would then get its fair share of light and sunshine. Thus it often occurs in the history of inventions that the surroundings are not favourable when the first attack is made, and that subsequently it is repeated by different persons, and, finally, under different circumstances it may eventually succeed and become established.

We may take in illustration almost any of the great inventions of undoubted utility of which we happen to have the full history—for instance, some of the great scientific discoveries, or some of the great mechanical inventions, such as the steam-engine, the gas-engine, the steamship, the locomotive, the motorcar, or some of the great chemical or metallurgical discoveries. Are not most, if not all, of these the result of the long-continued labour of many persons, and has not the financial side been in most cases a very important factor in securing success? The history of the steam-engine might be selected, but I prefer on this occasion to take the internal-combustion engine, for two reasons—firstly, because its history is a typical one; and, secondly, because we are to hear a paper by that able exponent and great inventor in the domain of the gas-engine, Mr. Dugald Clerk, describing not only the history, but the engine in its present state of development and perfection, an engine which is able to convert the greatest percentage of heat units in the fuel into mechanical work, excepting only, as far as we at present know, the voltaic battery and living organisms.

The first true internal-combustion engine was undoubtedly the cannon, and the use in it of combustible powder for giving energy to the shot is strictly analogous to the use of the explosive mixture of gas or oil and air as at present in use in all internal-combustion engines; thus the first internal-combustion engine depended on the combination of a chemical discovery and a mechanical invention, the invention of gunpowder and the invention of the cannon. In 1680 Huygens proposed to use gunpowder for obtaining motive power in an engine. Papin, in 1600, continued Huygens's experiments, but without success. These two inventors, instead of following the method of burning the powder under pressure, as in the cannon, adopted, in ignorance of thermodynamic laws, an erroneous course. They exploded a small quantity of gunpowder in a large vessel with escape valves, which after the explosion caused a partial vacuum to remain in the vessel. This partial vacuum was then used to actuate a piston or engine and perform useful work. Subsequently several other inventors worked on the same lines, but all of these failed on account of two causes, which now are very evident to us. Firstly, gunpowder was then, as it still is, a very expensive form of fuel, in proportion to the energy liberated on explosion; secondly, the method of burning the powder to cause a vacuum involves the waste of nearly the whole of the available energy, whereas had it been burned under pressure, as in the cannon, a comparatively large percentage of the energy would have been converted into useful work. But even with this alteration, and however perfect the engine had been, the cost of explosives would have debarred its coming into use, except for very special purposes.

We come a century later to the first real gas-engine. Street, in 1794, proposed the use of vapour of turpentine in an engine on methods closely analogous to those successfully adopted in the Lenoir gas-engine of 80 years later, or 30 years ago. But Street's engine failed from crude and faulty construction. Brown, in 1823, tried Huygens's vacuum method, using fuel to expand air instead of gun

Digitized by Google

powder, but he also failed, probably on account of the wastefulness of the method. Wright, in 1833, made a really good gas-engine, having many of the essential features of some of the gas-engines of the present day, such as separate gas and water pumps, and water-jacketed cylinder and piston. Barnett, in 1839, further improved on Wright's design, and made the greatest advance of any worker in gas-engines. He added the fundamental improvements of compression of the explosive mixture before combustion, and he devised means of lighting the mixture under pressure, and his engine conformed closely to the present-day practice as regards fundamental details. No doubt Barnett's engine, so perfect in principle, deserved commercial success, but either his mechanical skill or his financial resources were inadequate to the task; and the character of the patents would seem to favour this conclusion, both as regards Barnett and other workers at this period. Up to 1850 the workers were few, but as time went on they gradually increased in numbers; attention had been attracted to the subject, and men with greater powers and resources appear to have taken the problem in hand. Among these numerous workers came Lenoir, in 1860, who, adopting the inferior type of non-compression engine, made it a commercial success by his superior mechanical skill and resources. Mr. Dugald Clerk tells us: "The proposals of Brown (1823), Wright (1833), Barnett (1838), Bansanti and Matteucci (1857), show gradually increasing knowledge of detail and the difficulties to be overcome, all leading to the first practicable engine in 1866, the Lenoir." This stage of the development being reached, the names of Siemens, Beaude Roches, Otto Simon, Dugald Clerk, Priestman, Daimler, Dowson, Mond, and others, appear as inventors who have worked at and added something to perfect the internal-combustion engine and its fuel, and who have helped to bring it to its present state of perfection.

In the history of great mechanical inventions there is, perhaps, no better example of the interdependence of the engineer, the physicist, and the chemist than is evinced in the perfecting of the gas-engine. The physicist and the chemist together determine the behaviour of the gaseous fuel, basing their theory on data obtained from the experimental engines constructed by the mechanical engineer, who, guided by their theories, makes his designs and improvements. Then, again, from the results of the improvements fresh data are collected and the theory further advance, and so on till success is reached. But though I have spoken of the physicist, the chemist, and the engineer as separate persons, it more generally occurs that they are rolled into one, or at most two, individuals, and that it is indispensable that each worker should have some considerable knowledge of all the sciences involved to be able to act his part successfully.

Now let us ask, Could not this very valuable invention, the internal-combustion engine, have been introduced in a much shorter time by more favouring circumstances, by some more favourable arrangement of the patent laws, or by legislation to assist the worker attacking so difficult a problem? I think the answer is that a great deal might be done, and I will endeavour to indicate some changes and possible improvements. The history of this invention brings before our minds two important considerations. Firstly, let us consider the patentable matter involved in the invention of the gas-engine, the utilisation for motive power purposes of the then well-known properties of the explosive energy of gunpowder or of mixtures of gas and oil with air. Are not these obvious inferences to persons of a mechanical turn of mind, and who had seen guns fired, or explosions in bottles containing spirits of turpentine when slightly heated and a light applied to the neck? Surely no fundamental patent could have been granted under the existing patent laws for so obvious an application of known forces. Consequently, patent protection was sought in comparative details, details in some cases essential to success which were evolved or invented in the process of working out the invention. In this extended field of operations a slight protection was in some instances obtained. But in answer to the question whether such protection was commensurate with the benefits received by the community at large, there can, I think, be only one reply. Generally, those who did most got nothing, some few received insufficient returns, and in very few cases, indeed, can the return be said to have been adequate. The second important consideration is that of the methods of procedure of the patentees, for it appears that very few of them had studied what had been suggested or done before by others before taking out their own patent. We are also struck by the number of really important advances that have been suggested and have failed to fructify, either from want of funds or other causes, to be forgotten for the time and to be reinvented later on by subsequent workers. What a waste of time, expense, and disappointment would be avoided if we in England helped the patentee to find out easily what had been done previously, on the lines adopted by the United States and German Patent Offices, who advise the patentee after the receipt of his provisional specification of the chief anticipatory patents, dead or alive! And ought we in England to rest content to see our patentees awaiting the report of the United States and German Patent Offices on their foreign equivalent specifications before filing their English patent claims? Ought not our Patent Office to give more facilities and assistance to the patentee?

Before proceeding further to discuss some of the possible improvements for the encouragement and protection of research and invention, I ask you to further consider the position of the inventor—the man anxious to achieve success where others have hitherto failed. To be successful he must be something of an enthusiast; and usually he is a poor man, or a man of moderate means, and dependent on others for financial assistance. Generally, the problem to be attacked involves a considerable expenditure of money; some problems require great expenditure before any return can thereby accrue, even under the most favourable circumstances. In the very few cases where the inventor has some means of his own they are generally insufficient to carry him through, and there have unfortunately been many who have lost everything in the attempt. In nearly all cases the inventor has to co-operate with capital; the capitalist may be a sleeping partner, or the capital may be held by a firm or syndicate, the inventor in such cases being a partner—a junior partner—or member of the staff. The combination may be successful and lasting, but unfortunately the best inventors are often bad men of business. The elements of the combination are often unstable, and the disturbing forces are many and active; especially is this so when the problem to be attacked is one of difficulty, necessitating various and successive schemes involving considerable expenditure, generally many times greater than that foreshadowed at the commencement of the undertaking. Under such circumstances, unless the capitalist or the senior partner or board be in entire sympathy with the inventor or exercise great forbearance, stimulated by the hope of ultimate success and adequate returns, the case becomes hopeless, disruption takes place, and the situation is abandoned. Further, in the majority of cases, after some substantial progress has been made it is found that under the existing patent laws insufficient protection can be secured, and the prospect of a reasonable return for the expenditure becomes doubtful. Under such circumstances the capitalist will generally refuse to proceed further unless the prospect of being first in the field may tempt him to continue.

Very many inventors, as I have said, avoid the expense of searching the patent records to see how far their problem has been attacked by others. In some cases the cost of a thorough search is very great indeed; sometimes it is greater than the cost of a trial attack on the problem. In the case of young and inexperienced inventors there sometimes exists a disinclination to enter on an expensive search; they prefer to spend their money on the attack itself. There are some, it is true, who have a foolish aversion to take steps to ascertain if others have been before them, and who prefer to remain in ignorance and trust to chance. It will, however, be said that the United States and German Patent Office reports ought to suffice to warn or protect the English patentee, but my own experience has been that such protection is not entirely satisfactory. There is, firstly, a considerable interval before such reports are received, and the life of a patent is short. Then, if the patent is upon an important subject, attracting

Digitized by Google

general attention, the search is vigorous and sometimes overwrought, and the patent unjustly damaged or refused altogether. If, however, the patent is on some subject not attracting general attention, it receives too little attention, and is granted without comment.

In some few instances it may be said that ignorance has been a positive advantage, and that if the patentee had realised how much of his patentable work was honeycombed by previous publications and patents, he would have lost heart and given up the task. It is, I think, a case of the exception proving the rule, and the patentee ought, as far as possible, in all cases to know his true position, and make his choice accordingly. The present patent law has some curious anomalies. Let us suppose some inventor has the good fortune to place the keystone in the arch of an invention, to add some finishing touch which makes the whole invention a complete success, and valuable. Then, success having been proved possible, others try to reap the results of his labour and good fortune, and, as often happens, it is discovered after laborious search that someone else first suggested the same keystone in some long-forgotten patent or obscure publication, but for some reason or other the public were none the better for his having done so. What does the law do? It says this is an anticipation, and instead of apportioning to all parties reasonable and equitable shares in the perfected invention, to which no one could object, it says that the patent is injured or perhaps rendered useless by the anticipation, and that its value to everyone concerned is thereby diminished or destroyed, as the case may be, and thrown open to the public. Up till a few years ago, any anticipations, however old, might be cited; but recently the law has been amended, and at present none rank as anticipations which are more than 50 years old.

The perfecting of inventions and their introduction into general use requires capital, as we have seen—sometimes a considerable amount, as in the introduction of the Bessemer process for steel, or the linotype system of printing—before any commercial success can be realised. Capital having been found, the next difficulty is in the conservatism of persons and communities who are the buyers of the invention. There is always present in their minds the risk of failure and its consequent loss and worry to themselves, and in the event of success the advantage, in their estimation, may not be sufficient to counterbalance the risk. In large departments and companies whose management is conducted by officials receiving fixed salaries, acting under non-technical supervision, there is a strong tendency among the officials to leave well alone, the organisation being such that the risk of failure, even though it be remote, more than counterbalances, in their estimation, the advantages that would result in the event of success. Next is the opposition of those who are financially interested in competing trades or older inventions, and if the invention is a labour-saving appliance, then the active opposition of the displaced labour is a serious, though generally only a temporary, barrier. Fortunately, however, for the community, for research, and for invention, there is always to be found a considerable percentage of persons who, apart from the inventor, are able and willing to risk, and indeed to sacrifice, their personal interests in the cause of progress for the benefit of the community at large; and were it not for such persons the task of the introduction of most inventions would be an impossible one.

There are many problems of the highest importance in physics, engineering, chemistry, geology, and the arts, of which the investigation might probably prove of great benefit to the human race, and of which the probable monetary cost of the attack would be considerable, and of some very great indeed. Let us, then, enquire how the necessary funds could be raised. It is possible in the case of some of the more attractive problems that a group of rich philanthropists might be found, but in most cases it would be impossible to form a company on business lines under the existing laws of this and other countries, as I shall endeavour to show. In the case of many of the problems, no patents will give adequate protection; in some cases there is no subject matter of novelty and importance involved. In other cases the probable duration of the investigation is so long that any initial patents would have expired before a commercial result was reached, and under either of these circumstances there would be no inducement to business men or financiers to undertake the risk.

As an illustration of my meaning, I will take two investigations that have doubtless occurred to the minds of most of those present, though many others of greater or less importance might be cited. One is the thorough investigation of the problem of aerial navigation, with or without the assistance of flotation by gas. This problem could undoubtedly be successfully solved by an organised attack of skilled and properly-trained engineers and the expenditure of a large sum of money. Assuming the problem solved and commercially successful, it appears to be impossible under the existing patent laws to secure any adequate monopoly so as to justify the expectation of a reasonable return on the capital expended on the invention. For in view of the multitude of suggestions that have been made and the experiments that have been carried out, the practical solution of the problem would appear to rest on a judicious selection of old ideas by means of exhaustive experiments.

Another and perhaps more important investigation which has not, as yet, been attacked to any material extent, is the exploration of the lower depths of the earth. At present the deepest shaft is, I believe, at the Cape, of a little over one mile in depth, and the deepest borehole is one made in Silesia, by the Austrian Government, of about the same depth. What would be found at greater depths is at present a matter for conjecture, founded on the dip and thicknesses of strata observed on or near the surface Much money and many valuable lives have been devoted to exploration of the polar regions, but there can be no comparison between the scientific interest and the possible material results of such exploration and the one I have chosen for illustration of the inadequate protection afforded by law—namely, a great engineering attack on a problem of geology.

I would ask you to consider the commercial aspect of this engineering geological enterprise, as compared with exploration into new or unknown areas on the surface of the earth. An exploring expedition into a new country has before it generally the probability of the acquisition of territorial and mineral rights or possessions bringing material gain to the undertakers. The rights of such enterprises are well known, and capital can be obtained with or without national support, as the case may be. On the other hand, the explorer into the depths of the earth has no rights or monopolies beyond the mineral rights of the land he has purchased over his boring; further, it is improbable that he can obtain any patent of substantial value for his methods of boring to great depths. To succeed in the undertaking a great expenditure of money must be incurred, an expenditure far greater than that of an exploring expedition, and analogous to that of a military expedition or a small invading army, and to raise this sum the pioneers have practically no security to offer. For if they succeed in finding rich deposits of precious minerals in greater abundance, or succeed in making some geological discovery associated with deep borings, they gain no exclusive title to these under existing laws. Any other person or syndicate acting upon the experience gained could sink other shafts in other places or countries, and, benefiting by the experience gained by the pioneers, could probably carry out the work more advantageously, and thus depreciate the first undertaking or render it valueless, as has often occurred before.

Let us consider more closely some of the essential features of sinking a shaft to a great depth, for I think it will be seen that it presents no unsurmountable difficulties beyond those incidental to an enterprise of considerable magnitude, involving the ordinary methods of procedure and the ordinary methods adopted by mining engineers. That there would be some departures from ordinary practice on account of the great depth it is true, but these are more of the character of detail. On the design of this boring I have consulted Mr. John Bell Simpson, the eminent authority on mining in the North of England. The shaft would be sunk in a locality to avoid as far as possible water-bearing strata and the necessity of pumping. It would be

Digitized by Google

of a size usual in ordinary mines or coal pits. The exact position of such shaft would require some consideration as to whether it should commence in the primary or secondary strata. It would be sunk in stages, each of about half a mile in depth, and at each stage there would be placed the hauling and other machinery, to be worked electrically, for dealing with each stage. The depth of each stage would be restricted to half a mile in order to avoid a disproportionate cost in the hauling machinery and the weight of rope, as well as increased cost in the cooling arrangements arising from excessive hydraulic pressures. At each second or third mile in depth there would be air-locks to prevent the air pressure from becoming excessive owing to the weight of the superincumbent air, which at from two to three miles would reach about double the atmospheric pressure at the surface. A greater rise of pressure than this would be objectionable for two reasons—firstly, from the inconvenience to the workmen; secondly, from the rise of temperature due to the adiabatic compression of the circulating air for ventilating purposes. The air-pressure immediately above each air-lock would thus reach to about two atmospheres, and beneath to one atmosphere. In order to carry on the transfer of air through the air-locks for ventilating purposes, pumps coupled to air-engines would be provided, the energy to work the pumps being obtained from electromotors. To maintain the shaft at a reasonable temperature at the greater depth, powerful means of carrying the heat to the surface would be provided. The most suitable arrangement for cooling would probably consist of large steel pipes, an upcast and a downcast pipe, connected at the top and bottom of each half-mile section in a closed ring. This ring would be filled with brine, which by natural circulation would form a powerful carrier of heat, but the circulation, assisted by electrically-driven centrifugal pumps, would be capable of carrying an enormous quantity of heat upwards to the surface. At each half-mile stage there would be a transfer of the heat from the ring below to the ring above by means of an apparatus similar in construction to a feed-water heater, or to a regenerator constructed of small steel tubes, through which the brine in the ring above would circulate, and around the outside the brine in the ring below could also circulate, the heat being transmitted through the metal of the tubes from brine ring to brine ring.

We have now presented to us two alternative arrangements for cooling. One arrangement would be to cool the brine to a very low temperature in the top ring at the mouth of the shaft by refrigerating machinery, so as to provide a sufficient gradation of temperature in the whole brine system, to ensure the necessary flow of heat upwards from brine ring to brine ring, and overcome all the resistances of heat transfer, and so maintain the lowest ring at the temperature necessary for effectual cooling at the lowest section of the shaft. But a better arrangement would be to place powerful refrigerating machinery at certain of the lower stages, the function of this machinery being to extract heat from the ring below and deliver it to the ring above. This latter method would increase to a very great extent the heat-carrying power of the system, which in the first arrangement is limited by the freezing temperature of brine in the descending column and the highest temperature admissible in the ascending brine column. The amount of heat conducted inwards through the rock-wall and requiring to be absorbed and transferred to the surface depends upon the temperature and conductibility of the strata. But there is no doubt that the methods I have indicated would be capable of maintaining a moderate temperature in the shaft to depths of 12 miles.

During the process of sinking at the greater depths the shaft bottom would require the application of a special cooling process in advance of the sinkers, similar to the Belgian freezing system of M. Poesche used for sinking through water-bearing strata and quicksands, and now in general use. It consists in driving a number of boreholes in a circle outside the perimeter of the shaft to be sunk; through these boreholes very cold brine is circulated, thus freezing the rocks and quicksands and the water therein, and when this process is completed the sinking of the shaft is easily accomplished. In our case this process would be maintained not only on the shaft bottom, but also for some time on the newly-pierced shaft sides, until the surrounding rock had been cooled for some distance from the face. As to the cost, rate of boring, and normal temperature of the rock, an approximate estimate has been made, based on the experience gained on the Rand, but including the extra costs for air-locks and cooling:

	Cost.	Time in years.	Temperature of rock.
For 2 miles depth from the surface ...	£500,000	10	122° F.
,, 4 ,, ,, ,, ...	1,100,000	25	152° F.
,, 6 ,, ,, ,, ...	1,800,000	40	182° F.
,, 8 ,, ,, ,, ...	2,700,000	55	212° F.
,, 10 ,, ,, ,, ...	3,700,000	70	242° F.
,, 12 ,, ,, ,, ...	5,000,000	85	272° F.

I hope I have succeeded in showing in the short time at our disposal that an exploration to great depths is not an impossible undertaking. But my main object in discussing the enterprise at some length has been to show that a pioneer company would not acquire any subsequent monopoly of similar works under the existing patent laws or the laws of any country. In the scheme as I have described it, there appears to be nothing that could be patented; but let us suppose that some good patent could have been found that was absolutely essential to the success of the undertaking, it would certainly have expired before the pioneer company could have reaped any substantial return, and probably before the first enterprise had been completed. It follows, therefore, that at the present time there is no adequate protection, or indeed any protection at all, for the promoters of many great and important pioneer enterprises, some of which might prove of immense benefit to mankind.

Let us ask what change in the laws would place great pioneer research works on a sound financial basis. A Government grant, except for very special purposes, seems to be out of the question, seeing that the benefits to be derived are generally not confined to any one country. An extension of the life of patents, which is now from 14 to 16 years in different countries, would be undoubtedly a step in the right direction. It would be of great benefit generally if some scale of duration of patents could be fixed internationally, the scale being fixed according to the subject matter, the difficulty of the attack, and the past history of the subject, more especially in view of the utility of the invention. One of the chief objections raised by the Privy Council against the extension of patents in this country has rightly been that undue prolongation is unfair to the British public, seeing that abroad no prolongations are granted. Therefore, if the duration of patents for important matters is to be extended at home, it must also be extended abroad. In other words, such prolongations, to be effective, should necessarily extend to other countries. They should be international, and concurrent in all the countries interested. One possible solution of this difficult question would be to place such matters under the jurisdiction of a central international committee, who would have the apportionment of the life and privileges of patents and of the extension or curtailment of their duration, according to their handling by the owners. I would ask, Why has a patent a life of only 14 to 16 years, while copyright is for 42 years? Why has a pioneer company making a railway under Act of Parliament generally rights for ever unless it abuses its privileges, or the requirements of the district necessitate the construction of competing lines, while a patent has in comparison a life of infinite shortness? I might also cite gas companies, electrical supply companies under Act of Parliament or provisional orders of 42 years' duration; and this reminds us of the fact that until the term of life for electric supply companies had been extended from 21 years to 42 years by the Bill of 1884, it was impossible to find capital for such undertakings.

Now, it may be urged that the grant of a patent is a different thing from the grant of power to a railway company, a gas or electric supply company. But the object of this address has been to show that a patent, to be fair to the patentee, ought in many cases to be analogous to an Act of Parliament or a provisional order. Would it not place matters in a fairer position, especially in the case of expensive and lengthy researches, to grant to those who pledge themselves to spend a suitable and minimum sum within a stated period on the research a reasonable and

Digitized by Google

fair monopoly, so that such person or syndicate might in the event of success be in the position to reap a reasonable return for their expenditure and risk? Some such measure would unquestionably give an immense stimulus to research and invention by enabling capital to be raised and works started on commercial lines in fields of great promise at present almost untouched.

I pass over the disadvantages to the British inventor of the hostile patent tariffs of Continental nations, and of the protective patent laws of some of the British dependencies, disadvantages greater than those imposed by protective tariffs on the ordinary British manufacturer. There is, however, another aspect of the question to which I would briefly allude; it is the great benefits that the world at large has derived from the work of inventors in the past. Think of the multitude and power of the great steam-engines and gas-engines that drive our factories, and pump the water out of our mines, and supply our cities with water, light, and power; of the great steamships scattered over the ocean, and the locomotives on the railways. Think of the billions of tons of steel that have been made by the Bessemer, Siemens-Martin, and Thomas Gilchrist processes, and of the great superiority and less cost of the material over the puddled iron which it superseded. Think of the vast work performed by the electric telegraphs and telephones, and we must not fail to include the great chemical and metallurgical processes carried on all over the world, besides the countless other inventions and labour-saving appliances. Can we form any idea of the commercial value of all these gigantic tools that past inventors have left as a heritage to the human race, and can we venture to place any order of magnitude on so vast a sum?

If we take as our unit of value the whole of the money spent on all inventions, both successful and unsuccessful, I think we shall be much below the mark if we assume that the value of the benefits have on the average exceeded by ten-thousandfold the money spent on making and introducing the inventions. If this is so, let us see what it means. It means that for every unit of capital spent by the inventors and their friends on invention, they have in some cases received nothing back. In some cases they have just got their capital back, in some cases two or threefold, occasionally tenfold, very rarely a hundredfold. Whereas the world at large has received a present of ten-thousandfold greater value than all the money spent and mis-spent by the small band of past inventors.

In conclusion, let us hope that the inventor will in the future receive more encouragement and support, that the patent laws will be further modified and extended, that the people at large will consider these matters more closely, and recognise that they are of first importance to their progress and welfare, and that in the future it may be easier, nay in some cases possible, to carry on many great researches into the secrets of Nature.

Address to Section A.

In his address to the mathematical and physical division of the association at Cambridge, Prof. HORACE LAMB, the sectional president, remarked that of the various subjects which fall within the scope of this section there was no difficulty in naming that which at the present time excites the widest interest. The phenomena of radioactivity, ionisation of gases, and so on were not only startling and sensational in themselves, they had suggested most wonderful and far-reaching speculations; and, whatever be the future of these particular theories, they were bound in any case deeply to influence our views on fundamental points of chemistry and physics. No reference to this subject would be, he thought, satisfactory without a word of homage to the unsurpassed patience and skill in the devising of new experimental methods to meet new and subtle conditions which it had evoked. It was felt as a matter of legitimate pride to many present that the University of Cambridge had been so conspicuously associated with this work.

Commenting upon the modern tendency in science, Prof. Lamb observed that one significant result of the modern tendency was that we no longer with the same obstinacy demanded a mechanical explanation of the phenomena of light and electricity, especially since it had been made clear that if one mechanical explanation were possible, there would be an infinity of others. Some minds, indeed, revelling in their new-found freedom, had attempted to disestablish ordinary or "vulgar" matter altogether. He referred to a certain treatise which, by some accident, did not bear its proper title of "Æther and *no* Matter," and to the elaborate investigations of Prof. Osborne Reynolds, which presented the same peculiarity, although the basis was different. Speculations of that nature had, however, been so recently and, he might add, so brilliantly dealt with by Prof. Poynting before that section, that there was little excuse for dwelling further on them now. He would only advert to the question whether, as some suggest, physical science should definitely abandon the attempt to construct mechanical theories in the older sense. The question would appear to be very similar to this, whether we should abandon the use of graphical methods in analysis. In either case we ran the risk of introducing extraneous elements, possibly of a misleading character; but the gain in vividness of perception and in suggestiveness was so great, that we were not likely altogether to forego it, by excess of prudence, in one case more than the other.

WIRELESS TELEGRAPHY.

BY R. G. BLAINE, M.E., A.M.I.C.E., ETC.

(*Concluded from page 229.*)

SIGNALLING TO AND FROM MOVING RAILWAY TRAINS.

Mr. T. A. Edison in 1885 invented, or rather perfected, a method of doing this, said to be due to Mr. Willoughby Smith (see Edison and Gilliland English patent No. 7,583 of 1885). He had a large board 8in. wide, covered with tinfoil, placed along the roof of each car. He used static electricity, and to use his own words, "making the electricity jump 35ft., and transforming every running train of cars into a telegraph station accessible to every other telegraph station on the road, as well as to the passengers." "When the train is telegraphed to," he adds, "the message jumps from the ordinary telegraph wire at the side of the track and alights on this board, being conveyed to the apparatus in the train below." The board is well insulated from the carriage by blocks of glass, all the boards, or rather strips of metal, being electrically connected. A wire is connected with this board or condenser, and through the carriage body to the earth. The apparatus required is an induction coil, the secondary wire of which is of very high resistance, and is in the circuit of the grounding wire referred to, in which may be also a telephone of high resistance. In the primary of the induction coil are a local battery and a revolving circuit breaker. The circuit breaker is shunted by a back-point key, which normally short-circuits it and prevents it from affecting the induction coil. A switch is provided which short-circuits the secondary wire of the induction coil when receiving a message and opens it on transmitting one. The ordinary telegraph wires on poles at the side of the line, and earthed at their ends, are used collectively for conveying the signals—they, in fact, form the other surface of the condenser, the metal strips on the carriages being one surface, whilst the air between is the dielectric. In signalling between *trains* the key in one telegraph office upon one train is worked; this causes static impulses at the condenser surface on this train which affect the wires, and these in turn affect the condensing surface on the other train, and cause audible signals in the telephones there. At each signalling station by the side of the line a large metallic condensing surface is provided, a wire running from this condenser surface to the station, where it is earthed through similar apparatus to those in the carriages, or a separate wire may be run from each telegraph wire to the station, where it is connected to one side of a condenser. The ordinary telegraph Morse keys are shunted by condensers, which do not, it is said, interfere with the ordinary telegraph work, at the same time forming constantly closed paths for the induction impulses. The trains and stations were connected inductively with the line wires in "multiple arc," signals being transmitted as

Digitized by Google

described, Morse characters being employed. The system was put in operation first at Staten Island, United States; next on the Chicago, Milwaukee, and St. Paul line, and by October, 1887, also on the Lehigh Valley line. Messages were sent and received perfectly even when the trains ran at speeds of 60 miles an hour, over 400 messages being sent during one run, and the same winter all the snowed-up trains on the latter line were in constant communication. The system soon fell into disuse, as nobody seemed to want it much.

The De Forest Company are, we understand, at present making arrangements to equip the "Twentieth Century, Limited" express on the New York Central Railroad with their apparatus, so that communication may be kept up with "wireless" stations near the line and about 100 miles apart. The same thing is also being tried in Germany, the train aerials being horizontal and occupying a position similar to that of the communication cord on English lines. Experiments on wireless telegraphy to moving trains have also recently been carried out in Canada on the Grand Trunk Railway there by Profs. Rutherford and Barnes, of McGill University. Whether their system is like that of Mr. Edison or on more modern lines, following Marconi and De Forest, we do not know, but, in any case, the matter is not one of great importance, as it was found in the United States, and probably will be found elsewhere, that very few people, even in America, wish to devote themselves to business to such an extent as to require telegraphic communication during a train journey. It would scarcely pay a railway company, on the other hand, to instal such a system unless a considerable number of passengers require the communication.

Wireless Railway Signalling.—Experiments in connection with wireless intercommunication between moving trains, and between trains and fixed stations along or near the line, have been carried out in England with the Marconi system, in America with the De Forest system, in Germany with the Braun-Slaby system, and in Belgium with the Guarini system (Belgian patent, No. 167,023, Nov. 29 1902). These experiments have shown one thing at any rate—viz., that great power is requisite even for comparatively short distances. It takes (on the authority of M. Guarini) an expenditure of no less than 1 h.p. to communicate "wirelessly" with a moving train only six miles distant. The distance of successful wireless signalling depends, with good apparatus, not only on the power supplied, but on the length of aerials used. In the case of moving trains tall aerials are inadmissible, and horizontal aerials have not proved very successful, their rapid displacement in space having apparently a prejudicial effect. It has been proposed to place a special continuous horizontal aerial near the track, influencing this first by the transmitter, and thus allowing it to act on the receiver connected, say, to a horizontal wire laid along the roofs of the carriages. This special wire by the track would involve considerable expense, and it is doubtful if the utility of wireless intercommunication is, in this case, such as to warrant the expense. M. Emile Guarini, assisted by M. Cesar and Lieutenant Poncelet, made some interesting experiments recently on the Belgian State line, using the ordinary telegraph wires and (unlike Edison, who tried the use of these wires in 1886) a true Hertzian-wave system. In addition to the telegraph wires, intermediate wires were employed to communicate with the transmitter and receiver respectively. M. Guarini, in fact, created at a fixed point, say a station, or at a moving point (on a train) an electromagnetic disturbance by using an oscillator. Such a disturbance is readily detected by a coherer or like receiver at the other fixed (or moving) point near the telegraph wires. The latter take up the Hertz-wave disturbances and radiate them after the manner of aerials.

The energy employed in some of these experiments was 40 watts, the aerial at the fixed station consisting of 40 strands of wire 32·8ft. long, communication being successfully maintained through a distance of 10·4 miles. With energy equivalent to only 15 watts and $\frac{1}{10}$in. spark, a good coherer being employed on a car at a distance of $2\frac{1}{2}$ miles, successful telegraphing was accomplished; the aerial on the car being only $6\frac{1}{2}$ft. long, and consisting of an iron tube 4in. in diameter. Signals were successfully transmitted both ways even when the car was 100ft. to 130ft. away from the telegraph wires, but no data are furnished as to what effect the speed of the car, when moving, had on the distance successfully traversed. No disturbance of any sort was observed in any of the telegraph or telephone instruments connected to the wires along the line. This fact is of interest, and agrees with the results obtained by Profs. Slaby, Turpain, and others. In fact, the high-frequency oscillating currents employed in wireless work do not interfere with the ordinary currents of telegraphic work. It was not even necessary in the experiments of M. Guarini to connect one pole of the oscillator to earth, as it was found that a condenser or simple capacity, consisting of a tube laid parallel with the earth, was sufficient.

M. Guarini tried how the rails would do instead of the telegraph wires. With power equal to 100 watts and a sensitive Blondel coherer, signals were successfully sent, but over a very much shorter distance than before. M. Guarini thinks that a cheap and effective block system might be established by using the telegraph wires to communicate with the *engine* of a moving train. What means would have to be adopted, however, to prevent half a dozen different engines from receiving a given message it is difficult to say, but it might be possible to ensure that a given engine (or van) should be able to communicate only with the train immediately preceding or following—possibly the distance itself would ensure this in most cases. M. Guarini thinks that submarine cables might perform a similar function to that of the telegraph wires in the above experiments. Thus without interfering with the ordinary cable business it might be possible to communicate readily with ships within a certain distance of the cables or with certain portions of coast at present remote from ordinary telegraph stations. In fact, without using the enormous amount of energy required for Transatlantic wireless signalling, the cables might be used as intermediaries, the news being radiated both by land and sea by the wireless methods now so common.

Screening—The Effect of Obstacles, Weather, Light, etc.

Captain Jackson, F.R.S., of the British Navy, read a very interesting paper on "Some Phenomena affecting the Transmission of Electric Waves over the Surface of the Sea and Earth" before the Royal Society in May, 1902. This paper gave the results of most important observations respecting the intercepting power of various obstacles. For instance, in regard to various kinds of rock, soft sandstone, shale, etc., hard limestone, and iron ores transmit electric vibrations with completeness represented by the numbers 72, 58, and 32 per cent. respectively. Barometric variations were also studied and their effect on, or, rather, connection with, the distance of signalling. He finds that, contrary to some of Mr. Marconi's statements, an electrical state of the atmosphere *diminishes* the distance to which signals can be transmitted, although in one case such a state momentarily increased the distance *by nearly 50 per cent.* Mist or dust laden air *diminishes* the distance, and a want of synchronism in the oscillatory discharge of the transmitter, when proper syntonic apparatus are not used, causes zones of silence at the receiver. The irregularity of the trains of waves causing interference at different points of their path may account for this. Captain Jackson's results hardly bear out the extremely optimistic views of some experimenters who stated that bad weather and obstacles had no ill-effect on the signals sent out by the wireless system. Mr. Marconi's observations on the effect of day and night are interesting; they are given in a paper read by Mr. Marconi before the Royal Society in June, 1902.

The Effect of Daylight on Wireless Signalling.—It is found that signals transmitted by night carry much farther and better than during the day. Up to 500 miles little difference was detected by Mr. Marconi, but for greater distances the difference became more and more marked as the distance increased. Aerials 12m. high sufficed at night, but, other things being equal, a height of 18·5m. was required by day. Mr. Marconi suggests that the effect may be due to

Digitized by Google

the diselectrification of the transmitting aerial or elevated conductor by daylight, the electrical oscillations being, therefore, prevented from attaining the large amplitude they would attain by night. The effect is probably more noticeable where, as at Poldhu, a very high potential is necessary in the elevated conductors. The true explanation is probably that referred to by Prof. J. J. Thomson and others—viz., that the sun sending out streams of electrons gives rise to what has been termed an "electron fog," which acts on the long-wave impulses of wireless messages much in the same way that an ordinary fog does in the case of light waves. The ionisation of the air in sunlight is the now generally accepted cause of the difficulty experienced in sending messages over long distances by day.

The Effect of Electrical Storms.—The effect of atmospheric electrical conditions were observed by Captain Jackson. The effect of lightning discharges was to make a record in the receiver even when no lightning was visible to the observer at the receiving station. The approach of electrical disturbances is usually denoted by the printing of a few dots at intervals on the receiving tape, the most frequent record being three dots, the first being separated from the other two by a slight interval like the letters "e i" in the Morse code, this record being that of *distant* lightning. There are other irregular signs—often spelling words on the Morse code—probably due to the same cause. These disturbances are most frequent in summer, and also most frequent near high mountains. They are most frequent at night and between 8 and 10 p.m. When they are present, the distance of successful signalling is reduced by 20 to 70 per cent. as compared with that under the most favourable atmospheric conditions. Many electrical disturbances or magnetic storms which give rise to severe earth currents do not affect wireless instruments, as the following letter, referring to the great disturbances to ordinary telegraphy experienced on Oct. 31, 1903, shows: "Marconi Wireless Telegraph Company, Limited, Finch-lane, London, Nov. 3, 1903. Dear Sir,—In reply to your letter of 2nd inst. we beg to inform you that, from all reports to hand at time of writing, the recent electrical disturbance has had no effect whatever on wireless communication. This is only natural, as these disturbances are apparently oscillations of so long a period as to be altogether outside the range of wireless apparatus operated on the Marconi system.—Yours faithfully, ANDREW GRAY (for the Marconi Wireless Telegraph Company, Limited)."

The Difference between Sea and Land.—Ether vibrations of the wave-length used in wireless telegraphy, say 500ft. to 1,000ft., are much more readily transmitted over sea than over land. This seems to be due to the fact that the sea acts as a sort of mirror, reflecting these waves but not allowing them readily to pass through it; whereas the earth does allow them to diffuse themselves through it more readily. Hence over the sea the waves may be bent or diffracted, so as to adapt themselves to the curvature of the earth much more readily than over land. There will be a mountain of water something like 150 miles high between Cornwall and Cape Cod, so that the ether waves conveying Mr. Marconi's recent messages between the two places must have suffered considerable bending or reflection without extinction. In regard to the speed of ether waves, Dr. Fleming gives a very interesting comparison between water, air, and ether waves. A water wave, at the speed of usual ocean waves, would take 100 hours to reach America, a sound wave four hours, and an ether wave about *the one-sixtieth part of a second.* The results of the experiments of Captain Jackson and others may be summed up in a few sentences as follows: (1) Signalling is much more successful over sea than over land. (2) Signalling is much more successful by night than by day. (3) *Intervening* land or mountains reduces the distance of signalling. (4) Particles held in suspension, such as dust, saline, vapour, etc., also reduce the distance. (5) Electrical disturbances act as adverse factors, and give rise to false signals, known as "strays." Some severe electric storms, however, have no effect on wireless apparatus. (6) With certain transmitting apparatus there may be zones of silence due, perhaps, to interference effects.

CONCLUSION.

Of the future of this wonderful system of message transmission with its many modifications, who can predict? Whilst fully alive to its defects, and to the uncertainty as to results, especially over land, which render it a still not very formidable rival to the older cable systems, one cannot but reflect that the rapidity of advance in the last few years warrants the belief in still greater achievements in the near future. The good work already done must not be minimised by reflections as to unaccomplished possibilities. It may be that in a short time the earth shall be girdled with a complete system or systems of stations, so that all nations may thus be linked in a community of interest—let us hope for universal advancement and peace An important message sent out by a powerful station in England or America may then be read, not only on multitudinous ships at sea, but by lonely missionaries in the swamps of Africa, and by trained mountaineers amid the eternal snows of polar climes. Thus the savage and sage alike, though far from the haunts of civilisation, may at any rate *read* the message eternal love, and sojourners may learn from friends at home how each is remembered in the "dear homeland." Thus may all be encouraged by brotherly help to follow the way which leads "upward every day"; and so through the ether, by means of a new wave-length which man has only recently found eyes to see, may the old command receive further fulfilment: "Let there be light."

ASHTON-UNDER-LYNE ELECTRICITY ACCOUNTS.

The accounts of the Ashton-under-Lyne electricity department for the year ended March 25, 1904, show a total expenditure on capital account to that date of £62,756. Appended are abstracts of the revenue account, general balance-sheet, and statement of electricity generated, sold, etc.

REVENUE ACCOUNT.

Dr. Expenditure.	£	s.	d.
Generation of electricity	4,328	11	1
Distribution of electricity	246	5	10
Attending and repairs to public lamps	151	9	8
Rents, rates, and taxes	406	6	7
Management expenses, salaries, etc.	913	19	10

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notices of Meetings, Issues of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had by Order from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	— 6s. 6d.	— 13s. 0d.
Other Places	5s. 6d.	— 10s. 6d.	— 21s. 0d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

Bound Volumes of "THE ELECTRICAL ENGINEER," *containing half-year's copies, bound in Dark-Blue Cloth, Gold Lettered, price 8s. 6d. New Volume, January to June, 1904, now ready.*

FAITH AND THE B.A.

For what our teachers teach, let us be thankful. The one prevailing thought in reading the presidential address of Mr. Balfour at Cambridge is that we must have "faith," unlimited, untiring faith in our teachers when they are expounding or evolving new theories. Every generation has probably had a theory to explain the phenomena of Nature, or if it had no theory or explanation did not worry on the subject—the world moving on just as quickly or as slowly as it always had done. Just now we have a regeneration of an old theory—only the old theory is now explained in a different manner. Once we heard of "mind, no matter," of centres of force, of knots in the ether; once it was held that whatever existed or did not exist, matter and mass were permanent—eternal. The present theory may be given by extracts from Prof. Sir Oliver Lodge's article in the current issue of *Harper*:

"Matter then appears to be composed of positive and negative electricity, and nothing else."

That is the resultant theory—the imagination plays its part, as will be seen from the following:

"Our present view of an atom of matter, therefore, is something like the following: Picture to oneself an individualised mass of positive electricity diffused uniformly over a space as big as an atom—say a sphere of which two hundred million could lie edge to edge in an inch, or such that a million million million million could be crowded tightly together into an apothecary's grain. Then imagine, disseminated throughout this small spherical region, a number of minute specks of negative electricity, all exactly alike, and all flying about vigorously, each of them repelling every other but all attracted and kept in their orbits by the mass of positive electricity in which they are embedded and flying about. In so far as an atom is impenetrable to other atoms, its parts act on the sentinel principle, not on the crowd principle. There are two ways of keeping hostile people out of an open building. One is to fill it with your own supporters; another is to place an armed policeman at every door. The electrons are extremely energetic and forcible, though in bulk mere specks or centres of force. Every speck is exactly like every other, and each is of the size and weight appropriate to the electron. Different atoms—that is, atoms of different kinds of matter—are all believed to be composed in the same sort of way; but if the atoms of a substance are such that each possesses twenty-three times as many electrons as hydrogen has, we call it sodium. If each atom has two hundred times as many as hydrogen, we call it lead or quicksilver. If it has more than that, it begins to be conspicuously radioactive."

That is the gist of the new theory. We take it on trust, having faith in our teachers; but as for understanding it, we don't. It seems simply to be another stretch of the imagination of the mind of science, and leads us simply to ask questions differing little from those that have been asked before. Does the ether exist, or is it merely an effort of the imagination? Science endows it with every property science requires in the formulation of new theories. What causes repulsion; what attraction? Is velocity eternal? What about space? Action at a distance is tabooed, but surely the distances between repellent specks is comparable with the distance between the earth and the sun. Action at a distance is still the prevailing notion. Still, we have faith—great faith. Our teachers can, as they ought to, imagine things inconceivable to ordinary minds. They are experts, and hence we live in the hope that the rough may be made smooth, and the hidden quite

Digitized by Google

plain. Mr. Balfour touches upon these interesting and troublesome subjects with the hand of a master. It is almost impossible to discover that he shines in another sphere and is not one of the select in the house of the experts. Surely the presidential address at Cambridge will afford ample food for thought.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

TELEPHONY AT GLASGOW.

SIR,—Your contributor, "The Writer on Telephony," narrows the controversy on the above subject down to whether it is true or not that the 1897 estimate was made "for the special purpose of showing what *the then existing telephone system* in Glasgow *ought to have cost* the National Telephone Company." "W. O. T." quotes a statement by Mr. Bennett to the effect that the 1897 estimate was made for that special purpose, and he says that he accepts that statement as the truth, the whole truth, and nothing but the truth, and has based on it all that he has written. I do not accept that statement, but the person who most effectively contradicts Mr. Bennett is not I, but Mr. A. R. Bennett himself.

If Mr. Bennett had made an estimate purely for comparative purposes to show what the then existing system ought to have cost, he would properly have made an estimate for a similar system. The then existing system was an overhead single-wire system. The estimate put in by Mr. Bennett was entitled "Estimate for Glasgow municipal exchange," and described a metallic-circuit underground system of an entirely different character from the then existing system. In referring to the estimate in his evidence, Mr. Bennett spoke of it as a working estimate intended to be carried out; stated that it was backed throughout by tenders from responsible contractors; and in describing the various plant and apparatus to be used, he drew as many distinctions as possible between the proposed system and the then existing system. The wire plant was to be different, the switchboards were to be different, and the instruments were to be different. An estimate merely intended to show "what the existing system ought to have cost" could not have been described in these terms.

Further, the evidence of Bailie John Alexander, the convener of the Telephone Committee, showed that the Council had an actual scheme in hand for a telephone system which they contemplated carrying out if a license was secured. Asked what amount the Council contemplated expending, Mr. Alexander said, "We may have to expend £100,000 or £120,000." Bailie Samuel Chisholm, a member of the Telephone Committee, also stated that the Corporation had applied for a license for establishing a telephone service over the whole area, and that the Corporation had estimates showing that the proposed system could be constructed for under £100,000.

No one can read the report of the evidence taken at the Glasgow enquiry of 1897 without coming to the conclusion that the Glasgow Corporation Telephone Committee believed that they were in possession of a definite working estimate for a Glasgow municipal telephone exchange, and were prepared to begin work on that estimate if they secured the license which they had applied for.

Before the 1898 Select Committee Mr. Bennett gave evidence regarding the Glasgow estimate of the previous year. I will quote simply the following questions and answers. I have italicised the more emphatic statements.

Q. You prepared an estimate, did not you, for Glasgow, too?—Yes, sir, I did, last September.

Q. That is in the Blue-book, is it not?—That is in the Blue-book.

Q. And there is nothing to modify the evidence you gave then?—No.

Q. It is no good repeating the evidence you gave before the Glasgow enquiry, because that is referred to us?—Yes, sir; I would like to let the committee to understand, if possible—if I may be permitted to point the matter out—that *the estimate which I prepared for Glasgow was not so much an estimate as a statement of ascertained cost*, because every item in it is covered by a tender from a competent, well-known electrical firm.

Q. Your estimate would have given a service costing about £19 per subscriber—£18. 16s. and something?

Q. Eighteen pounds sixteen shillings and threepence; and that you say now was not based upon mere theory, but upon actual tenders received?—Upon actual tenders received. The town clerk of Glasgow invited tenders from three or four firms representing the class of work done throughout, and of these tenders what was considered the best was selected from each tender, *and the tenderers (the contractors) were given to understand that they might be called upon to execute the work*, and they were all quite prepared to do that, *so that the Glasgow Corporation, if they had been in a position to accept these tenders, would have been placed in possession of a telephone exchange with* 5,000 *lines*, 5,200 *subscribers, for the sum of* £97,000 *odd*, which is about £18. 16s. 3d. per line. Perhaps I may add that the mileage of line provided for in this estimate considerably exceeded the mileage of line owned by the National Telephone Company in Glasgow at that time. They also have something like 5,200 subscribers on their system, so that this estimate represented a greater mileage than the National possesses now for the same city.

Q. Did it represent metallic circuits, too?—Yes, throughout. For many years I have not put in anything but metallic circuits.

Q. Is the National Telephone Company's service there metallic?—Not at present, except between switchrooms.

Q. Does this include every cost of installation, including the cost of taking up roads and laying them down again?—Everything. I have some of the actual tenders here, if you would like me to put them in.

Q. No; I do not think we need go into it in such detail as that. Have you anything you want to add with regard to the evidence you gave with regard to this Glasgow system before the commissioner?—I do not think so, sir. *I am prepared to stand upon it as I gave it then.*

When the license for the Glasgow municipal system was about to be issued, and work on constructing the system about to begin, Mr. Bennett made a fresh report to the Telephone Committee, dated Feb. 23, 1900. The following extracts from this report bear on the statement quoted by "W. O. T":

"I am of opinion that in the first instance a complete exchange for 5,250 metallic circuit lines—viz., 5,000 subscribers within the city and suburbs, 200 in outlying places in the telephone area, together with 50 public telephone offices—should be undertaken. *This number of completed lines exceeds by* 50 *that provided for in my* 1897 *estimate.*"

The report recommends that as regards floor space in exchanges, ultimate capacity of switchboards, size of poles, and number of conduits in the vicinity of the switchrooms, provision should be made for another 5,250 lines. The report then considers in detail changes in prices subsequent to the preparation of the 1897 estimate, and shows how it was expected to neutralise the effect of such increases of price as had taken place.

Two paragraphs in this report are interesting in view of the remark in the statement quoted by "W. O. T.," that the increased cost at Glasgow is partly due to underground distribution:

"I have good reason to anticipate that a better and cheaper method of distribution to subscribers than by the overhead standards provided for in the 1897 estimate, will be found practicable in at least the more crowded parts of the city."

"I am indebted to the Electricity Committee for having brought to my notice the fact that iron conduits now exist in most of the principal streets of the city, which, although now used for electric lighting purposes, will probably be soon in great part disused. These are quite suitable for telephone cables, and by making them, wherever possible, a part of the telephone system, very considerable economies in first cost could be effected."

After noting a possible reduction in the cost of switchboards given in the 1897 estimate, the report continues as follows:

"Allowing for all the facts, *I am strongly of opinion that the* 1897 *estimate still remains substantially correct*, and that 5,250 completed and 1,200 partially-completed metallic circuit lines can be constructed in the best style, and in conformity with the specification which the Post Office have annexed to the Corporation license, *for* £100,000. *The committee may safely assume that the exchange would be got to work for* £19 *per line.*"

This report, *in which the* 1897 *estimate is again set out in full,*

Digitized by Google

was approved and adopted by the committee and subsequently by the Town Council.

I leave it to "W. O. T." to reconcile these statements with that on which he rests his argument.—Yours, etc.,

HERBERT LAWS WEBB.

35, Old Queen-street, S.W., Aug. 15, 1904.

I understand, Sir, that you have submitted a copy of Mr. Webb's letter to Mr. A. R. Bennett for any remarks he may have to make thereon. Mr. Bennett will probably be able to reconcile his statements made at various times; at any rate, I do not see his difficulty in so doing. What I do see is that Mr. Webb is so completely satisfied with his own interpretation of Mr. Bennett's words that, as I said before, he cannot or will not see another perfectly simple and the probably correct interpretation. Once for all, I am not advocating Mr. Bennett. I want the truth. Mr. Bennett says one thing, and I believe it is so; Mr. Webb says it is not so, and I think him incorrect. In ordinary cases it would not be necessary for me to say all my remarks are my own, and there is no collusion with Mr. Bennett or anyone else. Here, then, is my interpretation of what Mr. Bennett has at various times said, restricting for the present my remarks to the quotations made by Mr. Webb and myself. Mr. Bennett, an ardent advocate of municipal telephony—which, by the way, I am not—was engaged by Glasgow. A company had vested interests there. Mr. Bennett asked himself, What ought to have been the cost to the company of the existing equipment? [Just one more aside. You, Sir, have expressly forbidden me to make any detailed comparison in your journal between what has been done in telephony by a company and by a municipality, giving as a reason the two are not working from the same standpoint, and therefore any such comparisons are misleading.] Also what would be the cost to replace the company's equipment by a similar equipment? As I read the statements of Mr. Bennett, he, with the aid of the town clerk of Glasgow, prepared an estimate, or, rather, *ascertained the cost*, in the only practicable way, by actually getting tenders for a similar equipment. The contractors, we are told, were quite prepared to do the work at the amount of their tenders, and the total sum was £97,000 odd, or £18. 16s. 3d. per line. If my interpretation is right, we can go a step farther. So long as the Glasgow committee was satisfied with the equipment similar to that which existed, so long the estimate of cost stood; the tenders were there, the contractors were there. As I read the matter, however, Glasgow was not satisfied, and wanted something different and better, hence the ascertained cost—ascertained by tenders from contractors—went by the board, and something different had to take its place. The something different Glasgow now has; the cost is greater, because what it has is better than what was. Such is my interpretation. I think it quite justified by the reports and utterances of Mr. Bennett, and to me seems the natural development of things telephonic at Glasgow.—W. O. T.

FROM MR. A. R. BENNETT.

Mr. Webb is fighting a bogey of his own creation. Turning to the Blue-book of the Glasgow telephone enquiry, we find in Mr. A. R. Bennett's evidence in chief the following, in reference to his estimate for an exchange of 5,200 completed instruments:

Q. 5,040. In preparing your estimate, had you in view the making of this system of about the same size and extent as the existing system of the National Telephone Company?—*A.* Yes, it was considered.

Q. 5,041. With a view to comparison?—*A.* Yes.

Q. 5,043. Was it also desirable to verify the estimate by obtaining tenders from responsible firms for the execution of all the most important parts of the work?—*A.* Yes, and such tenders have been obtained for practically the whole of them.

Turning to Mr. Bennett's cross-examination, we find the following:

Q. 5,356. Is it part of your scheme that there should be that number of subscribers in Glasgow?—*A.* In the event of the Corporation proceeding with the scheme, should they honour me by asking my advice, I should recommend an exchange of at least 20,000 to 25,000 subscribers.

Q. 5,359. You seem to be suggesting to the Corporation to set up a new and complete system for the citizens of Glasgow as a whole with a 5,000-line switchboard, because your system is for a 5,000-line switchboard; why do you do that if Glasgow and Stockholm are in the same position, and there is the same necessity for telephone communication per head of population in Glasgow as in Stockholm?—*A.* I think I made it clear in my evidence in chief that the estimate which I have prepared was designedly founded on a similar number of subscribers as exists at present in Glasgow, for the specific purpose of ascertaining the approximate cost of such a system as exists here. That was the object, and it was never proposed that, in the event of the scheme being given effect to, the lines should be allowed for such a small number of subscribers as 5,000 or 6,000.

Q. 5,360. That was never contemplated; suppose the Corporation got a license, how many lines do you contemplate that the scheme should be set a-going with?—*A.* I have no right to speak for the Corporation, but I should recommend them to lay out an exchange for 20,000 or 25,000.

Turning to the summing-up speeches, we find Mr. Salvesen, Q.C., counsel for the Corporation, said: "Mr. Bennett has prepared a most careful estimate as to the constructional cost of a system such as the telephone company are using in Glasgow to-day, to supply the same number of subscribers, and of the working expenses of such a system. There was a great deal of criticism upon his estimate, as not being a scheme which an independent man looking into the future would employ. He did not prepare it with that object. He said that if he were honoured by the city to perfect it, he would lay it out for 20,000 or 25,000 instead of 5,000 subscribers, but the estimate was the only way in which he could compare the system of the National Company with the system that he could at this moment construct within the same area, and which would supply exactly the same number of subscribers."

Mr. Bennett's evidence was supported by tenders from responsible firms, which showed that the scheme for 5,250 lines could be carried out for the estimated amount. Mr. Webb's statement that Bennett spoke of the estimate as being intended to be carried out is, therefore, incorrect. What Bennett did say was, that it was a working estimate that *could* be carried out *if deemed expedient*, and from this he has never swerved. The comparison, with the National Telephone Company, and especially the tenders from firms of good standing, were rendered necessary by the assertion of the company that their exchange, which in round numbers contained some 5,000 lines, had cost four or five times the amount which Mr. Bennett estimated was the proper expenditure for an exchange of that kind. So that Mr. Bennett's subsequent evidence before the Select Committee was entirely correct, that had the Corporation decided to construct an exchange of 5,250 lines, they could have got it for the sum of £97,000. When the license was obtained Mr. Bennett still recommended that these numbers should be adhered to as regards the lines to be completed out of hand, but he also recommended that immediate provision as regards floor space at the exchanges, ultimate capacity of switchboards, etc, should be made for another 5,250 lines, making provision for 11,000 lines in all. This the Telephone Committee agreed to, but subsequently, owing to the unexpectedly liberal manner in which the undertaking was being patronised by the public, and also to the grumbling occasioned by the extensive opening of streets, which made them determined to prevent reopening for a good many years to come, issued instructions for the laying of a very much more extensive scheme.

We are informed that the electric light conduits referred to by Mr. Webb were not brought into use for telephone purposes, except for a distance of a few yards only in two or three localities.

Turning to the detailed estimate printed at the end of the Glasgow Blue-book, it will be noticed that the estimate provides for overhead junction routes to the suburbs, and also for the distribution overhead of the subscribers' spurs. As a matter of fact, the committee issued instructions that all subscribers' spurs should be underground in the centre of the city as well as in the residential suburb of Pollokshields, and that all junction routes to the suburbs should be underground. This order rendered adhesion to the original estimate impossible. The distribution underground in the centre of the city proved to be very expensive, not so much from the actual electrical work, but from the stringent regulations which were made by architects and property agents as to the leading in of underground cables to their premises, and the casing in of the leads in the

Digitized by Google

buildings, almost every architect insisting on a different design of casing.

To sum up, we contend that, allowing for the altered circumstances, and the extensive nature of the spare plant provided, Mr. Bennett's estimate has worked out with a remarkable degree of accuracy, and that although Mr. Webb's criticisms when read by themselves may appear damaging to those whose knowledge of the circumstances is but slender, they entirely lose their force as soon as they come to be dissected in the light of recorded evidence.

[We sent proofs of Mr. Webb's letter to "W. O. T." and to Mr. A. R. Bennett, as we feel strongly that this question of *bonâ fides* should be settled once and for all. The annexed replies of these gentlemen are wholly independent. Once get this bogey estimate accepted or rejected, the discussion is on a different plane, and may prove exceedingly useful and interesting It is a legitimate point for discussion, whether the system adopted as a whole is good or bad, or whether this and that detail is good or bad —ED *E. E.*]

"THE OLD 'UN'S ADVICE"

SIR,—I should like to express my appreciation of "M. M.'s" kindly approbation of my letters, and to assure him that I am entirely in accord with him in eschewing all unnecessary—*i.e.*, avoidable—work. This is only, however, because I have in the course of a varied experience laboured so hard that a little variety is pleasing. On the general principle of not putting my trust in princes, my faith in "influence" is weak—but if a prince passes my way I take care to pull off my hat. If he drops a sixpence therein, so much the better.

I am unprepared to say whether theory or practice is better. I am of opinion that it entirely depends on the temperament of each man considered. Some are practical men by nature, others theoretical. The safe rule for any man is first to get a lot of both theory and practice, and then follow his instincts.

My advice to the Young 'Un appearing this week will show how fully I am in sympathy with "M. M." on the subject of "talking."—Yours, etc., THE OLD' UN.

LETTERS FROM AN OLD HAND TO A YOUNG ONE.

IV.—ON THE USE OF THE JAW.

My Dear Young 'Un,—Your last letter contains remarks which I do not know whether to class as slothful or sly. You say, "It seems to me that working . . . is one of the ways not likely to recompense 'a young one,'" and again, " . . . throw work, like physic, to the dogs, . . . learn not so much how to *do* things as to *talk* about doing them."

Now, if a man starts talking round his hat about things he doesn't understand—particularly practical matters—he will quickly be written down an ass. Therefore, it is no good trying to squirm out of the sweaty part of the business. If you begin trying to cut corners that way, you will find yourself up some blind alley or other.

At the same time, a judicious use of the jaw will probably make the difference between success and failure to you My advice is to Advertise with a big A. You must be your own automobile—get hold of yourself, and push. If a man does a smart bit of work and then gazes dumbly up at his employer's face with an expression of trusting affection, that employer will probably regard him as an intelligent and well-trained bow-wow, and will treat him as such. If, on the other hand, he beards the employer in his den, informs him that the job is done, that it was finished in six hours under the previous record, and that certain new and unexpected obstacles had been made skittles of, the employer will begin to wonder what sort of a rise he must give in order to keep the man.

The tongue is a little member, and it is worth its keep. Only it must be kept in order. It is no good advertising as the pig advertises its shearing—much cry and little wool. Always be sure you are booming a good line, that you have got plenty of stuff for sale, and a reserve fund to cover bad debts. You can learn a lot by studying the advertisement pages of a journal. You will notice, in the first place, that a manufacturer must get into touch with his market. It is no use advertising an alternator in the *Drapers' Record*. In the same way you need not write for a job as a senior draughtsman when your experience has been exclusively mains laying. If you are disappointed, it does not mean that you are no good, but that you are in the wrong market.

Again, it is not enough nowadays merely to advertise that "Buzzem's Motors are The Best." Even a Town Councillor wants a better reason for the faith that is in him than the bold assertion of an interested party. So Mr. Buzzem goes to the trouble of printing a list of installations which use his motors, and of stating the items of excellence—cheapness, reliability, or what not—of his wares. Probably he adorns the tale with a photogravure of his motor and prints the lot on art paper. All of which is a lesson. It is not sufficient to tell people you are clever and want a chance to show it. They want proofs. If you have had previous experience at the job you are on, tell your foreman so, and give him enough particulars to make him believe in your gumption. (As a general rule, avoid jealousy by limiting such information to your *foreman.*) Work up a character for certain definite virtues—punctuality, accuracy, alertness—something good that can be summed up in a word. If ever you get an opportunity for a *tour de force*, use it. It is the illustration to your advertisement And don't forget the art paper. Always be a gentleman. A rough surface spoils a good impression, both in printing and in life.

An advertisement is no good unless it appeals to a want. This weather an enterprising fan motor maker would advertise, "Are you hot? Use Buzzem's fans!" The requirement, coolness; the remedy, Buzzem's fans; the result, worldly prosperity for Mr. Buzzem. In the same way, you have an idea. Wait till it's wanted. When circumstances point to a hitch in the existing arrangements, romp in with your suggestion and reap the *kudos*. Only be careful not to offend the chief's *amour propre*.

Many a man spoils himself by bad expression. I had to read a batch of replies to an advertisement for an engine-driver, and the letters would have made an angel weep (supposing that being so reduced in circumstances as to run an electric light station) The man who got the job had filled his page with a lot of inconsequent rubbish about locomotive driving, crude fitting, sobriety, and general respectability As an afterthought, he stuck in the top left-hand corner, where you generally fix the paper-fastener, "I was driving for eight months at —— electric light station" If I hadn't noticed that before I pinned up the paper, if I hadn't known that at —— they had the same engines as mine, the man would have had no chance. On interview he turned out to be a good man, and since then I have blessed the day I saw him.

When you are asking a man for a job, don't trouble to give your pedigree. Just tell him everything that will make him think you are the best man in the United Kingdom for that particular job, and not a scrap more. If you can schedule your information, so much the better. Carry out the same rule in all your advertising—whether by letter or word of mouth—and you'll do.

To cultivate the gift of expression, join your college engineering society and try to speak. Only don't talk rot. Have a cut at the "Questions and Answers" in the *Electrical Engineer*. Even if you don't win a prize once in a blue moon, you will reap advantage by comparing your replies with the winners!

A final word of warning! When a man begins to talk, the shop shutters are taken down and you can see right in. Many a man has a reputation for wisdom on the strength of a rigid silence. You recollect the yarn of the ass who wanted to make an impression. He togged out in a lion's skin, and for a while all the other beasts were rather nervous of him. But one day he forgot himself, and gloated over the time he was having. And everybody knows a donkey's gloat when he hears it. I could never find out what happened to that moke, but I don't think he lived long.—Yours, THE OLD 'UN.

LONG-DISTANCE SWITCHES.*

One of the chief advantages of electric lighting as compared with other modes of lighting is the simplicity with which it can be operated from any required point. The arrangement is particularly simple and cheap when all the lamps are to be alight at the same time, but it is somewhat more involved when it is necessary to deal with each group of lamps separately, both as regards lighting and extinguishing. If, for instance, the outside lighting of a town had to be controlled direct from the station, this could be done by providing a separate set of mains for these particular lamps. This method, however, becomes too expensive when any great area has to be dealt with, and in such cases the lamps would have to be connected to the ordinary supply mains. This necessitates additional labour, and many attempts have been made to avoid this by means of automatic devices. Clockwork has often been employed to open the circuit at a particular time and close it again after a certain lapse of time. E. Ruhmer has constructed an arrangement consisting of a selenium cell actuated by the daylight and working a relay, which in turn works an automatic switch for opening and closing the circuit.

It is proposed in this article to consider the construction of certain long-distance switches which can either be operated by hand or by one of the above-described automatic methods. These switches may be divided into three classes: (1) those in which the actuating coil carries current continuously; (2) those magnetically locked; (3) those mechanically locked.

Those belonging to group 1 are generally very simple in construction, but the fact that they carry current continuously renders them expensive, especially in the case of the larger switches, even neglecting the current consumption. With groups 2 and 3 the power consumption is extremely small, as the coils are only in circuit at the instant of switching on or off.

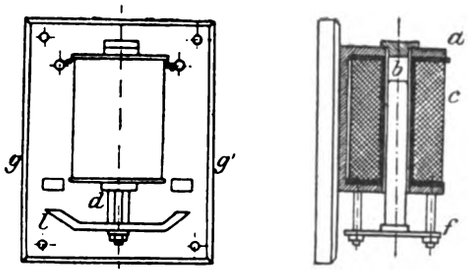

FIG. 1.

1. *Long Distance Switches whose coils carry current continuously.*—Fig. 1 shows a simple type of switch. *a* is a U-shaped piece of sheet iron which carries the exciting coil, *c*, wound on a brass tube, *b*. The contact brush, *l*, is fixed to the core, *d*. *l* is prevented from falling too low by the stops, *f*. *g* and *g'* are the terminals of the circuit to be closed. The whole is mounted on a marble or slate base, and, when placed in the open, is covered by a watertight case. Fig. 2 shows the diagram of connections of this apparatus. The arrangement shown in Fig. 3 is for the purpose of reducing the current round the coil to a minimum as soon as the circuit has been closed. In this way a considerable saving in copper can be effected, since

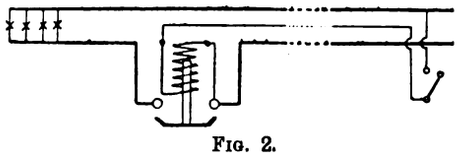

FIG. 2.

the coil may safely be overloaded to 15 times the normal just at the instant of switching on. The action is as follows: As soon as coil *a* receives current through the closing of the switch *u*, the core *b* is drawn right up, the brush *c* makes contact with 1 and 2, whilst, towards the end of the movement, the auxiliary brush *d* leaves the contacts 4 and 5, and so inserts the resistance, *w*, in series with the coil. Since the pull of a magnet varies inversely with the air-gap, the resistance can be so chosen that the current with the resistance inserted is only just sufficient to hold the core up with certainty and produce the necessary pressure at the contacts, *c*.

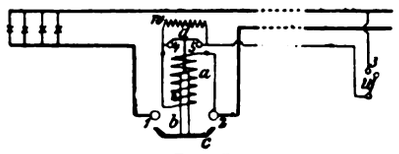

FIG. 3.

A long-distance switch, introduced by Dr. Paul Meyer, of Berlin, is shown diagrammatically in Fig. 4. On this case the actuating current flows through the coil, *a*. The main circuit is closed through mercury contacts. Though these latter are in general beset by a number of difficulties, these are in this case got over in a simple manner. A special glass tube, *c*, through which both the terminals, 1 and 2, project, is partly filled with mercury. The connections with terminals 3 and 4 are made by flexible leads.

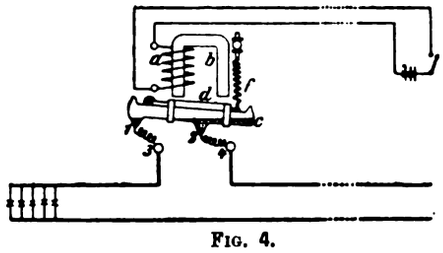

FIG. 4.

The glass tube is carried by the armature, *d*. The spring, *f*, carries part of the weight of armature and tube. When the coil, *a*, is excited the magnet, *b*, attracts the armature, *d*, and the tube, *c*, is brought into the horizontal position, so that the mercury connects contacts 1 and 2. When the current is broken, the armature drops and the mercury opens the circuit.

2. *Magnetically Locked Long-Distance Switches.*—Another type of switch works on the following principle: The exciting coil consists of two windings—a thin one, actuating the switching in and out, and a thick one (main coil), which

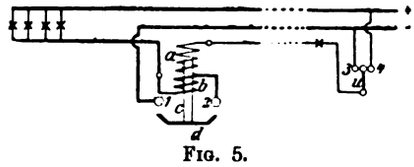

FIG. 5.

serves to hold the switch in the on position. The arrangement is shown in Fig. 5. In order to light the lamps the switch, *w*, is put on to contact 3. A current then flows from the positive pole through the lamps, through windings *b* and *a*, and through contact 3 back to the negative pole. The core, *c*, is attracted and the brush, *d*, closes the circuit. Both ends of *a* are thus connected to the same pole, and *a* carries no current, whilst the supply current flows through *b* in the same direction as on first switching on, and so keeps the switch closed. If the switch, *u*, is moved to contact 4, *a* will receive a current in the opposite direction, and will

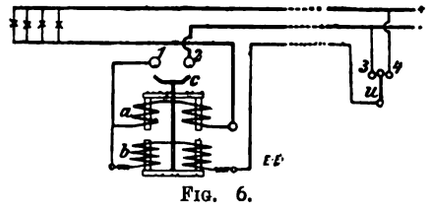

FIG. 6.

oppose *b*, so that *c* falls and opens the contacts 1 and 2. In order to see whether the switch is operating satisfactorily, a lamp can be inserted in the lead connecting the switch, *u*, with the coil, *a*. This lamp will only light up whilst switching in or out. If it burns continuously, it is a proof that the apparatus is not working correctly. Similar indicating devices can be fitted to all the following types of switches.

Fig. 6 shows a switch of similar construction to the last; *a* is a stationary coil carring the main current, whilst *b* is

* Translation of an article in *Elektrotechnische Zeitschrift* for July 28, 1904, by F. Lindenstruth and O. Forster.

Digitized by Google

movable, and carries the contact brush, *c*. The coils are so connected that on switching in poles of opposite sign are opposite one another, whilst on switching out the movable poles become reversed, so that poles of the same sign are opposite to one another.

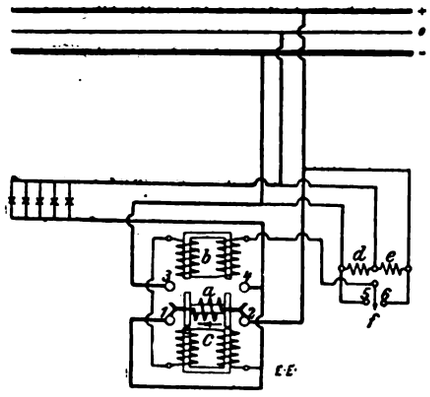

FIG. 7.

The switch shown in Fig. 7 belongs to this class, and works to a certain extent as an automatic balancer on a three-wire system. Unequal loading of the two sides of a system occurs almost exclusively through the lighting, since motors are usually placed across the outers. One or more groups of lamps are therefore connected to the main through the automatic device, and voltage equalisation occurs as follows: The differential relay (voltmeter), *f*, makes contact with either 5 or 6 when any difference in voltage on the two sides exists, and this causes the group of lamps to be connected to either one side or the other of the system. In the diagram it is shown connected between the + pole and the middle wire. When the lamps are not in circuit, *a* is still set in this position. The current flows through *a* in the direction of the arrow and magnetises the hard-steel core. The magnetism of this core passes principally through the core *c* Coils *b* and *c* are only in circuit during the switching operation as they are connected in the same way as those in the two last described cases. Suppose the voltage in the lower side of the system rises, the coil *d* will overpower *e*, and contact 5 will be closed. This excites *b* and *c* in such a way that the *b* cores exert a pull on *a*, whilst *c* pushes *a*. Since *a* has a hard-steel core, this action takes place even when no current is broken; *a* will therefore move towards *b*, and this will cause the change-over to occur at contacts 2 and 3. As soon as the circuit is closed, *b* and *c* carry no current. Should the voltage of the lower side of the system fall to a certain point the operation repeats itself, and the switch is moved to the other side. This switch can also be employed for other purposes, such as the alternate switching in of two separate lighting groups, or as a double-pole arrangement for transferring a group of lamps from one circuit on to a second quite independent circuit.

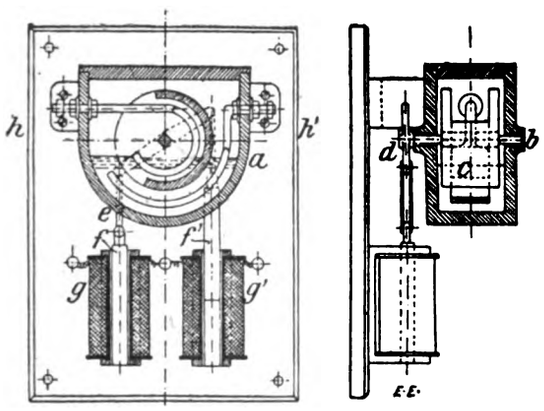

FIG. 8.

3. *Mechanically Locked Long-Distance Switches.*—Fig. 8 shows another switch with mercury contacts. The cylinder, *c*, made of insulating material, is mounted in the insulating holder, *a*, on the spindle, *b*. An extension of *b* carries the arm, *d*, which supports the cores, *f f'*, by means of the rods, *e e*. Both *a* and *c* are filled up to a certain point with mercury, into which the iron terminals, *h h'*, dip. Fig. 9 is the diagram of connections. In order to switch on, the double-pole switch, *u*, is moved to 1; coil *g* then received current through the group of lamps and pulls the core, *f*, thus turning the cylinder, *c*, and bringing the mercury in the latter into contact with that in the outer case, and so closing the circuit. As soon as this happens coil *g* ceases to carry current. In order to switch off, the switch *u* is moved on to contact 2; *g'* receives current and turns the cylinder in the reverse direction, the cylinder wall becomes interposed between the two terminals, the circuit is opened and the current through *g'* is stopped.

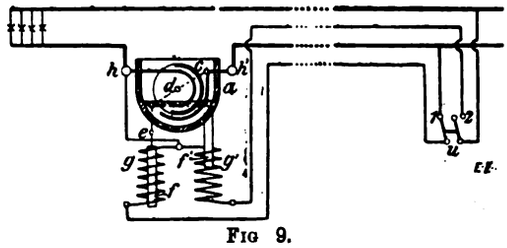

FIG 9.

(To be continued.)

CARDIFF ELECTRICITY WORKS.

The following extracts are taken from the report of Mr. Arthur Ellis, borough electrical engineer, on the working of the Cardiff electricity station for the year ended March 31, 1904.

REVENUE.

Dr. Expenditure.	£	s.	d.
Generation of electricity	6,605	14	2
Energy supplied by tramways department	6,224	14	3
Distribution of electricity	1,057	16	8
Attending and repairs to public lamps	1,003	15	0

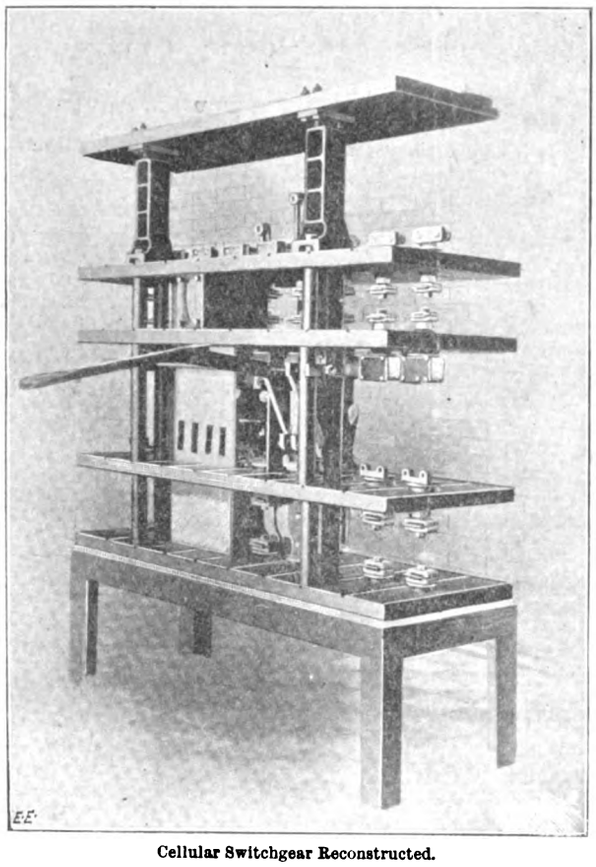
TRADE NOTICES AND NOVELTIES.

A Form of Reconstruction for Cellular Switchgears.

A good deal has recently been written and said concerning the safety of high-tension switchgear, but considering the importance of the subject, it cannot be said that too much attention has been given to it. Bearing on this question, we have some information from Messrs. Walker and Hodgetts, Limited, of Salford, who have set themselves the practical task of demonstrating improvements in the construction of existing high-tension switchgears of the type which has in the past been universally appreciated for use in central stations, particularly upon single-phase systems of 2,000 to 3,000 volts. The improvements consist of some simple detail alterations to the fuses, with several objects in view, amongst which may be mentioned the avoidance of the use of springs, the provision of a new type of flexible conductor inside the pots, and also a mechanical method of fixing the fuse wire in order to replace the existing soldered connections. In the modification of the general construction of the gear, the heavy horizontal slates are taken out of the wall, and the switchgear is reconstructed in the reverse position, so that what has been the back now becomes the front and *vice versâ*. Referring to the accompanying illustration, which represents a trial board, it will be noted that there are four sets of bolts and distance pieces holding the slates together. It is found that a very rigid self-contained switchboard can be obtained in this way, although in actual practice, on a board of the size illustrated, six or eight bolts are used; the bolts are cemented into the distance pieces, and so the construction becomes as solid as if it were mounted into the wall. It will be seen at once that by this means the switches and fuses are removed from the operator. He is shielded from any possible arcing from these by two thicknesses of slate slabs. At first sight it is suggested that this method introduces a back, which has hitherto been absent from the type of gear in question, but on afterthought and inspection it will be found that the objection to a back is practically removed, in that it is possible to see from the station any person at the back through certain portions of the gear. Moreover, the fittings at the back are now shielded in identically the same way as those visible at the front in the original design.



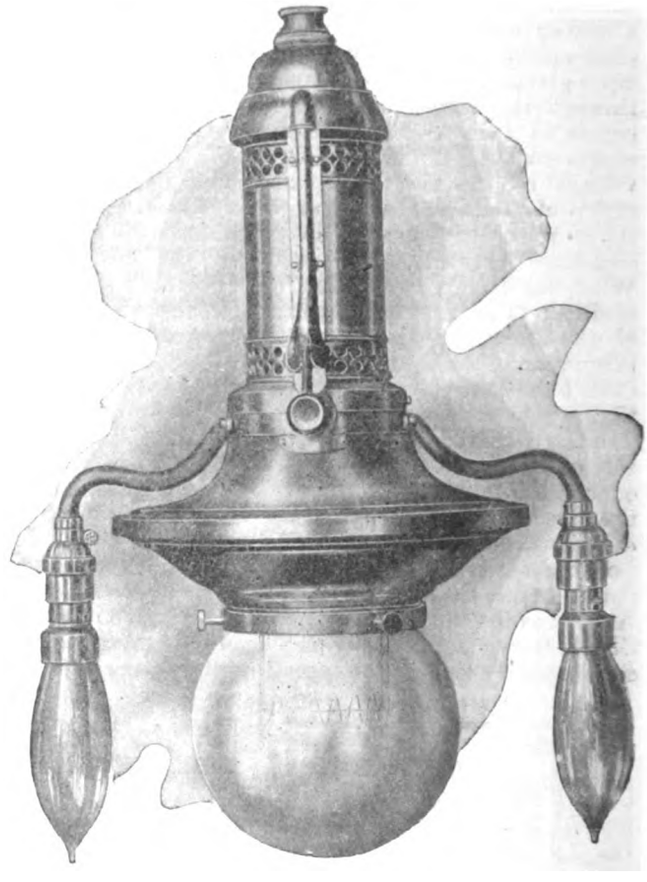
Cellular Switchgear Reconstructed.

Ferranti Alternating-Current Switchboard Integrating Wattmeter.

From Messrs. Ferranti Limited, Hollinwood, Lancashire, we have a catalogue and price-list describing the above. This switchboard integrating wattmeter works on the induction principle, and possesses many distinctive advantages, among which the following are enumerated: (1) the accuracy is independent of variations in power factor, wave form, periodicity, voltage, or temperature; (2) strong mechanical construction; (3) will stand 50 per cent. overload continuously and short-circuit without injury to mechanism or calibration; (4) low starting current; (5) design compact and portable—will stand transit; (6) low shunt current and small losses—highly efficient; (7) will not run on shunt; (8) accurate at all loads, from one-twentieth load to 50 per cent. overload; (9) dial reads direct in Board of Trade units; (10) no brushes, commutator, or moving contacts; (11) low speed of rotation—40 revolutions at full load; (12) light moving parts, reducing wear and friction to a minimum. For currents above 50 amperes and with voltages not exceeding 250 volts, current transformers, Classes A or A A, described in a separate catalogue, are used. These transformers are made in standard sizes up to 6,000 amperes. The wattmeter can therefore be had in standard sizes up 6,000 amperes, for use on circuits of voltages not exceeding 250 volts. On circuits 250-500 volts, and not exceeding 50 amperes, a potential transformer is required, but not a current transformer. On circuits of all currents and voltages exceeding 500 volts, and circuits of currents exceeding 50 amperes, with voltages from 250 to 500 volts, both a potential and a current transformer are required. The potential transformers, dealt with in a third catalogue, are made in standard sizes up to 30,000 volts, and the current transformers in standard sizes up to 2,500 amperes and 30,000 volts.

Nernst Lamps.

The A.E.G. English Manufacturing Company, of 4, New Compton-street, Charing Cross-road, who, as recently stated in these columns, have acquired the English Nernst lamp patents from the A.E.G. of Berlin, have just issued a price list which includes illustrations and particulars of the latest improved types of this lamp. The "Express" type is combined, as shown herewith, with ordinary filament lamps, which serve to give light immediately the current is switched on, thus overcoming the objection to the use of the Nernst lamp in places where instant light is sometimes required. These auxiliary lamps are cut out automatically when the Nernst burner has become conductive. It reflects great credit upon the A.E.G. that all possible objections to the lamp are being so satisfactorily met. The multiple-burner Nernst lamp is also dealt with in the list under notice. It will be remembered that we described this type in a recent issue. The many advantages claimed for these lamps are now so well known as to render repetition unnecessary.



"Express" Type Nernst Lamp.

Revolving Calendar.

The United States Metallic Packing Company, Limited, Bradford, have just issued an excellent little novelty in the form of an aluminium 25-year revolving calendar. The manipulation of this useful article is extremely simple, and the company will supply specimens on application.

A REVIEW OF THE PRESENT STATE OF MECHANICAL CANAL TRACTION.

BY F. H. DAVIES.

The British canal system, consisting, as it does, of some 4,000 miles of waterway, is generally admitted to be one of the finest in the world—that is to say, as far as comprehensiveness goes. Maps of England published a century ago, when the canal as an institution was in its prime, demonstrate this point very forcibly, and show that the majority of towns that may claim to be industrial centres of any importance are linked up by these waterways in a manner that speaks well for the enterprise of our eighteenth-century ancestors. Before the advent of the railway, a great proportion of the carrying trade of this country was in the hands of the canal companies, and dividends that would exceed even the wildest dreams of the present-day investor were, if not the order of the day, of very frequent occurrence. How this is all changed is only too apparent even to the casual observer. In many districts canals that were once flourishing concerns now present only a spectacle of rotting locks and tumbledown banks, perhaps even dry beds, and shares in many enterprises of this nature that once stood at immense premiums may now be purchased for as many pence as they were formerly worth pounds.

The causes of this lamentable decadence are perhaps manifold, but certainly not far to seek. Primarily, the strangulation policy adopted by the railway companies that collectively own over one-fourth of the total mileage is responsible. If canal company shareholders and the public at large have not realised that water carriage of merchandise is commercially possible even in competition with the railways, the latter certainly have, and from the commencement of their existence have systematically adopted a policy of suppression of what they are aware is potentially a dangerous competitor. The apathy of shareholders and directors has in some cases been responsible for the decline in traffic over our waterways. There has been too much bowing to what was apparently deemed the inevitable, and too little enterprise in attempting competition with the railways in the carriage of non-perishable goods, for which canals are so eminently suitable. The argument has always been that existing methods of canal haulage could show little, if any, economy over railway rates, and that what they could would be more than nullified by the slowness of this form of carriage. An increase of speed from an average of 2½ to 4 miles an hour it has been admitted would be of great value in popularising canal traffic, but this speed is commonly deemed prohibitive, owing to the narrowness of most English canals, and the consequent damage to the banks by the wash.

If there is any truth in these objections, it is extraordinary that some railway companies can and do make profit out of the canals that they control while using the old method of horse traction with its speed of 2½ miles an hour. The only solution can be that they charge full railway rates, and the profit—in some cases as much as 100 per cent.—comes from the difference in the cost of the two methods. How much more, then, can this profit be increased by the substitution of mechanical traction for the inefficient horse. The subject has been thoroughly gone into, and the figures are conclusive; the greatest authorities give them as ·077d. per ton-mile for horse haulage at the lowest estimate, and ·032d. per ton-mile with an electric tractor.

These are the extreme examples, the worst and the best, but any mechanical system of traction comes out cheaper than the horse in working costs, although some that have been suggested are scarcely as convenient or reliable, and all necessarily involve a much heavier capital outlay. In the present state of affairs it would, of course, be impossible for the more or less bankrupt canal companies to obtain the capital necessary to place them on a competitive basis with the railways, and in their case State interference of some sort is the only hope. On the other hand, some of the railways, and those canal companies whose trade still warrants it, might very advantageously replace their existing primitive methods of traction by more efficient and economical means, such as are largely employed on the Continent and in America.

The problem of the adaption of such means to the requirements of English canals is interesting, and to a certain extent complicated by the varieties of gauges and general utter lack of standardisation that naturally exists. Taking an average case, the following are the leading requirements that a system must possess to be successful in this country: (1) it must not interfere with the use of horses, as they can only be gradually replaced, and must be of a kind that the ordinary barge can be adapted to with little or no alteration; (2) in the interests of the banks, the means employed must not be productive of a much greater wash than is usual with horse haulage, even at reasonably increased speeds; (3) there must be no waste of time or difficulty in barges passing one another or in going through locks, and the construction must be such as not to introduce difficulties at sharp bends, junctions, or tunnels; (4) no extra labour must be involved, rather it should be possible to decrease the number of hands, and the control of the apparatus must be well within the intelligence of the average bargemaster; (5) the operating expenses must be low, and the construction substantial and easy of repair. Such systems as are in common use or have been proposed may be roughly divided into (1) those where the barge carries its own propelling engine, and (2) those employing haulage by a moving rope or mechanical tractors on the towpath. These again may be sub-divided and examined in detail for the manner in which they come up to the above requirements

Irrespective of the power employed, those of the first class are open to many objections. Gas and oil engines have been installed on barges and used in conjunction with a screw propeller, but not with any very marked success. In the former case gas has to be stored in cylinders in a highly compressed state, which is a great disadvantage, necessitating as it does compressing stations along the line of route. However, this system has apparently been successful in France, where it is used by the Seine Maritime Cie. for their high-speed barge service between Paris and the coast. Oil-engines seem rather more suitable, as the source of power is easier stored, but they would probably take up a great deal of room, which is naturally undesirable where space means money to the extent that it does on a barge. For the same reason steam-engines do not find any great favour, and although self propelled barges of this type are to be met with on many of our waterways, being very costly they cannot be looked upon as a final solution to the problem. Canal propulsion by the aid of accumulators has been tried, and has even found its advocates, although it is difficult to see upon what points they can base their preference. Such a system suffers under most obvious disadvantages: its efficiency is low, capital cost high, repairs high, and recharging operations wasteful of time. If the discharged cells are removed in bulk and replaced by fresh ones in order to avoid the delay consequent upon charging *in situ*, the old difficulties that have been found in accumulator tramway traction arise, complicated by the fact that an ordinary barge does not afford as many conveniences for rapid changing of cells as does a tramcar. Of course, the conditions as regards deterioration of plates by vibration are more favourable, and the absence of repeated starting strains would doubtless enhance the all-round efficiency, but in the present state of accumulator manufacture a system upon such lines would, by reason of its inefficiency, stand but a poor chance in competition with almost any other mechanical means.

All such systems fall foul of the first and most important requirement, that little or no alteration to the barges must be needed. Such installations would involve a comparatively large capital outlay that would be entirely unproductive at times of loading and unloading, and in the present state of canal company finance this a matter of some importance. It has been proposed to make the engines or motors portable, so that upon a barge arriving at the end of its journey the plant could be transferred to another ready to start back, the capital expenditure in motive power being thus reduced to a minimum. Plausible in theory, such an arrangement would scarcely be successful in practice, except, perhaps, in the case of the electric

Digitized by Google

motor, which is much more portable than any steam, gas, or oil engine. With an overhead trolley system, such as has been frequently employed in canal work, it would be possible and economical to arrange things in this manner. The propeller actuated through bevel wheels by a combination of horizontal and vertical shafts, could be fixed either to the extreme end of the rudder or its posts, and worked by a motor temporarily fixed to the deck under the tiller. It would be a simple operation of only a few minutes to change the motor from barge to barge, and the only alteration necessary would be that to the rudder. A similar arrangement to this has been tried in France, with the result that a 180-ton barge, 125ft. long, was propelled at a speed 40 per cent. higher than that attained by two horses, at an expenditure of 3·4 units per hour—a highly satisfactory result.

A trouble with the overhead trolley system is the inevitable delay that must take place when two barges meet. The collecting arrangement must necessarily be of a very different type to the familiar tramcar trolley pole, greater flexibility and length of reach being essential. It follows, then, for these reasons that the difficulties are enhanced, and this is particularly the case where the most suitable form of collecting apparatus for canal work is used—viz, the over-running trolley with a pendulum balance weight. Here, as in the old tramway system, the trolley is pulled along by the barge by aid of the cable that conveys the current to the motor. Of course, the installation of an up and down trolley line gets rid of this difficulty, but at a cost that in some cases might be too great.

The screw-propelled barge suffers under several disadvantages. Firstly, the shape of the vessel is not favourable to efficient screw propulsion. The stern is too blunt, and consequently the state of the water in which the propeller works is not such as to secure high duty. The comparatively small cross-section of the volume of water in the average canal is another source of propeller inefficiency, and on this score the paddle or stern-wheel are preferable for such shallow waters, but, being bulky and expensive, are consequently not in much use. Again, the destructive action of the propeller wash on the banks is a matter of high importance. Even at low speed it has been found that this wash, in conjunction with that caused by the movement of the boat, eats away the banks at an alarming rate.

Then upon the score of economy in capital outlay, it is obviously desirable that only a portion of the barges should be fitted with propelling machinery, such being used as tugs in addition to carrying their own cargo. But mechanically this is not an efficient arrangement by any means, for if the barges are closely coupled together, as they should be in order to reduce the tractive effort, the back wash from the propeller introduces a great resistance to the progression of the towed barge; and if, on the other hand, a long tow-rope is used, the advantages gained by close coupling are lost. Which is the greater loss can only be determined by experiment, but it has been ascertained that the propulsion of a barge by a screw propeller takes approximately double the power that would be absorbed by a tractor on the towpath, and it appears probable that in tugging either with a long or short rope the second barge will absorb an amount equal to the tug, although in the case of a long train the efficiency of the whole would rise rapidly with the number of boats if closely coupled together.

A method of mechanical barge propulsion that appears to have met with a certain measure of success is the Bovet chain-hauling system. Here a chain is laid in the bed of the canal, and the tug barge, fitted with a motor-driven drum round which the chain makes a three-quarter turn, hauls itself along in this manner. Current is taken from an overhead line by means of a trolley, and returns through the chain to earth. Such a system is installed on the Seine between Paris and Rouen, and as far as efficiency goes appears very satisfactory. An ingenious device in connection with this was introduced some years ago by M. De Bovet, engineer to the company. Up to that time ordinary methods of chain haulage had necessitated the taking aboard of large lengths of cable, in order to obtain the necessary amount of adhesion to the driving drum. This was found to be not altogether desirable, and as a consequence the magnetic pulley illustrated in Fig. 1 was introduced, which has the effect of greatly increasing the adhesion of the chain, although only a small length is taken in-board. The pulley is of mild steel, 4ft. in diameter, and is wound internally with a powerful magnetising coil after the style of the Mordey alternator. The periphery is split in a manner suitable to the form of the chain, which, in passing over, completes the magnetic circuit, and therefore adheres very strongly to the pulley face. The ends of the coil are taken to two slip rings mounted on an insulating bush on the shaft. An advantage of this arrangement is that, although increased adhesion is obtained, slip is still possible in cases of emergency, such as the chain fouling. Perfect adhesion could, of course, be ensured by the use of a pulley cut to fit the chain, but this would be at the expense of risk should anything go wrong with the towing arrangements, as is always possible with this system.

It is here that the great disadvantage of chain haulage lies. Two chains must be laid to provide for up and down traffic, the time that would be wasted in passing with only one chain in use being prohibitive. But with two chains trouble frequently arises at curves by their getting entangled, and this may possibly lead to breakages, and at any rate causes delay. From experimental trials of the Bovet system it was found that the hourly current consumption of a 200-ton barge was 3·2 units when moving at a rate of approximately two miles per hour, which result

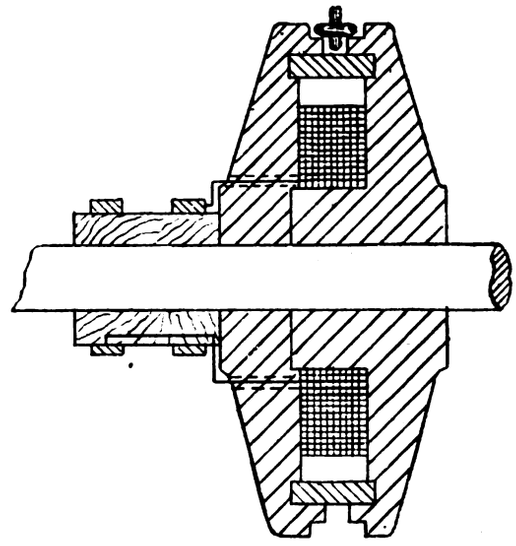

FIG. 1.—Bovet Magnetic Adhesion Chain Pulley.

is about equal to screw propulsion, and a large saving over horses. This system is eminently suitable for tunnels, has the advantage of leaving the towpath free, does not deteriorate the banks, and requires but little alteration to the barges. Its disadvantages, as stated, are chiefly the difficulties met with at bends, and the delay that would be caused by a breakage of the chain.

Turning now to Class 2, we come to some interesting examples, most of which offer economic advantages in running costs over any of the above methods. Canals and barges were originally designed for the propulsion of the latter by haulage from the towpath; and this being the case it is not surprising that such systems give the best results. Self-propulsion of any kind but that due to Bovet requires wider waterways and differently designed barges. Haulage from the banks suits existing conditions perfectly, and the only question is which is the all-round best and most convenient of the systems that have been proposed. The endless rope is the earliest and the worst of them. Its efficiency was very low, and at the best it was only suitable for short distances. The practical difficulties found in its operation were numerous: the rope was apt to break and derange the whole system, difficulty was experienced in attaching the tow-rope to it, and in the passage of the latter by the guide pulleys of the former. Also the starting effort when the rope was attached was very sudden, so much so as to frequently

Digitized by Google

cause fracture of the tow-cable, and always severe strains on the running rope. Seeing all these disadvantages, it is not strange that this system never made much headway; at the present time it is, of course, quite outside the pale of consideration, as so many infinitely better methods are at hand. One of these, the Lamb electrical system, provides a form of aerial railway in the shape of one strong conductor upon which the motor runs, and another slighter one insulated from the former, which acts as the other lead of the circuit. Both cables are suspended upon stout posts, and the latter passes round a wheel driven through worm gearing by the motor, and thus supplies it with current.

The tow-rope is attached to the motor, which can either be controlled from the bank or the barge, in the latter case all that is necessary being a pair of small leads carried along the hauling rope. For light work this system would appear to contain the elements of success. Its operating costs, in common with all electrical methods, would be considerably lower than those of horse haulage, and in capital outlay it should be able to compete easily with any tractor system. It can be worked on a single line, the up and down barges simply changing tractors when they meet, or, if preferred, two separate wires may easily be installed on the same posts, one above the other.

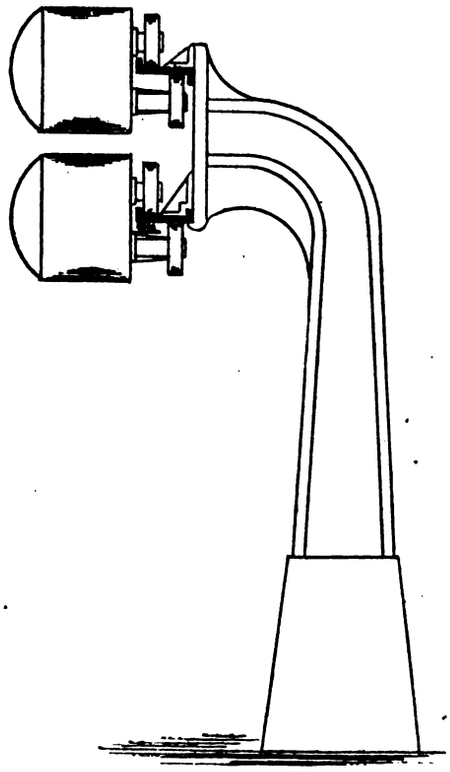

FIG. 2.—Thwaite Canal Haulage System.

Of further examples of tractor systems, the most noteworthy is the Thwaite. An interesting and complete paper was read on this method by Mr. A. H. Allen before the British Association for the Advancement of Science, Bristol, in 1898. In order to leave the towpath free, an aerial rail is used, consisting of two single up and down girder rails fixed from 6ft. to 10ft. high on substantial cast-iron brackets placed a distance of 30ft. or so apart. The details of this arrangement, which are quite unique, are shown in Fig. 2. Each tractor is simply a motor mounted on four wheels, two running on top and two underneath the rail, all four wheels being driven by the motor through worm gearing running in an oil-bath. Lateral movement of the motor is provided for by spring-controlled horizontal rollers pressing against the side of the rail. Mechanically, this arrangement is rigid and very suitable to take up the side pull of the tow-rope, and its adhesion to the rail must obviously be very high. A bare conductor consisting of angle iron or copper strip is carried on insulators fixed to a wooden batten, which in turn is attached to the underneath side of the rail as shown. A collecting brush rubs against this, and the current returns through the wheels to the track in the usual manner. The control of the tractor may be effected in various ways, according to whether the starting switch is fixed to it or placed on the barge. In the latter case a twin cable running along the tow-rope is all that is necessary, and in the former the control may easily be effected by the aid of cords attached to the switch handle. The running cost of this system is given by Mr. Allen as ·032d. per ton-mile at a speed of 2½ miles per hour, and ·041d. at four miles per hour, which figures are inclusive of depreciation, interest, and all revenue charges. The capital cost of the aerial railway is estimated at £1,800 per mile, and the total expenditure for a 30-mile canal, including all generating plant, is given as £77,500 for a low speed of propulsion, while at four miles per hour the above figures are increased to £2,400 and £99,600 respectively. The Thwaite system of haulage would appear to fulfil all the necessary requirements, and, above all, it does not call for any alteration to the existing floating stock.

Other methods of haulage from the towing path generally consist of an electric locomotive running on a narrow-gauge line on the bank, taking current from an overhead wire. Small steam-engines have been tried, but the extra attendance required, higher cost, and necessity of providing coaling stations every few miles, render them incapable of competing with electricity. In America there are several instances of electric barge haulage of this kind, the most conspicuous being the Erie Canal installation of over 60 miles, to be ultimately extended to four times that length in order to link up the towns of Toledo and Cincinnati. Large 24-ton locomotives are used on this system, which is designed for the towing of fleets, not of single barges. High-tension three-phase current is taken from an overhead line, and speed control of the two motors with which each locomotive is fitted is obtained by the well-known concatenation method. The whole length of the line is single track with turn-outs, and convoys being run to schedule time, little delay is experienced in the passing of up and down traffic. This, practically the largest system of electrical barge propulsion in the world, has been fully described in the *Street Railway Review* (U.S.A.), a perusal of which account is worth while to those interested in the problem of electrical canal working upon a large scale. There are many Continental systems in existence based upon much the same lines as the above—that is, a track (generally narrow gauge) on the towpath and electric locomotives supplied with current from an overhead wire. They mostly, however, use direct current, which is more suitable and economical for small or medium-sized work.

An examination of this interesting subject leads to the conclusion that the adaption of mechanical propulsion to English canals would, with practically no exception, be most advantageously carried out by means of electrical tractors, aerial or otherwise. Self-propulsion is not desirable on our narrow waterways, besides which it has been proved to be less efficient, although, of course, more flexible. However, where capital cost is the prime consideration, as in the present unfortunate state of canal matters is generally the case, self-propulsion with transferable motors—despite its disadvantages—would be an improvement in every way upon horses, and, what is most important, would easily lend itself to ultimate conversion into a tractor system, the trolley line being common to both. The barge motors and propelling gear being small and cheap, might be scrapped without very much loss, provided the increased trade and returns that would be sure to follow even a self-propelling system were sufficient to warrant the issue of fresh capital to find the permanent way and tractors.

In these times of tight money we can, unfortunately, expect but little advancement in this hitherto neglected direction. It is absurd, however, to suppose that the fine canal system possessed by this country will always be allowed to remain in its present disused state. Within the last few years the subject has aroused a certain amount of attention, and there appears every probability that a better state of national finances may ultimately lead to the commercial resurrection of our waterways; in view of the heavy freight charges of many of the railway companies, "a consummation devoutly to be desired."

LEGAL INTELLIGENCE.

DAMAGE TO TELEGRAPH INSULATORS.

William Milburn was charged at Consett with damaging telegraph insulators, the property of the Postmaster-General.

It appeared that this youth was observed amusing himself by discharging stones with a catapult at the telegraph insulators near the Co-operative Stores, Leadgate. A representative of the Post Office said that within the last six months between 30 and 40 insulators had been broken in the neighbourhood.

Defendant was fined 5s. and costs.

DAMAGES FOR FATAL ACCIDENT.

At Glamorgan Assizes the action of Lily Emily Williams, spinster, against the Corporation of Cardiff for £300 damages for the loss of her father by the negligence of the defendants was heard.

It appeared that the deceased was walking along the street with his back to an advancing car. This overtook him, knocked him down, and dragged him along for some 25 yards before the car was brought to a stop. The contention was that the car must have been travelling at an excessive speed to take such a distance before coming to a standstill. Ten miles an hour is the authorised speed of the Cardiff trams. The Corporation did not plead contributory negligence.

Evidence in support of the claim having been given, counsel for the defence called evidence to prove that ample warning was given by the gong.

Finally, the jury returned a verdict for the plaintiff, awarding her £75.

COMPANIES' MEETINGS AND REPORTS

ELECTRO-PEAT COAL.

The statutory meeting of the shareholders in the Electro-Peat Coal Company, Limited, was held at the Westminster Palace Hotel, London, the Earl of Mayo (the chairman) presiding. The Press were excluded from the meeting, but the following are extracts from the official report:

The **Chairman**, alluding to criticisms which had appeared in the Press, stated that he wished to reassure the shareholders in regard to the patent. The Board would not have thought of spending the shareholders' money until they had made certain that the patent was all right. Mr. Fletcher Moulton's opinion was that the English patent should stand, but that a further claim might be lodged, following the lines of the patent recently accepted by the German Patent Office. This brought him to another important point, which was that the syndicate had sold the German patent, and that, as he understood, the purchasers had already made a cash deposit and ordered machinery from Messrs. Johnson and Phillips to start manufacturing.

Mr. Scoones, M.I C.E., then gave an explanation in regard to the calorific power of electro-peat coal. He stated that he was not aware until after the issue of the prospectus that the expression "British thermal units" referred to kilogrammes, not pounds. He then went more fully into the subject, and found that it was wrong to compare dry coal with peat holding a percentage of moisture, and that it is necessary to allow for the moisture in order to compare the two. Mr. Scoones proceeded to deal at some length with the figures given by the respective analysts, which, he maintained, fully justified the accuracy of his report. Continuing, he said: Practically, we may say with some certainty that electro-peat coal has a calorific value of about 13,000. It has been said in the papers, and it was incidentally mentioned just now, that there is a comparison with coal in the matter of calores in my report. There is nothing of the kind. There is not one word of comparison in this report, as it was necessary to come to a more practical conclusion than is given by the amount of calores, which has little to do with its practical value as fuel. In Lancashire coal—and I am quoting now from Messrs. Crace, Calvert, and Thomson's analysis, Royal Institution Laboratory, Manchester—that amount to 12,600 British thermal units, while Scotch coal varies from 7,480 to about 7,810. I think those of us who are engaged in enterprises know that the Scotchmen are not very much out of it when they come to tender. If they can carry on great industries with coal at 8,000 British thermal units, I think we are not put to any disadvantage with our electro-peat coal, which, on the lowest analysis made, comes out considerably above this figure. The only use of calores is primarily to ascertain whether, as a fuel, it has certain calorific value in order to make comparisons, in the elementary stage, with peat, wood, coal, or other fuel.

After some discussion, the proceedings terminated with a vote of thanks to the chairman for presiding.

KALGOORLIE ELECTRIC POWER AND LIGHTING.

The report of the Kalgoorlie Electric Power and Lighting Corporation, Limited, for 1903, to be submitted at the meeting on the 23rd inst., states that there has been a steady and increasing demand for power. Most of the small mines in existence when the supply from a central station was in contemplation have either closed down entirely or suspended operations, but negotiations are proceeding with some of the large mines now in operation for the sale of the power remaining at the disposal of the Company. A profit of £9,336 was earned on the other side after charging all costs of production, maintenance, and other expenses to keep the plant running in a high state of efficiency. Out of this amount, after providing for debenture interest and London charges, the directors have set aside £1,000 to reserve, written off the whole cost of issue of debentures (£2,525), and reduced the amount standing to debit of preliminary expenses by £1,063. The sum of £5,091 has been added to capital account during the year and £6,527 expended on transmission lines. Since the date of the last report 8 000ft. of new pole lines have been constructed, and some 190,250ft. of transmission wire erected, making a total at the end of April of about 35,000ft. of pole lines and 286,850ft. of overhead cable erected. Since the date to which the accounts are made up, £2,982 has been received on account of calls, reducing the amount now owing to £1,949; £7,615 has been paid off the bank overdraft, which now stands at £1,134, and off the item of bills payable £3,411 has been paid, reducing the amount now owing to £1,489. The power sales for the current year up to the date of the last return show an increase of 95 per cent. over the corresponding period of 1903.

WATERLOO AND CITY RAILWAY.

The half-yearly meeting of the Waterloo and City Railway Company was held on the 12th inst., Sir Charles Scotter presiding. Particulars of the report appeared in our issue of the 5th inst.

The **Chairman** stated that during the six months under review there had been a falling off in the number of passengers carried of 53,783, but this was more than compensated for by the increase of the number of season-ticket holders, who numbered 1,611, as compared with 1,244 in the corresponding half of last year. The number of daily journeys represented by the season tickets worked out at 502,632, as against 388,198 in the first half of 1903. That showed the large increase of 114,504, so that the apparent decrease of more than 50,000 persons turned out to be a net increase of about 60,000. In money there was a small decrease of £147, but this was accounted for by the fact that the daily fares—2d. single and 3d. return—were worth more to the Company than the season-ticket rates. Their line was not exceptional in this respect. The Central London Railway, for instance, showed a decrease of 209,000 in passengers and £2,008 in money. During the recent period of hot weather the passenger returns showed a distinct falling off. This was remarkable, for it was a fact that the "tube" during these hot weeks had been the coolest place in London. Their working expenses for the half-year worked out at 47·55, and showed that they were working at a cheaper rate than the South London Railway or the Central London Railway. A year ago their working expenses were 46 per cent., and but for an accident to a passenger their working expenses would have shown no increase.

The report was adopted.

LIVERPOOL OVERHEAD RAILWAY.

The half-yearly meeting was held at Liverpool, Sir William B. Forwood presiding.

In moving the adoption of the report (which appeared in our issue of the 5th inst.), the **Chairman** remarked that the Company perhaps felt slackness of trade more than any other railway, because they were dependent entirely on the movement of passengers in connection with the trade of the port. They had also suffered from a considerable diminution in holiday traffic. About two-thirds of the line had been relaid, and they hoped to complete that work by the end of the year. They had concluded an agreement with the Lancashire and Yorkshire Railway Company, and had let the contract for making a physical connection with that line at Seaforth. Under the terms of the contract the work ought to be completed by next February, when they hoped to be running a through service to Southport in connection with the Lancashire and Yorkshire Railway.

Sir Edward Lawrence seconded the motion, which was adopted.

TYNESIDE TRAMWAYS.

The half-yearly meeting of this Company was held at the Station Hotel, Newcastle, on Tuesday, Lord Armstrong presiding.

The report showed that the receipts, which are steadily increasing, exceeded the expenditure by £1,454, which, with the balance brought forward from the previous half-year, gave a total balance of £1,533. Out of this it was proposed to pay a dividend at the rate of 2 per cent. per annum.

The **Chairman**, alluding to the inter-running question, predicted that the agreement entered into with the Newcastle Corporation would secure a material increase of revenue to both parties. The directors had received by private subscriptions £7,500 of the authorised issue of £60,000 previously approved, but did not issue the debentures until the running powers dispute was over. The issue would now be made at an early date at 5 per cent., redeemable at par in 10 years. They had still unissued authorised share capital to the amount of £80,000.

Mr. Merz seconded the resolution, and the report was adopted.

In moving a vote of thanks to the chairman, **Alderman Boyd** (Wallsend) urged the need of a liberal depreciation fund, so as to build up a strong reserve.

Dr. R. Spence Watson, in seconding the vote, commented on the happy issue of the running powers controversy.

Lord Armstrong, in reply, said the directors would consider the question of depreciation on a liberal scale before the annual meeting. The question of providing a reliable time-table would not be overlooked.

GREAT NORTHERN AND CITY RAILWAY.

The twelfth half-yearly general meeting of the Great Northern and City Railway Company was held at the Westminster Palace Hotel under the presidency of Sir Charles Scotter, chairman of the Company.

We published particulars of the report last week.

Digitized by Google

The **Chairman**, in moving the adoption of the report, announced that the difficulties with the Great Northern Railway had been settled, and that on Monday next a working arrangement between the two concerns would come into operation. In reply to a question, he stated that the question of extending the system would be considered by the directors when financial conditions were more favourable.

The **Earl of Lauderdale** (deputy-chairman) seconded the motion, which was carried unanimously.

Sir Charles Scotter has resigned his position on the Board consequent upon his appointment to the chairmanship of the London and South-Western Railway.

NEW COMPANIES REGISTERED.

West-end Motor Company, Limited (81,789).—Capital, £3,000. Objects: to acquire and carry on the business of A. S. Ross, at 61 and 62, High-street, Bloomsbury, and 83, Hatton-garden, E.C., as the West-end Motor Company, as manufacturers of and dealers in motor-propelled cycles, carriages, omnibuses, machines, and horseless vehicles of every description.

British Meeline Company, Limited. — Capital, £50,000. Objects: to carry on the business of mechanical, electrical, and general engineers, etc. Registered office: Tokenhouse-buildings, King's Arms-yard, E.C.

Chamberlains, Limited (81,744).—Capital, £1,500. Objects: to acquire the business carried on at 149, Gray's-inn-road, London, as Chamberlains, to adopt an agreement with H. P. Clarke and H. Platts, and to carry on in the United Kingdom or elsewhere the business of specialists in gas, electric, and other methods of lighting, heating, and ventilating apparatus and appliances, manufacturers of and dealers in incandescent fittings, mantles, and accessories, etc.

Printers' Engineers, Limited (81,737). — Capital, £40,000. Objects: to carry on the business of printers' machinery manufacturers, mechanical engineers, machinists, electrical engineers, etc.

Generators, Limited.—Capital, £5,000. Object: to acquire the business carried on at 77-78, Trevelyan-buildings, 52, Corporation-street, and elsewhere in Manchester, by J. M. Wallwin, as generators, to adopt an agreement with the said vendor, and to carry on the business of electrical and mechanical engineers, electricians, manufacturers, workers, and dealers in electricity, motive power, and light, generator manufacturers. etc. Registered office: 77-78, Trevelyan-buildings, 52, Corporation-street, Manchester.

Liens Registered.

Guildford Electricity Supply Company, Limited. — Lien registered July 26 for £1,600 6 per cent. debentures (renewals), part of £15,000 issued; no trustees; charged on the undertaking and all the property, present and future, including the uncalled capital.

Yorkshire Electric Tramways Construction Syndicate, Limited, Westminster.—Debenture registered Aug. 3 for £70,000; holder, H. S. Leon, Bletchley Park, Bucks; a first floating charge on the undertaking and all the property, present and future, including any uncalled capital.

Northern Counties Electricity Supply Company, Limited, Newcastle-upon-Tyne.—Lien registered Aug. 5 for £500 5 per cent. debenture, part of £100,000; amount previously issued, £25,600; no trustees; charged on the undertaking and all the property, present and future, excluding the uncalled or unpaid capital.

British Westinghouse Electric and Manufacturing Company, Limited.—A trust deed, dated Aug. 2, 1904 (supplemental to trust deeds, dated Feb. 18, 1902, and Aug. 31, 1903, respectively), securing a further £225,000 debenture stock, created by Board resolution of July 22, 1904, has been registered. Property charged: freehold hereditaments at Stretford and Barton-on-Irwell, Lancs., lately forming part of the Trafford Park Estate, with buildings erected or in course of erection thereon (subject to certain rent charges affecting the same) and the company's general assets, present and future, including uncalled capital. The above is the same property as is charged by the trust deed of 1902. Trustees: Merchants' Trust, Limited, 63, Cornhill, E.C.

Davies, Kent, and Stewart, Limited (Electrical Accessory Manufacturers, London).—Issue on Aug. 4 of £1,050 debentures, part of a series created July 26, 1904, to secure £1,350, charged on the company's undertaking and property, present and future, including uncalled capital (if any). No trustees. No previous issue of same series

Woking Electric Supply Company, Limited.—Issue on July 16 of £500 debentures, part of a series created Nov. 2, 1899, to secure £25,000 charged on the company's undertaking and property, present and future, including uncalled capital. No trustees. Total amount previously issued of same series, £24,150.

Lien Discharged.

Metropolitan Electric Supply Company, Limited, London, W. Discharge registered Aug. 3 of charges dated July 30, 1901, Sept. 5, 1902, and Dec. 7, 1902, for securing the sum of £235,000.

PERSONAL.

On the occasion of his recent marriage, Mr. J. F. Magoris, chief assistant city electrical engineer, Hull, was presented on Friday last by the clerical, engineering, and works staff of the Hull Corporation electricity works with a handsome case of cutlery. The presentation was made in the presence of the whole of the staff, who, through their spokesman (Mr. G. Sykes), took the opportunity of wishing him and Mrs. Magoris long life and every possible happiness, and, in parenthesis, touched upon the cordiality which had always existed between themselves and their chiefs, Messrs. H. Bell (city electrical engineer) and J. F. Magoris.

The Mexborough Urban District Council have increased the salary of Mr. Senior, the electrical engineer, by £20.

Mr. R. G. Simpson, chief assistant engineer, Edinburgh Corporation, has been appointed electrical engineer of the Weymouth electricity supply department. The salary is £250 per annum, increasing by annual increments of £25 to £300 per annum.

Mr. H. J. T. Heather, formerly engineer of Moodie's Gold Mining and Exportation, Barberton, Transvaal, has been appointed electrical engineer to the Village Main Reef G.M.I., Limited.

Mr. G. H. Carter has been recently appointed resident electrical engineer to the Acton Urban District Council.

At the Norwich Electric Tramway Company's offices, Orford-hill, on Friday, Mr. W. A. Penman was the recipient of a combined spirit tantalus, cigar, and cigarette cabinet from the officers and employés of the tramway company, on the occasion of his leaving the company.

We are informed that Mr. G. A. Hughes and Mr. Adolph Wunderlick are retiring from the Charlton works of Messrs. Johnson and Phillips after 15 and 7 years' service respectively, having held the positions of works secretary and departmental manager. We understand that they are shortly to commence business on their own account as electrical manufacturers.

APPOINTMENTS VACANT.

Draughtsman. Box D 20, *Electrical Engineer* Office. See advertisement.

Switchboard Attendant, Kirkcaldy electricity works. Wages 25s. per week. Applications by 27th inst. See advertisement.

Agent, accumulator manufacturers. W., *Electrical Engineer* Office. See advertisement.

Plumber Jointers. Harland and Wolff, Limited, Belfast. See advertisement.

Resident Electrical Engineer, Willesden Urban District Council. Salary £250 per annum. Applications by Sept. 17. See advertisement.

Mains Assistant. Engineer and Manager, 27, Osborne-street, Whitechapel, E. See advertisement.

Resident Electrical Engineer, Hereford. Salary £200 per annum, and half pupils' premiums. Applications by 25th inst. See advertisement.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Ipswich.—The Electric Lighting Committee will shortly advertise for tenders for addition of boiler.

Pennas de San Pedro (Spain).—The Municipality require tenders for electric lighting for 20 years. Tenders by Aug. 25.

Paris.—The Posts and Telegraph Department, 123, Rue de Grenelle, require tenders for paper-insulated cables (11 lots) by Aug. 25.

Madrid.—Tenders are required by the Post and Telegraph Department for 70 tons of 4mm. galvanised iron wire and 70 tons of 2mm. bronze wire by Sept. 3.

Bucharest.—The Roumanian Government Railways require tenders for supply and erection of electricity plant and for installation for lighting several workshops by 27th inst.

Pangbourne.—Tenders are required for lighting the village during the coming winter, for the Pangbourne Parish Council. Particulars may be obtained of Mr. C. West, jun., clerk.

Batley (Yorks).—The Batley Working-Men's Club invite full specified estimates for the installation of the electric light on the club premises. Tenders to be sent to Mr. W. Booth, secretary, by Aug. 22.

Madrid.—Tenders are required by the Post and Telegraph Department for 9,000m. telegraph cable of 7 rubber-insulated wires, 2,000m. ditto of 28 paper-insulated wires, and 11,000m. cable of 7 steel wires by Sept. 6.

Hove (Sussex).—Tenders are invited for the supply, delivery, and laying, in the parish of Aldrington, of low-tension vulcanised-bitumen, dialite, or "leadless" paper cables, conduits, boxes, meters, etc. Tenders by Aug. 30. See advertisement.

Dublin.—The Lighting Committee of the Corporation of the City of Dublin are prepared to receive tenders for the supply of 500 alternating-current meters, single-phase and three-phase. Tenders to the Chairman, Lighting Committee, 3, Cork-hill, Dublin, by 12 noon on Aug. 23.

Madrid.—The Directorate-General of Administration ("Ministerio de la Gobernación") require tenders for the supply and upkeep for three years of continuous-current arc lamps, with a minimum of 64 lamp-posts. The total upset price is about £7,762. Local representation is necessary. Tenders by Aug. 24.

London, S.W.—The London County Council invite tenders for the manufacture, delivery, and erection of three electric car traversers at certain of the Council's tramway depôts in the South of London. Specification, etc., may be obtained at the County Hall, Spring-gardens, S.W. Tenders by 10 a.m. on Oct. 4.

Stoke-upon-Trent.—The Guardians of the workhouse invite tenders for two 13-h.p. electric motors; one 2-h.p. electric motor; electric cable; piping or tubing; junction boxes and frames. Specifications

Digitized by Google

may be seen at the Workhouse between 10 a.m. and 4 p.m. Tenders to Mr C. Daniel, clerk, Union Offices, Stoke-upon-Trent, by 9 a.m. on Aug. 24.

Penang.—The Municipal Council of George Town, Penang, invite tenders for the supply and delivery of tramcars, complete with motors, controllers, trolleys, etc. Specification, etc., can be obtained at the offices of Messrs. Preece and Cardew, 8, Queen Anne's-gate, Westminster, S.W. Tenders to Mr. R. M. Christie, 4, East India-avenue, London, E.C., by 12 noon on Aug. 24.

Greenwich.—The London County Council invite tenders for the manufacture, delivery, and erection at the tramways electricity generating station at Greenwich of the following plant: two 24in. centrifugal pumps and motors, one 3in. centrifugal pump and motor, two 8in. by 8in. three-throw air-pumps and motors, one 3in. artesian well pump, fixed and rotary strainers, etc. Specifications, etc., may be obtained at the County Hall, Spring-gardens, S.W. Tenders by 10 a.m. on Oct. 4.

Manchester.—The Directors of the Manchester Dock and Warehouse Extension Company, Limited, invite tenders for the wiring (for power and light) and electric lighting of five transit sheds (now in course of erection) on the southerly side of dock No. 9, in the county borough of Salford. Specification, etc., can be obtained at the office of Mr. W. H. Hunter, chief engineer to the Manchester Ship Canal Company, 41, Spring-gardens, Manchester. Tenders to Mr. F. A. Eyre, secretary, Manchester Ship Canal Company, 41, Spring-gardens, Manchester, by 10 a.m. on Aug. 30.

Australian Commonwealth.—Tenders will be received at the office of the Deputy Postmaster-General, Hobart (Tasmania), until noon on Sept. 30, 1904, for the supply and delivery at the General Post Office, Hobart, of one multiple metallic branching switchboard. Specifications may be seen at, and tender forms and conditions obtained from, the General Post Offices at Hobart, Melbourne, Sydney, Adelaide, Brisbane, and Perth. Tenders should be endorsed "Tender for Switchboard," and addressed to the Deputy Postmaster-General, Hobart. Tenders may be deposited in the tender-box at the General Post Office, Hobart, or, if sent by post, must be prepaid and registered. Tenderers must state the name of the country in which the switchboard will be manufactured.

RESULTS OF TENDERS.

Wednesfield.—The tender of Mr. H. Holloway has been accepted for the construction of the extended tramway track on the Wednesfield-road at £2,752. 15s.

Hackney.—The Guardians have accepted the tender of W. Wallace and Co., 151-5, Curtain-road, E., for fitting up a system of electric fire-alarm bells at their Homerton establishments.

Bermondsey.—The Borough Council have accepted the tender of Sunderland and Co., 39, Victoria-street, S.W., at £138, for the wiring of the staircases and courtyards of the Fulford-street dwellings.

Loughborough.—The Electricity Committee have accepted the tender of Bennis and Co., at £320. 7s. 10d., for two patent double machine stokers, including driving shaft and 2½ h.p. motor for driving same.

Erith.—The following tenders have been received for tramway rails and permanent way:

* Accepted.

Law Courts.—The order for extensions to the electric lighting of the Royal Law Courts of Justice has been placed with Messrs. F. A. Glover and Co., Limited, 10 and 12, Garrick-street, Covent Garden, London, W.C.

Warrington.—The Electricity Committee have accepted the tenders of Babcock and Wilcox, Farringdon-street, London, at £957, for four mechanical stokers, and Bell Bros., Ravensthorpe, Yorkshire, at £450, for water-softening plant.

Accumulators.—The Hart Accumulator Company, Limited, Marshgate-lane, Stratford, London, E., report an order from the Bradford Corporation for 260 of their standard central lighting type cells, automatic reversible booster, and switchgear.

Cables.—Messrs. W. T. Glover and Co., Trafford Park, Manchester, have obtained from the Johannesburg Town Council the contract for supplying and laying new distrine paper lead-covered, distrine paper leadless, and vulcanised rubber cables. The total of the contract will be considerably over £100,000.

Warrington.—The Corporation have accepted the tender of R. W. Blackwell and Co., London, at £737. 14s. 8d., for the supply, delivery, and erection of steel poles, trolley wires, etc., forming complete overhead equipment for about 550 yards of double track, including special arrangements at the swingbridge over the Manchester Ship Canal.

Condensers.—The Mirrlees-Watson Company, Scotland-street, Glasgow, report the following orders for condensing plant: surface—Leeds Corporation lighting; Northampton Corporation; Bradford Corporation (repeat), per J. Musgrave and Sons; Egyptian Government; Redpath, Brown, and Co.; J. Musgrave and Sons (for South Africa), Burgh of Greenock; Whitby Urban District Council; Partick Electric; G. H. Powden, Manchester; Premier (Transvaal) Mining Company, per Fullerton, Hodgart, and Barclay; Inverask Paper Mills, per British Westinghouse Company; Folkestone Electric, per Edmundson's Electricity Corporation; Cardiff Electricity Works; Willesden Urban District Council; Madeira Electric Light Company; Bristol Corporation, per Willans and Robinson; jet—Clyde Valley Electric Power Company, per British Westinghouse Company; Kilmarnock Electric, per Aiton and Co.

BUSINESS NOTES.

TRACTION.

Wolverhampton — The new Bushbury route is being well patronised.

Ayr.—The Corporation Tramways Order Confirmation Bill has received the Royal assent.

Coventry.—The company have decided to raise a further sum of £10,000 for working capital, the loan to be charged on the company's undertaking.

Tynemouth.—The Corporation are approaching the company with a request that a line should be run down to the Fish Quay, so that the congestion of traffic may be relieved.

Tynemouth and District Electric Traction Co.—The directors have decided to pay an interim dividend for the half-year ended June 30 at the rate of 5 per cent. per annum.

Cambridge.—The Town Council have received a report from Messrs. Kincaid, Waller, Manville, and Dawson, as to the various routes which should be adopted in the event of the electrification of the tramways being carried out.

Leicester.—A trial trip has been made on the Aylestone-road section, everything going smoothly. The official opening of the route will not, however, take place before the end of the month or early in September. Experiments are being carried on with a new step.

Raworth's Traction Patents.—At a special meeting of the Walthamstow District Council it was unanimously decided to ask their consulting engineer, Mr. J. Enright, to bring up a report upon Raworth's automatic regenerative control system for electric traction.

Diesel Engines.—One of the largest stations equipped with Diesel engines is that of the Kief tramways, where six engines are installed, with an aggregate output of nearly 2,000 b.h.p. Diesel traction stations in the United Kingdom include Birmingham, Dudley, Stourbridge, Rothesay, and Greenock.

South Australia.—Mr. Bradford, the electrical expert who has been engaged by the South Australian and Victorian Governments to report upon the electrification of suburban railways and on the South Australian tramways generally, has entered upon his work at Adelaide, but his report is not expected for some time.—*N.S.W. Railway Budget.*

Western Australia.—Messrs. Noyes Bros., electrical engineers, have, states the *N.S.W. Railway Budget*, entered into a contract to construct and equip electric tramways and an electric lighting system for the municipalities of Fremantle and East Fremantle, at a cost of £80,000. The contract time is 18 months, but the contractors expect to complete the work in 12 months.

Birstall.—The District Council have received a communication from the British Electric Traction Company stating that it was proposed to commence the reconstruction of the Dewsbury, Batley, and Birstall tramways at an early date, and forwarding plans, etc. A similar communication has been addressed to the General District Council, as mentioned in our note last week.

Halifax.—The traffic returns for the fortnight from the 27th ult. to the 10th inst. establish a new record for the town. The amount taken on all the routes was £4,046. 9s. 8d. The nearest approach to this

Digitized by Google

was £3,935. 16s. 11d., collected in the fortnight ended June 3, 1903, in which period Whit-week occurred, while in the fortnight including Whitsuntide this year the takings totalled £3,593. 6s. 8d.

Wakefield.—The Wakefield and district tramcars commenced running on Monday. There will be a regular service from the centre of the town to Belle Vue and Sandal, Horbury and Ossett, and Outwood, Lofthouse, and Leeds. A branch to Rothwell will shortly be opened, and within a short time the system will couple up with Normanton, Castleford, Pontefract, and Knottingley.

Dewsbury.—The Corporation have agreed to purchase the undertaking of the Yorkshire (Woollen District) Electric Tramways Company in the borough of Dewsbury for the sum of £52,500 (less the rolling-stock), the concern to be leased for 30 years, at the expiration of which term it will belong absolutely to the Corporation. The Corporation have ordered the necessary borrowing powers to be obtained.

Rangoon.—*Indian Engineering* announces that the negotiations relative to the license for electric traction and lighting in Rangoon, of which Messrs. Darwood and Co. are the concessionaires, have now been completed. It is hoped that the work will be put in hand by November. Unusual interest attaches to the venture from the fact that the present steam tramways were constructed by the late Mr. J. W. Darwood, whose family are the concessionaires for the new system.

Dulverton-Minehead.—The Watchet Urban Council and the Williton Rural Council have passed resolutions in favour of the suggested light railway between Dulverton and Minehead, or Watchet. The Minehead Urban Council are also disposed to favour the scheme. Lady Carnarvon, as one of the landowners, has written to say that her co-operation must depend upon the valley of the Haddes being left untouched. The Dulverton Urban Council will hold a special meeting to further consider the matter.

Walsall.—The town clerk has been instructed to apply to the Board of Trade to inspect the overhead equipment of the old tramways, which has now been brought up to the present general standard, in accordance with the Board's requirements. It has been arranged with the Electricity Committee that the charge for current for tramway purposes shall be 2d. per unit up to June 30, 1904, and thereafter 1½d. per unit, irrespective of the quantity used, until such time as any new arrangement may be come to after the end of the present year.

South Lancashire Traction and Power Company, Limited.—An agreement has been registered under which the company issues to the Electric Conversion Syndicate, Limited, £47,000 prior mortgage debenture stock in exchange for a similar amount of first mortgage debenture stock; charged on shares in the South Lancashire Tramways Company and the Lancashire Light Railway Company, certain lands and hereditaments, and all other assets, including the uncalled capital, ranking in priority to the first mortgage debenture stock secured by a trust deed, dated Jan. 28, 1901.

Aberdeen.—A report was presented last week to the Tramways Committee of the Town Council on the operation of the scheme of workmen's cars. On all the routes (except Woodside) a considerable loss was shown; but it was resolved to give the arrangement another month's trial before deciding whether these early morning cars should be continued or not. The question of the fares for the ensuing year was also discussed, and it was decided to adhere to the existing rates for the present, except in regard to the Woodside route, on which the committee will recommend the Council to make a reduction.

Aberavon.—Representatives of the Highway and General Purposes Committee and of the tramway promoters have inspected the route of the proposed system. The top of Water-street would require to be widened a few inches, but there was no engineering difficulty in constructing the line, as was feared, by the narrowness of this thoroughfare. It was subsequently decided that the Council approve of the scheme and route, provided the engineering difficulties could be overcome to the satisfaction of the Town Council, and that the scheme be completed within two years after the syndicate had obtained parliamentary sanction.

Middlesbrough.—The Corporation having received numerous complaints concerning the excessive speed at which the electric tramcars pass through the town, recently decided to prosecute the offenders. As a result, three motormen employed by the Imperial Tramways Company were charged with driving their cars at a greater speed than eight miles an hour. In one case a fine of 30s. was imposed, the other two cases being adjourned for further evidence. On behalf of the company, it was stated that the motormen having been given official instructions regarding the speed of cars, they would not have their fines paid by their employers.

Belfast.—At last week's meeting of the Tramways Committee, the town clerk was authorised to communicate with the solicitors for the Belfast Street Tramways Company in regard to the appointment of an arbitrator. The city surveyor (Mr. H. A. Cutler) and the electrical engineer (Mr. V. A. H. M'Cowen) submitted their joint report on the various systems of electric traction, and recommended the adoption of the overhead trolley system on the score of cost. The committee will recommend the Corporation to adopt this system. On the assumption that the overhead method is adopted, Messrs. Cutler and M'Cowen estimate the total outlay necessary (excluding the purchase of the company's undertaking and parliamentary expenses) at £827,000.

Leith.—In pursuance of the decision of the Town Council to make enquiries respecting all systems of traction, in view of the advanced stage now reached by the Council's tramway provisional order, a party, consisting of the town clerk, treasurer, borough engineer, and consulting tramways engineer, with four members of the Council, visited Hull last Saturday for the purpose of obtaining information on tramway matters. They were met at the Hull station by the city engineer (Mr. White) and Mr. Wilkinson (the tramways electrical engineer), who conducted them over the different routes, car-sheds, and tramways power station. The Leith representatives expressed great admiration at the substantial and well-laid track, the wood-paved streets, tramways power station, and buildings. After inspecting other improvements, the party left for London.

Birmingham.—It is stated that the opening of the Dudley-road route may be expected in a month's time. The Birmingham and Midland Tramways Company have ordered 24 new cars, in addition to those already in operation on the Black Country portion of the line, and 12 are ready for almost immediate use. By the opening of this route it will be possible to travel by electric car from Congreve-street direct to Kinver, a distance of 14 or 15 miles, with only one change—at the Fish, beyond Wordsley. The new cars will be provided with a covered top, on the Bellamy principle. The directors of the company were desirous of introducing the covered top on the Bristol-road route, but objection was offered by the Corporation. It is stated, however, that the authorities have of late relaxed their attitude, and there is a disposition now to adopt a similar contrivance shortly on the municipal cars running to and from Aston.

Sydney.—It is anticipated, says the *New South Wales Railway Budget*, that the cable tramway system from King-street to Ocean-street will be superseded by electricity at an early date. Some of the steam-boilers required for driving the new machinery necessary to generate additional electricity at the Ultimo power-house have arrived, and it is expected that they, together with the new machinery, will be in working order towards the end of the year. This will permit of the cable system being finally abandoned for the speedier, more comfortable, and certain electric system. The conversion from cable to electricity will not, it is understood, involve an undue waste of existing materials and works. The conduit in which the cable runs will, of course, be valueless, but the permanent way will be utilised. The same will be the case with the tramway shed and steam power-house at Rushcutter Bay. It is quite true the engines will not be required, and it is understood the Railway Commissioners will sell them, but the whole of the building will be utilised for the housing of electric cars and carrying out repairs.

Manchester.—The Board of Trade has held an enquiry respecting the new by-laws proposed by the Corporation for the regulation of tramway traffic in the streets. A suggestion was made by Sir Herbert Jekyll that with regard to the general regulation the parties should consider how far the "model" by-law framed to suit the traffic on the London United Tramways would meet the case in Manchester. This by-law read as follows: "The driver of every car shall so drive the same that it shall not follow a preceding car at a less distance than 50 yards, except in cases of emergency, when the driver shall comply with the directions given by the authority controlling traffic on the spot. No car shall be stopped within 15 yards of another car on a parallel line of rails, nor within 15 yards of the intersection or junction of two or more streets or roads." This proposal was accepted as satisfactory by Mr. Forbes Lankester on behalf of the Horse-owners' Association. Mr. M'Elroy, general manager of the Corporation tramways department, considered that a 15 yards' interval was the right figure in general, but the Corporation were prepared to agree to 100 yards in regard to Portland street.

Devonport.—The Devonport and District Tramway Company have now completed the system of tramways for which the company and the Corporation obtained powers, the last section to be completed being examined last Friday by Major Druitt on behalf of the Board of Trade. The line runs from Milehouse to Ford, being a continuation of the St. Levan-road section. The road has been made by the Corporation, and has been laid with a single line with loops by the company. At the inspection Major Druitt was accompanied by Mr. J. C. Tozer and Alderman J. Goodman, chairman and vice-chairman of the Corporation Tramways Committee; Mr. R. J. Fittall, town clerk; Mr. J. F. Burns, borough surveyor; and Mr. J. W. Endean, general manager Devonport and District Tramways Company. A car was run over the extension, which bore the test admirably. The wires, etc., were examined by the inspector, who expressed himself as thoroughly satisfied. Permission to use the section will, it is expected, be forthcoming in the course of the next few days. Although the powers of the company and Corporation are now exhausted, it is proposed to apply for permission to extend the St. Budeaux section to the parish church.

Morecambe.—At a meeting of the directors of the Morecambe Tramways Company and the Tramways Committee several points with respect to the electrification of the tramways were discussed. The directors stated that it would be impossible to satisfactorily electrify the trams unless the road from the Midland Hotel to Albert road was widened to such an extent as to provide a road of 40ft. between the kerbs, so as to allow of a double track of rails, and before proceeding further in the negotiations the directors wished to see a plan showing how such a road widening could be effected to the satisfaction of the Corporation. The directors stated that they would not be at the expense of such road widening unless the expense was added to capital account, so that such expenditure could be allowed by the Corporation in case they at any time took over the undertaking. The Town Council have decided to prepare such plan. A communication is expected from the company shortly as to the maximum amount of current which will be required per day, and the Electric Lighting Committee are to make and submit a calculation of price for the energy to be supplied. In regard to the Bare section, the Council are to consider further the price they will be prepared to accept for same.

York.—The communications which have been passing between the York Tramways Company and the Corporation with regard to the possible acquisition of the company's lines by the municipal authority, were referred to by the chairman of the company (Mr. Joseph Kincaid) at the half-yearly meeting. Mr. Kincaid said that the Corporation had communicated with the company with regard to the taking over of the lines, but only preliminary letters had passed. The directors

Digitized by Google

had expressed themselves as perfectly willing to meet the views of the Corporation, on fair terms, and no doubt a negotiation carried on between a willing buyer and a willing seller would prove, he hoped, to end in a satisfactory arrangement. The company would, of course, prefer that the Corporation should take over the lines sooner than go on as they were at present, because they felt their undertaking was not satisfactory to the town. At the same time the company themselves were willing, under certain conditions requiring the consent of the Corporation, to make the improvements and extensions necessary to make the undertaking satisfactory to the population of York. The company would continue to negotiate in a way that the directors hoped would satisfactorily solve a thorny question.

Bury.—Another section of the Corporation tramways has been completed and opened for traffic, the latest addition to the system being the section by Bolton-street and Bolton-road to the barracks. A trial trip on the section was run on the 9th inst., the start of the car from the Market-place and its progress to the barracks and back being witnessed by very large gatherings of spectators. A number of members and officials of the Town Council took part in the initial run, amongst those present being Messrs. W. Clough (tramway manager), A. W. Bradley (borough engineer), S. J. Watson (electrical engineer), and C. Satterthwaite (Macartney, McElroy, and Co.). After the run to the barracks the car was taken to Jericho and to Blackford Bridge for the purpose of testing the magnetic brake with which it had been fitted prior to leaving the depôt. The next morning Major E. Druitt, R.E., inspected the section on behalf of the Board of Trade. He specially examined the laying of the setts on the outside of the rails at the barracks end of the section. After traversing the route, Major Druitt expressed himself as satisfied, and fixed the following speed limits: Bolton-street, 10 miles an hour; Bolton-road, 12 miles; curves, four miles. Subsequently a service of cars was commenced to the barracks, and each car was well patronised.

Newcastle.—The annual report of Mr. A. E. Le Rossignol, general manager and engineer of the Corporation tramways, has been issued to members of the City Council. It states that the result of the working of the tramways for the second financial year shows that the total revenue from all sources is £185,027. 12s. 9d.; total working expenses of the tramways and of the arc lighting of the city £121,557. 14s. 9d., making a gross surplus of £63,469. 18s. The total working expenses per car mile were 7·19d. as against 6·35d. for the previous year, but there had been a decrease in all the items making up the working expenses with the exception of the item for rates, taxes, etc., and the item for maintenance and renewals, both of which show a considerable increase. Under the former item the department had paid this year over £5,000 in rates, whilst the increase in the latter item for maintenance and renewals was an exceptional one, which had been necessary to keep the plant from depreciating rapidly. The chief increase in maintenance this year had been incurred in connection with the permanent way and the cars. Out of the gross surplus a larger amount than last year by over £8 000 had been required for increased interest on and redemption of capital. A large proportion of this had been expended on work which had been carried out this year, but had not yet had time to produce revenue or come into use. During the 2¼ years of working just completed productive capital had been redeemed out of revenue to the following extent: redemption of capital during 15 months' working up to March 25, 1903, £19 851; redemption of capital during 12 months' working up to March 25, 1904, £20,190. In addition, the charges for interest and redemption on capital unproductive whilst used in construction of work and not yet ready to yield revenue, have all been paid out of revenue, instead of (as was done in many cases) paying these charges out of capital. The amounts paid off entirely in this way were as follows: interest and redemption incurred during the construction of the tramways prior to their opening on Dec. 16, 1901, £21,278. 11s. 11d.; interest and redemption on works constructed during 15 months up to March 25, 1903, and not productive of revenue till the next year, £9,285; interest and redemption on works constructed during 12 months up to March 25, 1904, and not productive of revenue till next year, £6,900—total, £37,463. 11s. 11d. Mr. Le Rossignol recommends the Tramways Committee to form the nucleus of a reserve fund now by devoting to it the balance remaining this year after paying off the last instalment of the loan for interest and redemption during construction advanced by the Finance Committee. He also recommends a reduction in the distance of the ½d. sections, and suggests that longer 1d. stages would be preferable to continuing the workmen's cars, which are freely used by ordinary passengers. The extension to the boiler-house is now complete, and the boiler plant is capable of supplying steam to the new 3,000-h.p. engine, which is approaching completion in the engine-house, where the necessary additions to the switchboard for the new generator have been made. In addition, a gallery has been erected at the west end of the engine-house to accommodate the switchboard for providing current at 250 volts to the municipal buildings,, and a motor-converter installed to supply current at 100 volts to the town hall, in order to avoid alteration of the existing wiring in that building. The construction of the new car-shed in the west end of the city, at Wingrove, has proceeded well, and the building is almost ready for use. Its cost will be about £11,479, or £530 less than the contract price. The following is a summary of the year's working: single miles of line open for traffic, 45; passengers, 39,715,120; population served by tramways, 257,000; average journeys *per capita* per annum, 155; car mileage run during the year, 4,059,907; total kilowatts generated, including lighting, etc., 7,757,885; average number of passengers per car mile, 9·8; average fare per passenger, 1·1d.; traffic revenue for the year, £180,630. 12s. 2d.; average traffic revenue per car mile, 10·68d.; total revenue for the year, £185,027. 12s. 9d.; average total revenue for the year, 10·94d.; total working expenses for the year, including street-lighting, £121,557. 14s. 9d.; average total working expenses per car mile, 7·19d.; average net working expenses per car mile, including proportion of costs chargeable to street-lighting, 7·00d.; percentage of net working expenses to traffic receipts, 65·5 per cent.; total capital expenditure at March 25, 1904, £1,054,492. 15s. 8d.; total number of cars in stock in March last, 165; number of cars in course of construction, 12. Since the opening of the system the total of car miles run aggregate 7,832,121; passengers carried, 77,895,183; receipts, £352,131. 8s. 5½d.; receipts per car mile, 10·79. The Tramways Committee have arranged that the relaying of the lines and repairing of the tramways generally shall be vested in the hands of Mr. Edge, the city engineer, and the Town Improvement Committee, instead of sub-dividing it, as in the past, between the Tramways Committee and the Town Improvement Committee, which had caused considerable confusion and expense.

LIGHTING AND GENERAL.

Birkdale.—The exchange for the underground telephone service will be opened at the end of the present month.

Berwick.—The lighting of the bridge by electricity has been remitted to the Lighting Committee with powers.

King's College.—The session for 1904-5 commences Wednesday, Oct. 5. Particulars will be found in another column.

Ossett.—Mr. G. Vaughan Fowler, Warwick, intends to apply for a provisional order for the supply of electricity within the district.

Carnarvon.—Sanction has been obtained to the borrowing by the Town Council of £17,315 towards erecting electric light buildings.

Change of Address.—Messrs. Edward C. Herbert, Limited, have removed their works and registered offices to Rosamond-street, East Manchester.

Frome.—The electric lighting of the streets has been started, and the contractors are being urged to complete the whole of the street lighting as speedily as possible.

Sligo.—The Corporation have passed a resolution drawing the attention of the Government to the necessity of connecting the town (the terminus of three important railways) with Dublin by the construction of a trunk line.

Ashton.—The Guardians have received a report from Mr. Appelbee electrical engineer for the borough of Ashton, relative to the cost of electric light in similar institutions to that of the workhouse, which is estimated at £1,500, exclusive of £200 for telephones.

Competition.—The Association des Industriels de Paris, Rue de Suède 3, offers a premium of £240 for the best apparatus showing at any time the actual charge of an electric conductor. The sum may be divided should the merits of the apparatus submitted warrant it. The competition closes Dec. 31, 1904.

Warminster.—The Rural District Council had to guarantee £26 before the postal authorities would extend the telegraph to Sutton Veney. There was a deficit of £2. 12s. on the year's working, which sum is paid in equal proportions by the General Post Office and the District Council, the latter body raising the money from Sutton Veney as a special charge.

Morley.—Mr. J. E. Ellis (electrical engineer) in his last report states that the output from the electricity works during the month ending June 30 was 5,895 units, as compared with 6,080 units the same period last year, being a decrease of 185 units. The number of lamps connected during the month was 34, the total number connected to date being 11,814.

Greenock.—The accounts of the electricity department of the Corporation for the past year show a deficit of £2,100, stated to be chiefly due to the Board of Trade decision in the arbitration case between the Corporation and the tramway company. The decision compels the department to supply energy at a figure much lower than they thought they were entitled to charge according to their lease.

Kirkintilloch.—The gas manager having made a call on the shopkeepers in the centre of the burgh, in which the Council propose to begin operations in electric lighting, met with good promises of support. It is proposed to erect small works on a part of the ground recently purchased for the erection of the town hall. If the venture succeeds, the plant can be removed and used when larger works become necessary.

Superheated Steam.—We are informed that Messrs. Easton and Anderson, Broad Sanctuary-chambers, 20, Tothill-street, S.W., have taken over the superheater business until recently carried on by Easton and Co., Limited, of London and Erith, and that in future all superheaters under either the Schmidt or the Easton patents will be constructed for them to their designs and under their own supervision by Messrs. John and Edward Wood, of the Victoria Foundry, Bolton.

Hove.—No further action is to be taken on notice served on th Brighton Corporation with reference to carrying out the work themselves in connection with laying the proposed electric cables along Old Shoreham-road. The suggested terms between the two authorities with regard to laying mains have been agreed to. Tenders are to be obtained for carrying out proposed works south of Hoove Lea, 4, Courtenay-terrace, and on the south side of Shoreham-road, opposite Mills-terrace.

Catalogue.—The latest catalogue of the Electrical Company, Limited, 121-125, Charing Cross-road, London, W.C., contains many novelties which they stock and which are of great importance in the development of Nernst lamps. We are informed that the company have made arrangements with the patentees of these lamps in order that their customers may be fully protected against infringement of patents. By an agreement with the patent-holders and the different licensees, special discounts have been fixed which came into force on Aug. 1, and to which the respective sellers are bound to strictly adhere. This new arrangement is of mutual benefit to both sides, preventing the trade from underselling one another.

Digitized by Google

South Metropolitan Electric Light and Power Co.—The company's preference share register will remain closed to the 31st inst. inclusive, for the preparation of dividend warrants payable 31st inst. in connection with interim dividend for the half-year ended June 30 on 50,000 7 per cent. cumulative preference shares.

Swansea.—The revenue from the electricity supply for the year ending March, 1904, was £10,871, as against £8,249, an increase of £2,621; the total revenue £10,938, as against £8,300. The gross profit was £5,876, as against £4,578, leaving a net profit, after payment of all charges, including interest and sinking fund, of £744—a highly satisfactory result. The total units sold aggregated 871,555, being 50 per cent. higher than in 1903, the average total cost being 1·38d. per unit.

St. Louis Exhibition.—We have received from the enterprising manufacturers of the "Swan" fountain pens a well-printed booklet of 15 photographic views of the various handsome structures at the St. Louis Exhibition. Each building is concisely described and cost stated. Messrs. Mabie Todd and Bard intimate that they will gladly send a copy free to all readers, mentioning this paper, who apply by postcard to any of their establishments: 93, Cheapside, London, E.C.; 95, Regent-street, London, W.; 3, Exchange-street, Manchester.

Long-Distance Telephone Extension.—On and after Sept. 1 telephonic communication will be established between East Coast towns and the following Continental centres: Amiens, Aniche, Armentieres, Arras, Bethune, Calais, Cambrai, Denain, Douay, Dunkirk, Fournies, Lens, Lille Masnieres, Montreuil, Peronne, Roubaix, St. Omer, St. Quentin, Tourcoing, and Valenciennes. The service will be worked through the Anglo-French and Anglo-Belgian telephone service. The usual fee of 8s. will be charged for three minutes' conversation.

West Hartlepool.—In the last report of the Electric Lighting Committee, the engineer (Mr. Friederichs) stated that the yearly overhauling of the electric plant had now been completed, and, taken generally, it was found in excellent condition, and although the engines had had nearly double the amount of running during the last year, their condition was really splendid. The repairs to the engines were less than what had to be done last year. Taking the engines and dynamos as a whole, their condition was better now than when handed over to the Corporation by the makers.

Hornsey.—The electrical engineer's report on the June quarter's working of the Council's electricity undertaking shows that the total costs, as compared with the corresponding quarter of last year, are over ¼d., or about 16 per cent. less. The repairs and maintenance item is very heavy this quarter, but this is accounted for by all the plant having been overhauled, and the first instalment of accumulator maintenance having been paid. The coal item is especially satisfactory, showing a drop of ·49d., or about 45 per cent. Seven hundred and thirty-three additional 8-c.p. lamps were connected up during the month of June, making a total of 27,223 for the 499 private consumers.

King's Lynn.—The accounts for the year ended March 31, 1904, with regard to the electricity fund revenue account, shows that the income for that department amounted to £6,497. Sale of current per meter brought in £3,270, and by contract £24. Public lighting revenue amounted to £1,991, rental of meters £155, and sale and repairs of lamps, etc., £1,054. The items of expenditure consisted of generation of electricity £1,466, distribution £874, public lamps £227, rents, rates, and taxes £170, management expenses £373, law and parliamentary charges £13, and insurance £15, a total expenditure of £3,141, leaving a balance of £3,355 to be carried to net revenue account. Out of this amount £1,285 was paid for interest, and £1,580 went in instalments for the reduction of principal.

Saffron Walden.—The application of the National Telephone Company to run telephone wires along the Little Walden-road to connect Little Chesterford Park with Saffron Walden exchange has been granted under the following conditions: "That the wires be placed underground for a distance of about 1,200ft. in a northerly direction from Bryd's Farm-lane; also along the frontage of the property of Mr. E. B. Gibson; and also at the junction of Westley-lane with the road, if, in the opinion of the surveyor, this was necessary. That the poles be painted black and capped with turned finials. That a rent of 1s. be paid in respect of each pole, which shall be removed on three months' notice from the Council." The Council intend to proceed with the application for the electric lighting loan as soon as practicable.

Surbiton.—Messrs. Talbot and Stevenson having reported that the provision of a third boiler and engine at the electric lighting works was absolutely necessary to ensure the proper supply, the extension, which is estimated to cost £4,400, has been approved by the Council. It appears that on Friday and Saturday nights last winter the maximum load on the station reached 109 kw. There were at that time about 6,500 8-c.p. lamps fixed. The total number now fixed is about 9,000, and it is expected that by January next there will be about 1,200 more, and to supply these the load will probably reach 190 kw. The two sets now in use are each capable of developing 100 kw., so that unless the extension is made before the coming winter the two sets would be called upon to work together at full load, and it was unwise to work an electricity station without a reserve engine.

Whitworth.—The various local authorities interested in the question of the supply of electricity recently discussed the subject. All the Councils represented, except Littleborough, who have already obtained their electric lighting order, have received notices from the Lancashire Electric Power Company, Limited, and Messrs. Foote and Milne, Limited, of their intention to apply for electric lighting orders, but all have not adopted the course taken by the Whitworth Council—viz., in giving notice that they should oppose any application by those firms. Some of the districts seemed to think that the cost of applying for their own orders would be prohibitive, but the general opinion was that it was highly desirable for district councils to apply for orders themselves. Subsequently the District Council passed a resolution affirming the desirability of applying for a provisional order. In view however, of the fact that no provision has been made in the year's estimates for the cost of such order the matter stands deferred until next year.

London Gazette.—The last day for receiving proofs in the estate of the Warrington and District Electric Light and Power Company, Limited, 115, Sankey-street, Warrington, Lancaster, is Aug. 26, 1904. Edwin Bradshaw, 4, Egypt-street, Warrington, and Edward Johnson, 78, King-street, Manchester, have been appointed liquidators. The partnership between James Mitchell Hewitt and William Gould Rhodes, carrying on business as consulting engineers at Tower-chambers, Brown-street, Manchester, under the style of Hewitt and Rhodes, has been dissolved by mutual consent. The partnership between James Hall and Arthur Hackblock, carrying on business as electrical engineers at 1, Arcade-street and St. Matthew's-street, Ipswich, and at Lowestoft, under the style of Hall and Hackblock, has been dissolved by mutual consent. A general meeting of the members of the British Electromobile Company, Limited, will be held on Sept. 21, 1904, at 12 o'clock noon for the purpose of having an account laid before them showing the manner in which the winding-up of the company has been conducted and the property disposed of. P. D. Leake, liquidator.

Lowestoft.—The accountant has submitted the following report of estimated and actual income and expenditure for the half-year ending June 30 last: Expenditure—generation, estimate £2,180 (actual, £2,792); distribution, £100 (£31); public lamps, £110 (£173); rates and taxes, £100 (£105); management, £468 (£507); insurance, £54 (£19); interest and sinking fund, £2,010 (£1 277)—total, £5,022 (£4,904). Income—private lighting, estimate £2,200 (actual, £2,089); slot meters, £7 (£8); power, £160 (£264); traction, £1,200 (£1,401); public lighting, £600 (£678); meter rents, £95 (£110); sundries, — (£5)—total, £4,262 (£4,555). To be provided from rate, £349. It has been decided that as from April 1 last, being the date on which the Council's new financial arrangements started, this committee should take over the undertaking as a going concern, and be responsible for all liabilities incurred, and take the advantage of all assets of the undertaking as from that date. The resident engineer's last report shows that there are now connected to the mains 534 consumers, representing 26,945 8-c.p. lamps. During the month 11 new consumers have been connected, representing 1,347 8-c.p. lamps. The engineer reported that he had received an application from the proprietor of the Hippodrome for permission to place a direction plate "To the Hippodrome" on the arc lamp post at the corner of Suffolk-road. The committee recommended that the application be granted at a rental of £1. 1s. per annum, the design and size of the plate to be approved by the engineer, and to be subject to a month's notice of removal, and to a proper agreement being entered into.

Ipswich.—Messrs. Kennedy and Jenkin in a recent report stated that they have investigated, with Mr. Ayton's assistance, the probable demand for power in connection with lighting, motors, and tramways likely to be dealt with by the generating station in the coming winter. They say that it appeared necessary to allow for the equivalent of 30,000 8-c.p. lamps connected to the lighting mains. Allowing for about 60 per cent. of these alight at once, 900 i.h.p. must be available to supply the current. With 36 cars they would have to provide at least 600 i.h.p. to supply power to them. The total for the lighting supply and for the tramways which must be available next winter was, therefore, about 1,500 i.h.p. As regards engines and dynamos, the power available was ample, as allowing a proper proportion of spares they would have something like 1,790 i.h.p. available in the station. The boiler power, however, was not as great as that of the engines and dynamos, as allowing one boiler to be laid off, they would have the equivalent of 1,560 h.p., supposing the engines were running condensing. Should the supply of condensing water fail, or any other such cause make it necessary to run non-condensing for a time, the three boilers would only give sufficient steam for about 1,300 h.p. This was not sufficient to supply the 1,500 h.p. required for the lighting and tramways. No doubt, with the help of the fourth boiler, they might be able to get through the winter, but it was undesirable to run matters so close as this, as any failure in the supply would mean a very serious check to the prosperity of the undertaking. As consumers were coming on so rapidly, they advised the order of an additional boiler. The cost of the boilers originally supplied (including all pipes, valves, and mountings) was at the rate of £1,255 each. The Council supply now an equivalent of 21,612 c.p. Tenders for an additional boiler are to be invited.

Mansfield.—At an enquiry last week into the application of the Town Council for sanction to borrow £15,000 for the purposes of the electricity undertaking, the town clerk explained that under the provisions of the Mansfield Corporation Act the Council had borrowed £50,000 for the purposes of the electrical undertaking, and they were now applying for an additional £15,000 in order to make up the total estimate of the undertaking, which was £65,000. The works were practically complete, and the current was being supplied, the formal opening taking place on June 17 last year. Mr. R. Hammond, consulting engineer, stated that during the first quarter after the works were opened the number of lamps connected was 5,512, at the end of the second quarter 7,282, at the end of the third quarter 7,854, at the end of the fourth quarter 9 154, and up to date 9,700, the number of customers having increased from 60 in September, 1903, to 112 up to date. Combined with the electrical undertaking were also works for the burning of refuse. He said the £50,000 estimate had been drawn up at an early stage of the undertaking, but after working out the details it was considered wise to make amplifications, especially with reference to the refuse destructor, which was capable of destroying about 50 per cent. more than was originally intended. During a recent test of the refuse destructor the electrical plant had been worked solely on the boilers of the refuse destructor, the steam being raised by the

Digitized by Google

fumes from the burning refuse, and for 15 hours a set of generating plant had been driven entirely from the refuse, that generating plant supplying the town with electricity. It was originally intended that refuse destructor cells should be provided to deal with 33 tons, but at a recent test they got 52 tons, they having put down six cells instead of four. Four out of the six cells had dealt with 52 tons, so that practically they had a capacity of 98 tons of refuse, and practically 50 per cent. more than was originally intended.

Ormskirk.—The Urban District Council have approved the National Electric Construction Company's electric lighting scheme under which the Council will borrow the necessary money for the works, which will be constructed by the company. The latter will run the undertaking, and guarantee all repayments of loans and interest. All excess of profits over 3 per cent. go to the Council for the first 10 years, and afterwards for five years will be equally divided. Prices for current must not exceed 2¾d. per Board of Trade unit for public lighting, 5d. on the flat-rate system for private lighting; on the maximum demand system 7d. per Board of Trade unit for the equivalent of one hour's use per day per quarter, and 3d. per Board of Trade unit for all current consumed afterwards. Power on the maximum demand system 4d. per unit for the equivalent of one hour's use per day per quarter, and 1½d. for all current afterwards. The company will reimburse all expenditure in connection with provisional order, raising the loan, preparing the agreement, and fees of consulting engineers. The Council may after seven years, upon payment of 10 per cent. on the capital expenditure, take over the undertaking; after 10 years upon payment of 7½ per cent.; and after 15 or 20 years without any premium upon the Council paying all moneys to the company. The company will find the capital for a free wiring scheme under which consumers may have installations put in at a rental of 4½d. per lamp (up to 32 c.p.) per quarter. All losses will be made good by the company, who, in addition to the security afforded by their share capital, are prepared to allow the Council to retain 10 per cent. of the total contract price, reduced to 6¼ per cent. at the end of the second year, to be extended for five years. On the works paying, the retention will be refunded, with the exception of £250 to be held by the Council for five years. If the estimates of the cost of carrying out the works exceed £15,000, the Council have the right to reconsider their position, and to terminate the contract. The agreement contains the proviso that it is subject to the Local Government Board sanctioning the loan, and becomes null and void if such sanction be not obtained.

Dumbarton.—The following letter from Messrs. Crompton, of the Electric Supply Corporation, Limited, has been remitted to the Bills and Electric Committee, with powers: "With reference to the agreement between this company and your Council for the establishment of electric lighting in Dumbarton, my directors, at their meeting on the 25th ult., ordered the work for the establishment of the electric lighting undertaking to be proceeded with forthwith. Meanwhile, however, the directors have been approached by the promoters of a Scotch water-power scheme, having for its object the generating of electricity from falls at Loch Sloy, and delivering electrical energy in various places. The promoters of that scheme have asked that this company do make an agreement with them to take current at high pressure at the Dumbarton boundary, the company transforming the current into a lower pressure for the purpose of distributing the same to the consumers in the burgh. My directors are favourably considering this scheme, and if they can obtain proper financial guarantee, they will be disposed to go further into the matter, but inasmuch as to do so would involve a serious departure from the agreement with your Council of April 22, 1903, whereby this company is bound to establish a generating station for generating and distributing electrical energy, and that such station shall be established within the burgh of Dumbarton, I am to ask the views of your Council on the proposal. You will understand that by the agreement with your Council they are empowered at certain intervals to acquire the electric lighting undertaking from this company on the terms set out in the agreement, but if the proposals of the Scotch water-power promoters be adopted there will be no generating station within the burgh of Dumbarton—there will simply be a receiving, transforming, and distributing station, which will entail a very much smaller amount of capital expenditure. In this case your Council would be prevented from ever acquiring a generating station from the company, but they would be entitled to acquire the undertaking with its transforming station and mains, which would involve to your Council a very much smaller outlay of capital. The matter is thus one of much difficulty, requiring full consideration before anything definite is done. Another point which would have to be considered is that the water-power promoters are not in a position yet to deliver current, and to arrange terms with them would be to involve a greater delay than if the company carries out the original scheme. It would, therefore, follow if your Council approve of the suggestion, and providing the company are satisfied with the guarantees offered by the promoters of the water-power scheme, we would have to ask your Council for an extension of time, say six or nine months, for the completion of the works. I shall be glad at your early convenience if you will favour me with the views of your Council on this important matter."

PROVISIONAL PATENTS, 1904.

AUGUST 8.

17243. Improvements in and relating to fenders for electric cars and other vehicles. Frederick Reuben Keith, Old South-buildings, Boston, Massachusetts, U.S.A. (Complete specification.)

17248. Improvements in accumulators. John Byrom, 57, Renshaw-street, Liverpool.

17268. Improvements in or relating to electrical indicating apparatus for a range finder or the like. Thomas Kirkland and David Ling Capper, 111, Hatton-garden, London.

17285. High-tension current insulator. Franz Gustav Kleinsteuber, 52, Chancery-lane, London. (Complete specification.)

AUGUST 9.

17339. An improved electric switch. William George Heys, 51, Deansgate-arcade, Manchester. (The Meyrowitz Manufacturing Company, United States.) (Complete specification.)

17359. Improvements in apparatus for cleaning telephone and like switchboards. Frederick Louis Bronaugh and the British Compressed-Air Cleaning Company, Limited, 55, Chancery-lane, London.

17364. Improvements in means for preventing the breaking of an electric circuit. Edward George Paul Bousfield and the Ozonised Oxygen Company, Limited, 4, South-street, Finsbury, London. (Complete specification.)

17374. Improvements in wave telegraphy. Reginald Aubrey Fessenden, 24, Southampton-buildings, Chancery-lane, London. (Complete specification.)

17375. An improved terminal for electric cables. John Livingstone Sardy, 19, Holborn-viaduct, London.

17377. Wave indicator for wireless electric telegraphy. Gustav Engisch and the "Deutsche Erfinder-Genossenschaft," 26, Luisenstrasse, Berlin, Germany. (Complete specification.)

17378. Improvements in induction apparatus. Gustav Engisch and the "Deutsche Erfinder-Genossenschaft," 26, Luisenstrasse, Berlin, Germany.) (Complete specification.)

AUGUST 10.

4556B. Improvements in and relating to condensible elastic fluid generators and superheaters. Sebastian Ziani de Ferranti, 18, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Rule 9, Feb. 24, 1904.)

17393. Improvements in lifeguards for electric tramcars and motor-driven vehicles. Fred Butterworth, 4, Corporation-street, Manchester.

17399. Mechanical contrivance to control the tramline point and overhead trolley wire point. Francis Stephen Hollister, Sunnyside, Seldown, Poole, Dorset.

17423. Improvements in self-regulating dynamos. Heinrich Rosenberg and Emanuel Rosenberg. 111, Hatton-garden, London.

17430. Improvements in the electrolytic refining of copper. The Metals Corporation, Limited, and Sherard Cowper-Coles, 70, Chancery-lane, London.

17434. Improvements in and connected with electric lamps for medical purposes. Alfred Lloyd, 6, Lord-street, Liverpool.

17442. Improvements in electric controllers. William Harding Scott, 47, Lincoln's-inn-fields, London.

AUGUST 11.

17469. Improvements in electric alternate-current motors. Silvanus Phillips Thompson, Morland, Chislett-road, West Hampstead, London.

17478. Improvements relating to electric light fittings. James Marsden, 18, Southampton-buildings, Chancery-lane, London.

17483. A receiving system for wireless communications. Walton Harrison, 1, Broad-street-buildings, Liverpool-street, London. (Date applied for under Patents Act, 1901, Aug. 27, 1903, being date of application in United States.) (Complete specification.)

17484. A receiving system for wireless communications. Walton Harrison, 1, Broad-street-buildings, Liverpool-street, London. (Date applied for under Patents Act, 1901, Feb. 8, 1904, being date of application in United States.) (Complete specification.)

17493. An improved transmitter for electric telegraphs. Mejer Gerschkow Potiewski, 70, Chancery-lane, London. (Complete specification.)

17501. Improvements in "cow catchers" for electric and other cars. Walter Thomas Eastwood, 37, Chancery-lane, London.

17523. Improvements in liquid starting resistances for continuous-current motors. Frank Michael Lewis, Norfolk House, Norfolk-street, Strand, London.

17527. Improvements in commutators for dynamo-electric machines. Siemens Bros. and Co., Limited, and Hereford Berry, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

17532. Improvements in electric filters. Frank Benjmine Hinkson and Samuel Henry Hey, 18, Southampton-buildings, Chancery-lane, London. (Complete specification.)

21939A. Improvements in and relating to signalling through submarine and like cables. Sir Oliver Joseph Lodge and Alexander Muirhead, 18, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Rule 9, Oct. 12, 1903.)

Digitized by Google

17534. An improved construction of mechanical ear for trolley wires or the like. Thomas Ernest Raymond Phillips, 1, Broad-street-buildings, London.

AUGUST 12.

17553. Improvements relating to electric dynamos, motors, and the like. Edwin Ernest Kelsey, Cardium, Lingfield, Surrey.

17562. Improvements in printing telegraphs. James Dundas White, 50, Clanricade-gardens, London.

17595. Improvements in bends, elbows, and other angle pieces for electric conduits. Conduits and Fittings, Limited, David Musgrave Edwards, and Ernest Argyle Brown, 4, South-street, Finsbury, London. (Complete specification.)

17601. Improvements in rotors of alternating-current machines. Arnaldo Paolo Zani and Dick, Kerr, and Co., Limited, 18, Southampton-buildings, Chancery-lane, London.

17605. Improvements in insulating electric cables on the conduit system. George Edward Heyl-Dia, 6, Lord-street, Liverpool.

17611. Improvements in electric imitation candles. Messrs. Drake and Gorham, Limited, Bernard Mervyn Drake, and John Marshall Gorham, 66, Victoria-street, Westminster, London.

AUGUST 13.

17620. Improvements in or in connection with trolley poles (used on electric tramcars) for changing from one wire to another. John Bennett and Harry Grundy Crompton, Back-lane, Penwortham, near Preston, Lancs.

17621. Improvements in electric arc lamps. Veritys, Limited, and Frederic Stanhope Worsley, 11, Burlington-chambers, New-street, Birmingham.

17627. Improvements in regulation or graduation of the electric light of an incandescent lamp. Pedro Cardoso de Azenedo, 7, Tenison-street, York-road, Waterloo, London.

17632. Improvements in and connected with means for operating the points of electric tramways and the like, and also the overhead points or trolley switches, and in devices for actuating such operating means. Nehemiah Norris, 5, John Dalton-street, Manchester.

17639. Improvements in connection with electrolytic cells. William Thomson, the Royal Institution Laboratory, Manchester.

17650. An improved electrolytic rectifier. Max Büttner, 18, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Aug. 13, 1903, being date of application in Germany.) (Complete specification.)

17662. Wedge chock for securing a door in a partly open position and turning on electric light and bell. Julius August Schneppe, 77, Chancery-lane, London. (Complete specification.)

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Sept. 1, 1904.

1903.

10468. Sound reproducers or intensifiers applicable to phonographs, gramophones, telephones, and the like. Parsons.

17632. Manufacture of trolley poles and means for connecting them to trolley standards in trolleys used for electric tramcars or vehicles propelled by electric traction. Munro, Brecknell, and Rogers.

17633. Electricity meters. Harrison.

17643. Arrangement of steel magnetic armatures for electromagnetic pairs. Oerebotani and Silbermann.

18536. Means and apparatus for controlling electric motors. Imray. (Bullock Electric Manufacturing Company.)

20027. Electrical switches. Smith.

21669. Electro-deposition of metals upon aluminium. Creswick and Shaw.

21650. Connections or terminals for electric battery plates and other articles or structures composed of lead or lead alloys. Jackson.

25114. Coin-freed electric meters. Allan.

1904.

1414. Telephone relay. Gati.

2279. Trolley heads or collectors for electricity. Hadfield.

3211. Electric railway signalling systems. Bradley and Bowen.

7825. Twin sockets for electric incandescent lamps. Fairweather. (Benjamin Electric Manufacturing Company.)

8992. Telephone systems. Gleeson and Hamilton. (Date applied for under International Convention, May 1, 1903.)

9815. Method of charging storage batteries without the aid of auxiliary or special apparatus. Kraft.

10391. Electrical time switches for controlling railway barriers and the like. Neugebauer.

10837. Fuse-heads for electric blasting. Render.

10896. Electric motors. Johnson. (Elektrizitäts-Akt.-Ges. vorm. W. Lahmeyer und Co.)

13379. Mercury electric current interrupters. Schwedler.

13865. Means for transforming the energy of alternating currents. Weintraub. (Date applied for under International Convention, June 18, 1903.)

14521. Track sanders, brakes, and controller handles for electric tramcars and the like. Lintern.

14543. Thermo-electric couples. Bristol.

14544. Thermo-electric couples. Bristol.

14767. Nipple for use in connection with electrical conduit tubes and fittings. Hirst and Gunner.

15360. Electrolytic circuit breaker. Kölling.

15391. Surface-contact electric railway systems. Brown.

NOTES.

Penetrating Rays of Radium.—Mr. F. Paschen deals with this subject in the *Annalen der Physik*, demonstrating that the γ-rays from radium are like the β-rays in that they carry negative electricity with them. The former, however, are absorbed to a much smaller extent, and so the velocity of the γ-radiation is probably greater than that of the β-radiation. The highest velocity hitherto deduced for the latter has been about one-eighteenth that of light, and it is, therefore, possible that the case of electricity moving with the velocity of light may be realised in the γ-rays.

Another Use for the Telephone.—Our American contemporary *Telephony* describes the first long-distance telephone marriage that took place in New York State. The young pair, accompanied by a friend, went to the Iroquois Hotel in Buffalo, while a rural pastor, at whose church the bride had worshipped for some years, attended, with his wife, at the village telephone exchange. All the five were placed in communication, each being supplied with a receiver. The clergyman, recognising the voices of the principals, had no hesitation in pronouncing them husband and wife, the friend at Buffalo and the clergyman's wife being the witnesses. Another ceremony of the sort was performed in Kansas State.

London Engineering Degrees.—Now that the University of London has founded a degree in engineering (with a choice of mechanical, electrical, and civil subjects) without any residence or attendance qualifications, it is possible for the engineer, pupil, or apprentice who has not graduated at college to do so, as external student, by working during his leisure time. It also affords the students of colleges which are not part of any other university, the opportunity of obtaining a degree. The University College of Nottingham has been remarkably successful at the degree examinations recently held. The list of successful external students contained six names—no fewer than five being from the Nottingham college, and four of these took honours. The engineering laboratory equipment at Nottingham University College, already very extensive, is being added to and brought up-to-date for the coming session.

Automatic Shunt Regulator.—We learn from the *Zeitschrift für Elektrotechnik* that Messrs. Brown, Boveri, and Co. have recently patented an arrangement for automatically regulating the voltage of a dynamo running at variable speed on to a battery. The dynamo is shunt excited, and the amount of resistance in the shunt is regulated by means of a small electric motor mechanically coupled to the switch arm. This auxiliary motor has two field windings in opposition—the armature in series with one winding is connected across the battery terminals, whilst the other winding is in series with the main dynamo and battery. With normal current on the dynamo the two motor windings just neutralise one another, and the motor armature remains at rest. If, however, the current changes, the motor becomes excited in one or the other direction, and either increases or reduces the resistance in the main dynamo field. In this way the charging current is kept constant independently of the dynamo speed.

Good Performance by a Storage Battery.—The *Electrical Review* of New York chronicles a remarkable run on the part of an electric car manufactured by the Rhode Island Electromobile Company, which did the journey from Providence to Boston and back, a distance of over 100 miles, on one charge. The trip from Providence to Rhode Island was covered in 3½ hours, giving an average rate of 15 miles an hour. Three consecutive hills, covering a distance of nearly 1½ miles, were traversed in 10½ minutes. The current rose to 65 amperes, and on the heaviest part of the incline to 76 amperes for about half a minute on each hill. The average demand for the hills was from 50 to 55 amperes, the average on the level being from 22 to 25 amperes. The battery stood at two volts per cell at the end of the trip, so that the current remaining would probably have sufficed for a further 15 or 20 miles. The battery, composed of 42 cells, weighs 1,219lb., and the battery and carriage together a trifle less than 2,000lb.

Wireless Telegraphy Act.—The Postmaster-General has issued an order with reference to the Wireless Telegraphy Act, 1904, which states: "It is provided by the Act that a person shall not establish any wireless telegraph station or instal or work any apparatus for wireless telegraphy in any place in the British Isles or on board any British ship in territorial waters abutting on the coast of the British Isles except under and in accordance with a license granted in that behalf by the Postmaster-General. Wireless telegraphy is defined by the Act to mean any system of communication by telegraph, as defined in the Telegraph Acts, 1868 to 1904, without the aid of any wire connecting the points from and at which the messages or other communications are sent or received. Companies or persons requiring a license for any wireless telegraph station should make application to the Postmaster-General on or before Oct. 1, 1904. Forms of application may be obtained from the secretary to the General Post Office."

New Publications.—"Electro-Chemistry," Part I. (London: Longmans and Co., 5s.), by R. A. Lehfeldt. This is one of the series of text-books on physical chemistry edited by Sir Wm. Ramsay. It treats of the general theory of electro-chemistry, giving the relations between quantity of electricity and quantity of chemical action, and between E.M.F. and intensity of chemical action, reserving for a future volume the important applications of the theory to primary and secondary cells, electrolysis, and the solution of chemical problems. The author discusses the subject very thoroughly, and provides students with a highly useful treatise. "The Centrifugal Pump, Turbines, and Water Motors" (London: Simpkin, Marshall, and Co.; Manchester: The Technical Publishing Company; London and Manchester: John Heywood; 4s. 6d.), by C. H. Innes, M.A. This, the fourth edition, has been supplemented by descriptions of centrifugal pumps for high lifts, fans capable of producing considerable pressures, and other matters, and is profusely illustrated.

Model Telephone Exchange.—It is claimed that the new exchange to be erected at Columbus, Ohio, for the Citizen's Telephone Company will be unique in several respects. The building is to be as impervious to fire, from surrounding premises as well as from the interior of the exchange itself, as it is possible for a structure to be. With this idea in view, all window framework is to be of metal, and all glass, except on the Third-street front, is to be wire glass. The fourth storey, which is to contain the new telephone equipment, will have no windows at all except on the Third-street front, but will be lighted by skylights, which are to be constructed of steel frames and lighted through heavy wire glass. The floors of the building will be constructed on the Columbian fireproof system, which calls for the use of concrete. The entire framework of the building will be of steel, which is to be thoroughly fireproofed at every point. The partitions of the building will be of hollow terra-cotta tile, and the entire building will be equipped with the most modern appliances in the way of plumbing, heating, and ventilating. Brick and terra-cotta will be used exclusively for the exterior. The telephone equipment to be installed in this exchange will

Digitized by Google

be of the modern American type, by which operators are entirely dispensed with. It is expected that the exchange will be ready for use by December.

Nottingham Guild of Mechanical and Electrical Engineers.—A large party of this guild inspected the Digby Collieries at Kimberley last week. Arriving at the New London pit about 2 p.m., the visitors first inspected the machinery on the pit bank, which included the winding engines, Guival fan, dynamo-house, and conveyors, together with the screening apparatus. They then descended the pit, which has a depth of 220 yards, and after seeing the electrical pumps and stables, made their way to the coal face in No. 6 working. The journey from the pit bottom to the coal face and back was about 2½ miles, but the members were fully repaid for their trouble by the interesting features they witnessed. Upon returning to the bank the party were entertained to tea by the colliery officials, and afterwards a descent was made of the Digby pit, where the electrical coal-cutting machines were working. These, of course, were in great contrast to the more antiquated method seen in the New London pit. As this company has been using electrical coal-cutting machines with great success for a considerable time, the work was of much interest to the visitors. Upon again returning to the bank a vote of thanks was accorded to the colliery officials for the instructive and enjoyable time spent by the party.

Engineering Standards Committee.—We have received from the committee reports No. 7 and 8, which refer to "British Standard Tables of Copper Conductors and Thicknesses of Dielectric" and "British Standard Specifications for Tubular Tramway Poles" respectively. These documents are described as interim reports, but it should be understood that they are final as far as the tables and specification themselves are concerned, and are only of an interim character in so far that all reports are so regarded until such time as the final report, combining all specifications of the committee, is issued. The first of these reports states that the accepted standards of the Cablemakers' Association, the members of which rendered great assistance to the committee, were largely used as a basis for dielectrics. On the question of standards for conductors the report of the committee of 1900 and the work of Matthiessen were reviewed. The report in regard to tubular tramway poles recommends three classes of pole—light, medium, and heavy—the over-all length of each class to be 31ft., and the length of the telescope joint in the sectional poles to be 18in. The thickness of metal in any pole is not to be less than ¼in., and tests are prescribed for 5 per cent. of each class of pole a maker turns out. The committee express the hope that the standards laid down by them, which embody their own views and those of representative makers, "will be universally adopted by all engineers engaged in designing and installing electrical tramways throughout the British Empire."

The Destruction of Harmful Insects by Electricity.—In a recent number of the *Elektrotechnische Zeitschrift* particulars are given of some experiments carried out by the Russian Technical Society of Odessa on the destruction of insects, larvæ, and grubs on agricultural land by electrical means. A small dynamo was arranged on a wagon, drawn either by horses or by a petrol motor, and was driven by spur gearing from the wagon axle. Its terminals were connected through a Wehnelt interrupter to a sparking coil. The high-tension secondary of this coil had its negative terminal connected to earth through the wagon, and its positive terminal to a number of metal brushes fixed under the back part of the wagon and arranged to be vertically adjustable. A broad body of sparks was in this way made to pass from the brushes to earth, and killed any insects lying on the surface. It was observed that in the case of certain classes of insects—*e.g.*, beetles—the high-tension current acted on the nerve system first and disabled single limbs. In the case of grubs an electrolytic dispersion of the fluids seemed to take place simultaneously. Insects which were not killed instantly, but could still move one or more limbs after the passage of the wagon, died in a short time from the after effects. It is proposed to drive the wagon immediately behind the plough, as the turning up of the earth naturally exposes countless insects and larvæ. The practical value of the apparatus is hardly established yet, but the experiments are to be continued in the spring with a view to exterminating the turnip-fly found so plentifully all over Russia. The fight with these insects absorbed over 4,000,000 marks in the year 1901-2 in the Government of Kiev alone, and in South Russia an annual expenditure of from 10 to 20 marks per hectare is made for the same purpose. These figures show that the apparatus, which only costs about 5,000 marks, would soon pay for itself should it prove effective in practice.

The "Telagirl" System.—Our American contemporary, *Telephony*, describes a new business enterprise which has been inaugurated in Cleveland, Ohio, and which opens up an entirely new field for the development of the telephone industry as applied to everyday business affairs. The system is called the "Telagirl," and it consists of a plan by which business men may dictate their correspondence to a stenographer in a central office, the work being promptly executed and returned to the office of the subscriber. Private telephones are installed at the desk of each subscriber without expense, and enough stenographers are employed to take care of his work at any time he may call. The stenographer takes his dictation either by notes or on the typewriter as preferred, using his personal stationery, which is kept on files. The finished work is then enclosed, without folding, in a large envelope, sealed, and delivered by expeditious messenger service. The monthly statements rendered to clients of the company are of particular value, as they are itemised in every detail, thus forming a valuable reference index of correspondence to the business man. Complete privacy is secured, each stenographer having a small room of her own so that messages can be repeated back to the client without being overheard by others. In addition, a business man who has no one to leave in the office may have his telephone connected up with the "Telagirl" office when he steps out, inform the girls when he will be back, and leave instructions for anyone who may call him up. In that way all enquiries will be answered, and the new concern will take the place of an "office girl." Arrangements will also be made to take care of business at night, on Sunday, and at other odd times when employés of all offices are out. Graphophones will also be installed in the offices of those who desire them, and records of dictations will be called for by messenger. The charges will be moderate, and it is probable that the service will be broadened from time to time to take in other branches.

Live-Rail Dangers.—The Board of Trade has issued reports upon three fatalities resulting from contact with live rails. In one case, investigated by Major Druitt, a man named Patrick Flood was killed by contact with a live rail while trespassing on the Lancashire and Yorkshire Railway at Formby, where there are railings 4ft. to 5ft. high. The shock appears to have been accentuated in his case by the fact that his boots were almost worn out, so that he stepped on to the rail practically barefooted; and as it had been raining just previously all the conditions were conducive to a severe shock. Another trespasser who accompanied him survived the shock. There were

Digitized by Google

warnings at all level crossings and at places where people might be liable to trespass, such as alongside golf courses. Major Druitt, in exonerating the company, states, "As far as experience goes at present, it does not appear necessary to provide boarding for the live rail for the whole length of the line in order to protect the men employed in working the traffic, repairing the line, etc., or the passengers." The other two cases were investigated by Lieut.-Colonel von Donop, who reports in the case of Joseph Innes, a porter who was killed at Manors Station on the North-Eastern Railway, that where the body was found the rail was not protected, and he suggests that a guarding should be provided to all live rails where they pass through a station, as is done on the North-Eastern main line. The company is now taking precautions which Colonel Donop considers satisfactory. In the third case a lad climbed a 5ft. wall near St. Peter's Station on the North-Eastern Railway, and his bare feet came in contact with a live rail. Colonel von Donop is not prepared, at the present time at all events, to recommend the Board of Trade to call upon railway companies to guard their live rails continuously, but as the spot where this accident occurred is one at which trespass appears to have been common for some time past, he considers that some steps should be taken by the company to prevent access being so easily gained to the lines at that and any similar places. He also recommends that the guarding of the live rails be continued throughout the whole length of St. Peter's Station. Mr. A. P. Trotter, electrical adviser to the Board of Trade, concurs with these three reports. It will thus be seen that the company emerges scathless in the first instance, and practically so in the third, both accidents being, in fact, due to trespass; but in the second case the report attaches a certain degree of responsibility to the company. On the question of guarding the whole length of live rail, both inspectors, contrary to the opinion recently expressed by Dr. J. A. Fleming, consider that such a step is not necessary, though it is not without significance that this view is qualified by the words "at present." Apropos of live-wire dangers, an international congress is to be held at Paris in June of next year, under the auspices of the Association des Industriels de France Contre les Accidents du Travail, for the purpose of investigating apparatus for ensuring the greater safety of workmen employed on high-tension conductors. The device will be expected to indicate safely and plainly whether a conductor is alive or not. It must be applicable to direct and alternating currents of all voltages, and incapable of doing damage to itself, the conductor, or distribution system. A prize of £250 will be awarded to the exhibitor whose apparatus best satisfies the conditions, the system remaining the property of the inventor.

Electrical Progress in Canada.—The returns lately compiled by Mr. George Johnson, Dominion statistician, illustrate the advance in electricity made by our great Transatlantic colony. At the end of last year there were 647 miles of electrical street railways, of which 455 miles were single track and 192 miles double track. The aggregate mileage at the end of 1900 was 555 miles, so that the last three years have witnessed an increase of some 16 to 17 per cent. The distance run last year totalled 39,721,153 miles, against 36,711,130 in 1902, and 34,547,975 in 1901, the passengers numbering 167,703,958, 145,609,993, and 132,885,258 respectively. The paid-up capital stood approximately at £6,000,000 last year, £5,200,000 in 1902, and £5,000,000 in 1901, the gross earnings for those years being £1,620,275, £1,430,397, and £1,309,097, against gross expenditure of £1,045,579, £863,435, and £770,684 respectively. An analysis of the electric lighting returns shows that at the end of June last year the Dominion had 14,780 arc lights and 1,212,861 incandescent lights in use, which shows an increase in the aggregate of over 21 per cent. in 12 months. Since 1898 there has been an increase of 42 per cent. in the number of arc lights and 161 per cent. in incandescent lights. The chief user of electric light is the Province of Ontario, which has considerably more than half the total of arc lights and 47 per cent. of the incandescent lights. Thirty-four municipalities in the province supply themselves with electric lighting. Quebec stands second, but it is a long way behind Ontario, though during the period referred to it has shown a greater proportionate increase. In point of actual percentage of increase, however, British Columbia is at the head of the list, its increase of arc lights by 377 representing an increase of 82 per cent., and the increase of incandescent lights by 74,297 signifying an increase of 257 per cent. There were 324 electric lighting plants in the Dominion at the date of the returns, of which Ontario has no less than 203, Quebec being credited with 53. Statistics are given in regard to the manufacture of electrical appliances and supplies in establishment having five hands and over. From these it appears that during the decade 1891-1901 the invested capital of £350,000 at the former date increased by 246 per cent., the number of employés by 346 per cent., the wages by 434 per cent., and the output, which in 1891 was represented by finished products to the value of some £165,000, increased by 278 per cent. In addition to this, the smaller works, for which no comparative tables are available, have also made great strides, as far as can be ascertained. It is noteworthy that in the Canadian census for 1881 there is no mention of electrical industries. In the matter of telegraphy, Canada has 36,780 miles of line and 96,728 miles of wire. The messages dispatched during 1903 numbered 5,313,800, representing rather over a message per head of population. The decade 1893-1903 saw great telephonic progress. At the former date the Dominion had 44,000 miles of wire and 33,500 instruments, the messages sent during that year numbering 72,500,000. In 1903 the instruments had increased to 81,500 and the messages to 253,970,000, an increase of 144 per cent. in instruments and 250 per cent. in messages. On the population shown by the last census the Dominion has one instrument to every 65 persons. In electrical developments generally Ontario is the leading province, with Quebec a fairly promising second. The imports of electrical appliances and supplies during the last two years show heavy increases. The Dominion statistician concludes his report with a highly optimistic prediction for the development of electricity in all its Protean forms.

London's Telephone Service.—Some interesting information on the Post Office telephone arrangements in London is contained in the report of the Postmaster-General, issued last week. It states that two telephone circuits have been provided between London and Brussels, and are working in a satisfactory manner. The service between England and France, which is only limited by the electrical conditions, will be extended as they are improved. Experiments have been conducted during the year with a view to the establishment of telephonic communication between London and Holland. The results were such as to show that it is not at present practicable to construct at reasonable cost a cable which would enable direct telephonic communication to be established and maintained satisfactorily. The number of telephones in connection with the Post Office London telephone system increased during the year from 9,122 to 15,632; and additional subscribers are being connected at the rate of from 100 to 200 a

Digitized by Google

week. Three new exchanges have been opened during the year. The accommodation at the central exchange will be nearly exhausted in the course of the financial year 1904-5; and the construction of a second exchange with a maximum capacity of 18,000 lines is in progress. The working of the trunk system has been materially improved by the modifications introduced in the new switchboard. The length of the underground pipes laid in the London area on March 31 last was 1,146 miles, and cables containing 125,717 miles of wire have been provided, including 32,248 miles provided for the use of the National Telephone Company on rental terms. Owing to the great extent of the London exchange area, and the number of its local exchanges, the proportion of junction lines required is probably greater than in any other local exchange system in the world. The average cost of construction has increased since the last report from £18. 11s. 4d. per mile of double wire to £18. 16s. 10d. Including the cost of installation of telephone instruments and of exchange apparatus, the total cost of each subscriber's line has increased from £38 6s. 4d. to £41. 9s. 8d. This does not include the cost of the spare wires which are necessary for the maintenance of an exchange system in an efficient state. The account of receipts and expenditure shows a balance of £33,515 available for meeting the charge for interest on capital and for making provision for depreciation of plant. The capital expenditure to March 31 last was £1,514,300. It must, however, be remembered that a large part of the plant which has been constructed has not yet been brought into use, and is earning no revenue.

British Association.—The ceremony of conferring honorary degrees of the University of Cambridge upon some of the distinguished members of the British Association was performed on Monday afternoon with the customary formalities. The senate house was well filled with the friends of the candidates, and there was a good attendance of Doctors and Masters of Arts. Mr. Balfour, who was arrayed in scarlet, was received with loud applause. Sixteen members were admitted as Doctors in Science and one to the degree of Doctor in Letters. They were introduced by Dr. Sandys, the public orator, separately in a Latin address, enumerating, in concise and felicitous terms, the claims of each to recognition as an honorary graduate of the university. The following are brief references to some of the members selected for distinction, whom we have much pleasure in congratulating upon their well-merited recognition: Prof. Henri Becquerel, professor of physics in the Ecole Polytechnique, Paris, was welcomed as a distinguished member of the French Academy of Science, special reference being made to his remarkable discovery of the radioactivity of uranium. To recapitulate the achievements of Sir Wm. Ramsay and Sir Norman Lockyer would be to undertake a superfluous labour. Major P. A. MacMahon, late of the Royal Artillery, and formerly professor of physics at the Ordnance College, Woolwich, was one of the general secretaries of the British Association, and has published many works on mathematics. Prof. Arthur Schuster, professor of physics in the Victoria University of Manchester, worked at Cambridge with Clerk-Maxwell and Lord Rayleigh. Prof. Vito Volterra is one of the foremost mathematicians in Italy, and has composed works on the laws of light and theoretical dynamics. Sir David Gill will be remembered for his efforts in the cause of astronomy. The historic city of Heidelberg was doubly honoured in the persons of Profs. Bruehl and Albrecht Kossel, both distinguished in chemical science; and another representative from across the Channel was Prof. Paul von Groth, professor of mineralogy in the University of Munich, who has contributed more than any other Continental scientist to the general adoption of the crystallographic notation first proposed by Prof. Miller, of Cambridge. He founded, and has edited for 25 years, a journal on mineralogy and crystallography. We take this opportunity of stating that the association has accepted the invitation of the Corporation of York to hold its 1906 meeting in that city. It will be remembered that the first meeting of the committee was held in York. Again, the fiftieth anniversary of the founding of the association was marked by another meeting in York, and we gather that the mayor, in presenting the invitation to the committee, expressed the hope that the centenary also will be held in the Northern city.

Edison and the U.S. Patent Office.—The United States Assistant Commissioner of Patents has given his decision with respect to the charges brought by Mr. Thos. A. Edison against two officials of the Patent Office. The accusations had reference to the patent No. 738,110, granted on Sept. 1, 1903, to Mr. E. W. Jungner, and Mr. Edison alleged: "(1) That the examiners allowed the Jungner patent to issue when they knew, or should have known, that such issue was fraudulent; (2) that the examiners allowed the said patent to issue containing claims which they knew were unpatentable, and which, in fact, they had declared to be unpatentable, and which Jungner himself admitted were unpatentable; and (3) the examiners granted the said patent for an inoperative invention, which fact had been previously brought directly to their attention and acknowledged by them." The matter was referred by the Secretary of the Interior to the Commissioners of Patents, who held that the charges did not merit an enquiry. Mr. Edison appealed to President Roosevelt, who ordered a full investigation into the case. The case presented on behalf of the complainant was that Jungner based his claim on an application for a patent filed in the spring of 1899; that he tried two years afterwards by amendment to include certain chemical and mechanical features; that this was refused by the Patent Office on the ground that the amendments embodied new matter; and that in June, 1902, Jungner filed an application for a patent which was represented as being a division of his original application of 1899, but that this divisional application contained the same features of "new matter" as those which he had been unable to embody in his original patent by way of amendment. In his report on the case the assistant commissioner finds that "the disclosure in the patent is a different invention from that originally disclosed by him in his parent application, and, therefore, there is no basis in the original disclosure for the disclosure of his patent, and that, therefore, the examiners erred in allowing the patent as a division of the earlier application, as the patent is not, in fact, a division, for the reason that it not only contains new descriptive matter relating to its mechanical structure, but the invention disclosed is so changed as to be, in fact, a different invention from those originally disclosed in the earlier application; and that the patent, therefore, as to this new matter is effective only as to its new filing date." Judicial phraseology on the other side of the Atlantic appears to be not less involved than that associated with our own tribunals, but the practical effect of the finding is that the examiners erred in their judgment, though there was no evidence whatever to support the suggestion of *mala fides*.

Telephonic Progress in Japan.—The progress of the Japanese in regard to telephony is illustrated by the following report, recently issued by the United States Consul-General at Yokohama. Telephones were introduced into Japan in 1877, but those then in use were principally short-distance telephones, and they did not form

Digitized by Google

an important factor in business even in the large cities. At that time the telephone business was left to private enterprise, but later it was undertaken by the Government in connection with the telegraph, and it has since been under the control of the department of communications. The Government assumed the business during the fiscal year of 1890-91, and at June 30, 1891, there were two telephone exchange offices and 16 telephone call offices open to the public; the length of the lines was 122 miles; length of wires, 808 miles; number of subscribers, 343; and the number of messages which had been sent was approximately 264,988. For some years the increase was slow, but gradually the service became better appreciated, and at June 30, 1902, the number of exchange offices was 25 and the number of call offices 179, making 204 public offices, which during the next year increased to 318. At the latter date the length of the lines was 2,340 miles, the length of wires 105,770 miles, and the number of messages sent during the year was about 111,597,714. The number of subscribers at the end of 1902 was 24,887. In Tokio the ratio of the subscribers to the population is as 1 to 139, but in some cities it is much greater, being as 1 to 48 in Otaru. The telephone has now become so popular that the Government is not able to instal the instruments and connect the wires rapidly enough to keep pace with the demand, and in consequence the number of unconnected subscribers at the end of 1895 was 4,000, and six years later this had increased to more than 22,000. In 1902 the value of telephones imported was 97,022·82dol., of which more than half came from the United States; France, Belgium, and Germany ranking next in the order named. There has also been a constantly increasing excess of receipts over disbursements, and the profits received by the Government from telephones in 1901 amounted to 315,945dol. When the Government first took charge of the work naked overhead copper wires were used, but several changes have since been made to suit varying conditions. Underground cables are used on trunk lines in Tokio, Kyota, Osaka, Yokohama, Kobe, and Nagoya. Both iron and earthenware conduits have been tried, McRoy conduits having been imported from America to some extent. There are also some lead-covered underground cables, containing from 200 to 400 centres. Where the overhead wires still exist, they may be naked, as in most suburban lines; coated with zinc, as in districts where heavy snowstorms occur; or protected by rubber in places traversed by many electric wires. In some instances the same wires are utilised for both telegraph and telephone service. The circuits are on the duplex telephone system. Several types of instruments have been imported, and at present subscribers are furnished with either the solid-back or the Derville. The solid-back is usually provided for public offices and automatic call offices. Leclanché and Fuller batteries have been adopted, and the No. 12 arrester made by the Western Electric Company has superseded the Hibberd fuse apparatus.

Electricity in New Zealand—The enterprise undertaken by the Waipori Falls Electric Power Company, Limited, is the subject of an article in the *New Zealand Mining, Engineering, and Building Journal*. The company is constructing a power station at the Waipori Falls, with a transmission to Dunedin of 29 miles. The Waipori Falls consist of the whole volume of the Waipori River, the minimum flow of which has been found to be 80 sluice heads of water (4,800 cubic feet per minute). By means of dams this flow could be increased 50 per cent. The weir diverting the river into the flume is 75ft. long at Cust, 14ft. in height, and constructed on the rock-filled crib principle. The intake is in the form of a tunnel 25ft long, through a projecting spur of rock, the latter also giving an excellent key for the weir. The tunnel is 8ft. wide at invert, and the flume is 6ft. wide in the clear, built into the outlet end. The whole length of the aqueduct will consist of fluming, except when it passes through the tunnels. The flume rests upon a bench 10ft. wide, and 70 per cent. of the benching is in solid rock. When the flume passes gullies it is carried over on masonry piers. The flume has a uniform gradient of 8ft. per mile, and from experiments has been found to carry 117 sluice heads of water when running full, with a surface velocity of 7ft. per second. As only 80 heads are calculated on, a very safe free-board has been allowed. There is a space of 6in. between the top board and the transoms to enable an extra board to be put on when it becomes necessary to run 120 sluice heads in the flume. The total length of the aqueduct from intake to penstock is 1 mile 67 chains. The tunnels are six in number, ranging from 75ft. to 290ft. in length, and are through solid rock. The tunnels are somewhat larger than the flume in order to avoid lining. This timber is obtained from the company's own sawmill, which is driven by a Pelton water-wheel developing 25 h.p. The penstock is being constructed on solid rock foundations, and will be of concrete and masonry construction, 15ft. in depth. From the penstock two lines of pipes, 1,825ft. in length, will convey the water to the Pelton wheels. They will be equipped with all necessary air valves and air receivers, according to latest practice. At frequent intervals the pipes will be set on concrete saddles, and the whole will be covered, protecting them from sudden changes of temperature. The lower end of the pipe lines will be cemented into a rock tunnel through a spur which projects just above the power-house site. The hydrostatic head is 673ft., and as each pipe line will carry four sluice heads of water, the hydraulic head has been calculated as 665ft. Provision is being made for a third pipe line, to meet all increase of power demanded as the full volume of the company's resources are brought into requisition. Each pipe line will work two double-disc Pelton type wheels—that is, 20 sluice heads for each unit, passing through two deflecting nozzles, which will be regulated by Lombard type Q governors, electrically controlled from the switchboard. Each wheel will be mounted on opposite ends of the shaft of a 1,000-kw. generator, which will deliver at the power-house 1,333 h.p., and as 80 sluice heads will provide power for four units, the total power delivered in the power-house will be 4,000 kw., or 5,332 h p. The power-house will be erected on a natural river flat at the foot of the pipe lines, well above flood level, and on a rock foundation. The structure has been designed for erection in reinforced concrete, and will be fireproof. The machinery in the power-house will consist of Pelton wheels, generators, exciters, step-up transformers, switching and measuring instruments, and all necessary accessories. From the power-house the electrical energy will be transmitted to the sub-station near Dunedin. A probable feature of the transmission line will be the use of towers in place of the usual pole. A simple tower 60ft. in height has been erected in the Dunedin railway station yard, and is a model of lightness, strength, and durability. The sub-station will contain the necessary plant for step-down transformers, and necessary apparatus for the control and measurement of the current in connection with the important work of distribution, which will take place from this point. The efficiencies of the various machinery and apparatus have been guaranteed as follows: pipe line, 98·5 per cent.; Pelton wheels at full load, 80 per cent.; generators, 95 per cent.; step-up transformers, 97 per cent.; transmission line, 94 per cent.; step-down transformers, 98 per cent. From this it is calculated that some 4,100 e.h.p. will be available for distribution in Dunedin.

ELECTRICITY FROM WATER POWER.*

BY A. A. CAMPBELL SWINTON.

It should be gratifying to our national pride to know that probably the very earliest example of the production of electricity by means of water power on a practical scale, and its transmission to a distance, was the installation put up for the purpose of lighting at Cragside, Northumberland, by the late Lord Armstrong in the year 1882. This plant, which was still in daily use in 1884, when the author saw it in operation, consisted of a Siemens continuous-current dynamo, which was driven by means of a belt off an 8-h p. water-turbine operating with a fall of 30ft., the electricity, which was delivered at 90 volts pressure, being carried by bare overhead wires attached to porcelain insulators on poles to the house, about a mile distant. It is an interesting fact that when the installation was first put to work it was designed to operate with only a single wire, connection being made to the hydraulic power pipes at the one end and to the ordinary household water-pipes at the other, the earth being expected to form a sufficient return in the manner employed in telegraphy. This plan, which was adopted on the advice of the late Sir William Siemens, was found to be quite ineffective, as, owing to the low voltage employed and the exceedingly rocky nature of the ground, no useful amount of electricity could be transmitted, until the earth return was done away with and a second metallic conductor substituted.

Though this 22-year-old English example of electricity developed by water power and transmitted to a distance was, as already mentioned, probably the first such installation in existence in the world, the great development of such installations has, up to recently, taken place almost exclusively abroad. No doubt, up and down this country a very considerable number of small electric plants operated by water power have been put up for private house lighting and such like purposes, and there are even towns—such as, for instance, Salisbury and Keswick—where water power has for long been employed to assist steam power for electrical production for public and private lighting, the water power being in these instances found of great value for the purpose more especially of maintaining the supply during the periods of minimum load. A few hundred horse-power will, however, probably cover the whole of the plants of this character at present running in Great Britain, which is an altogether insignificant amount compared with the much larger corresponding figures for the continents of Europe, America, and other countries.

To obtain accurate statistics as to the amount of water horse-power at present employed for electrical production throughout the whole world is a very difficult matter, as in many countries no figures are available, while in others such as are obtainable are not up-to-date.

The following table, giving an aggregate horse-power of nearly one and a half millions, comprises all the hydraulic electricity works of which the author has been able to obtain particulars. He has, however, no doubt that there must be many others in existence to which he has not been able to find any reference; while again, in the case of a number of the installations which have been included, the horse-power now employed is greater than that in use at the time that the statistics were made out.

WATER-POWER ELECTRICITY INSTALLATIONS.

	Horse-power.
United States of America	527,467
Canada	228 225
Mexico	18,470
Venezuela	1,200
Brazil	800
Japan	3,450
Switzerland	133,302
France	161,343
Germany	81,077
Austria	16,000
Sweden	71,000
Russia	10,000
Italy	210 000
India	7,050
South Africa	2 100
Great Britain	11,9.6
Total horse-power	1,483 330

* Paper read before the British Association at Cambridge.

It, therefore, seems reasonable to suppose that the total amount of water power actually used for electrical production throughout the world at the present time must exceed 2,000,000 h.p., which is about double the total steam power at present devoted in Great Britain and Ireland to the same purpose.

It is interesting to calculate what would be the amount of coal required to produce this large amount of horse-power were it generated by steam-engines in the ordinary way. In other words, what is the saving of coal that the adoption of this amount of hydraulic power entails. Many of the hydraulic plants, particularly those which are used for chemical processes, operate at full power continuously night and day, but others work for shorter hours. Assuming, however, that the whole 2,000,000 h p. is in use for 12 hours per diem—in other words, is employed on the average with what engineers call a 50 per cent. load factor—and assuming, as is reasonable, that were the energy produced by means of coal, at least 3lb. of this fuel would be required on the average per horse-power hour, we get 5·86 tons of coal per horse-power year, or 11,720,000 tons of coal saved annually on account of the two million water horse-power utilised. Though this may appear a large figure, it amounts to less than 2 per cent. on the total output of coal in the world, which, on the average of the last five years, was 632,000,000 tons per annum. Assuming, however, an average cost of coal of 10s. per ton, this 11,720,000 tons represents £5,860,000 yearly, an amount which it would take over £100,000,000 of capital earning 5 per cent. per annum to provide.

Apart from mere magnitude, many of the more recent examples of hydro-electric engineering abroad, especially in America, are interesting by reason of the enormous distances over which the electric energy is being economically transmitted, and the very high electric pressures that in numerous cases are being successfully employed.

The longest distance over which transmission has so far been commercially effected is probably the 232 miles of line belonging to the California Gas and Electric Corporation, which stretches from the de Sabla power-house, *viâ* Cordelia, to the town of Sausalito, which is situated on the opposite side of the Golden Gate Straits from the city of San Francisco. What this transmission means will be realised when it is stated that the distance covered is about equal to that which separates Cambridge from Newcastle-on-Tyne. The same Californian company also owns the Colegate and Oakland transmission line, which runs 142 miles from the Colegate power-house, where 14,000 h.p. is developed from a head of water of 702ft.

Another very long line is that which reaches from the electric power-house *viâ* Stockton and Mission San José to San Francisco, a distance of 147 miles, over which 10,000 h.p. is being delivered regularly. This line belongs to the Standard Electric Company, who have 217 miles of power line, with a capacity of 27,000 h.p. in operation. The voltages employed, as is to be expected having regard to the distances covered, are very high, ranging from 55,000 to 67,000 volts, 60,000 volts being apparently the standard figure for many recent installations, of which the following are some examples:

PLANTS RECENTLY INSTALLED BY THE STANLEY ELECTRIC MANUFACTURING COMPANY, PITTSFIELD, MASSACHUSETTS.

Name.	H.P. capacity.	Voltage.	Transmission distance. Miles.	Head of water.
Quanajuato Power and Electric Company, Mexico	8,000	60,000	101	300ft.
Washington Water Power Company, Spokane	12,000	60,000	110	68ft.
Kern River Power Company, Los Angeles, California	16,000	67,500	110	—
Pierce Company	26,000	55,000	40	—
Mexican Light and Power Company, Mexico	—	60,000	110	1,500ft.
Winnipeg General Power Company	10,000	60,000	60	40ft.
Canadian Niagara Power Company	—	60,000	93	—
Electric Development Company of Ontario	—	60,000	93	—

For these particulars the author is indebted to Mr. C. C. Chesney, chief engineer of the Stanley Electric Manufac-

Digitized by Google

turing Company, who have recently installed these and numerous other similar plants.

Mention should also be made of the 50,000-h.p. and the 125,000-h.p. plants for the Canadian Niagara Power Company and the Electrical Power Company of Ontario, contracted for by the Canadian General Electric Company, both of which will employ pressures ranging up to 60,000 volts; while to pass to another quarter of the globe, the Cauvery Falls electric power scheme in India has now been at work for over two years, and transmits 5,000 h.p. to the Mysore gold mines, a distance of 92 miles, using a pressure of 35,000 volts.

Turning now to the British Isles, the only large-scale plant for the production of electricity by water power at present in operation in this country is the well-known installation of the British Aluminium Company at Foyers. This installation, which was originally designed by the late Mr. Birch and carried out by Mr. W. Vaux Graham, has been at work ever since the year 1896, and the whole of the power is employed for electrochemical purposes on the spot. A small percentage of the power is utilised for the production of calcium carbide, but the bulk is, and in the near future the whole of the power will be, used for making aluminium. At present the gross horse-power of the plant is 7,000 h.p., but plant for a further 2,000 h.p. is at the present moment being installed, and will be working in about a month's time.

The water is derived from the River Foyers, which has a catchment area of upwards of 100 square miles. Storage is effected by means of two lakes, which have been joined together by the raising of dams and embankments, the result being a continuous lake of about 5½ miles long by about half a mile in width. The storage thus obtained is sufficient to run the entire plant continuously day and night for about 50 days.

From the River Foyers the water is first passed through a tunnel 8½ft. in diameter, cut through the solid rock, to the penstock chamber, from which the water is delivered by separate cast-iron pipes to the turbines, which are installed on the shore of Loch Ness, and into which the water is finally discharged, the available head of water being 350ft.

The British Aluminium Company have obtained parliamentary powers for a further large water-power installation on Loch Leven. It is their intention to commence immediately the development of this scheme, which is capable of giving 17,000 gross horse-power. The reservoir is artificial, and will contain about 150 days' storage of the full power, the head of water at the turbines being 964ft. It is anticipated that the whole of this power will also be taken up in the manufacture of aluminium on the spot, no distant transmission being, at present, at any rate, contemplated.

Another interesting water-power scheme of considerable dimensions is at the present moment being developed in Wales by the North Wales Electric Power Company, who have obtained parliamentary powers for this purpose. Their first installation is at present being erected under the superintendence of Messrs. Harper Bros., the company's engineers, and derives its power from Lake Llydaw, on Snowdon. This lake, into which runs the water from Lake Glaslyn, is about 1⅛ miles in length and about a quarter to half a mile in width. Its area is 5½ million square feet, and it derives its water from a catchment area of about 1¾ square miles, including the summit of Snowdon. Being in the track of the Atlantic depressions, this area has one of the heaviest rainfalls in Europe, amounting on the average to 180in. per annum. In 1903 it reached the phenomenal figure of 250in. The prevailing winds are from the sea, and the atmospheric moisture is driven up the sloping side of the mountain, and on being condensed at the summit is discharged in the form of rain or snow on the eastern side over Lakes Glaslyn and Llydaw. The fall of the year gives the wettest months, and it happens that the quantity running from the lakes in spring is averaged up by the snow melting on the sheltered eastern side.

By means of a dam about 100ft. in length, the level of the lake is to be raised 20ft. The water will be drawn from the lake by means of a tunnel 600ft. in length at a point 30ft. below the present level, or 50ft. below the level when the dams are completed, with the result that there will be sufficient storage for meeting a 90 days' drought. The total fall utilised will be about 1,150ft., and the total horse-power available, on the basis of a nine hours' working day, is calculated at 8,200. The first installation consists of two steel pipe lines and four 1,000-kw. sets, each consisting of a double tangential waterwheel coupled to a three-phase alternator giving 11,000 volts at 40 periods per second.

The company will develop the full horse-power of Lake Llydaw before proceeding further, but they have also acquired a further water power at Llyn Eigiao, in the Conway Valley, where a fall of 800ft. is obtainable, and where it is calculated there will be nearly twice as much horse-power available as there is at Llyn Llydaw.

One of the first objects of the North Wales Electric Power Company, as soon as their installation is completed, will be to supply energy for the working of certain light railways which they control in the district. It is, however, in addition, intended to supply electric energy throughout a large area, comprising the whole of the counties of Carnarvon, Merioneth, and Anglesea, and also a portion of the county of Denbigh.

Three-phase currents are to be used, and the transmission lines will be of bare copper wires, ·324in. in diameter, carried on insulators triangularly placed on wooden poles. A large proportion of the transmission lines will be carried along the track of the above-mentioned light railways. Lines are to be laid to the principal slate quarry districts of Nantlle, Llanberis, Penrhyn, and Festiniog, where a considerable demand for power exists. The distances from the power station to these places range from six to twelve miles.

The latest water-power electric scheme in the United Kingdom is that of the Scotch Water-Power Syndicate, who have by agreement obtained from Lord Breadalbane and the trustees of the Colquhoun estate of Luss important water-power concessions. These agreements have been negotiated by Mr. E. Ristori, who, it may be mentioned, was one of the original founders of the Falls of Foyers installation, while the engineering and electrical details have been worked out by Mr. William Vaux Graham and the author.

The first power that it is proposed to develop is one connected with Loch Sloy, which is situated some five miles north of Tarbet, on the side of Ben Vorlich, between Loch Long and Loch Lomond. Loch Sloy, which is situated some 757ft. above Loch Lomond, which, in turn, is some 26ft. above the sea-level, is fed from a catchment area of about 3,801 acres, which includes one side of Ben Vorlich, which, with its 3,092ft., is one of the highest mountains in Scotland. The district has the very heavy rainfall of some 74in. per annum, of which it is calculated that 60in. will be collectable.

A dam will be constructed at the eastern end of the loch, which will raise the height of the latter by some 60ft. This will impound some 240 million cubic feet of water, capable, with a calculated net fall of 700ft. to Loch Lomond, of maintaining some 6,000 e.h.p on a 25 per cent. load factor for the maximum possible periods of drought, which are calculated at 100 days.

From the loch the water will be taken in the first instance along an open conduit 3,650 yards in length, which will follow the contour line round Ben Vorlich till a point is reached almost immediately above the position where the power-house will be constructed on the shore of Loch Lomond at a spot called Inveruglas. From the end of this conduit to the power-house the water will be coveyed in steel pipes, the length of the pipe line being about 600 yards and the height of fall 700ft.

From the power-house an overhead transmission line is to be constructed in duplicate for the purpose of conveying the electric energy to the industrial areas of the Vale of Leven and the Clyde, which comprise the towns of Dumbarton, Helensburgh, Renton, and Alexandria, and includes shipbuilding yards, engineering and dye works, calico printing works, and factories of various descriptions, many of whom have already intimated their desire to be supplied. The transmission line, for which private wayleaves have been obtained throughout, will be overhead on poles, starting from the generating station at Inveruglas, and continuing

Digitized by Google

across country for a distance of 22 miles to a sub-station which will be situated at Renton, about mid-way between Dumbarton and the foot of Loch Lomond, in the centre of the Vale of Leven industrial area. At this sub-station the voltage will be reduced from the 40,000 volts which it is proposed to employ for the long overhead transmission to some 6,000 to 10,000 volts, it being the intention that the distribution from the sub-station to the various works shall be underground.

The following are the efficiencies which it is calculated will be obtained:

	Full-load efficiency. Per cent.
Open conduit Pipe line Turbines	75
Three-phase generators	94
Step-up transformers	97
High-tension transmission line	93
Step-down transformers	97
Underground distribution (say 6,000 volts average)	95
Total efficiency	58·6

This is on the assumption of the energy being delivered to customers at 6,000 volts. If, as is probable in most instances, it will be delivered at lower voltages, there will be a further transformation, the efficiency of which will be 95 per cent. in the case of transformation in pressure only, and 86 per cent. in the transformation of continuous current, making a total over-all efficiencies: 55·6 per cent. for three-phase current delivered, and 50·3 per cent. for continuous current delivered.

So soon as a market has been found for the total power procurable from Loch Sloy, it is intended to utilise a further water power—for which the rights have also been obtained—at Ardlui, about two miles further up Loch Lomond. This power is also fed by a small loch with an available fall of 800ft., the horse-power obtainable being about half that available at Loch Sloy. The Scotch Water-Power Syndicate have, in addition, obtained the rights to still further water powers on the Breadalbane estate that exist further north, and these will be utilised as soon as the demand for power justifies the capital expense. It is because of these additional powers, which will considerably extend the length of the transmission, that it is proposed from the start to employ so high a pressure as 40,000 volts.

It is estimated that the total cost of the Loch Sloy scheme, including the transmission line and the distribution to the various factories, will not exceed £200,000, which, on a basis of 5,000 h.p. delivered, works out at about £40 per horse-power, everything included. Seeing that many of the existing electric generating stations worked by steam have cost almost this amount for land, buildings, and generating plant, this does not appear to be an excessive figure, and it may be pointed out as an interesting fact that the 20 miles of overhead transmission line only accounts for some £24,000, or about 12 per cent. of the total expenditure. This, coupled with the fact that the calculated loss on the transmission line at full load will only amount to about 7 per cent., and the step-up and step-down losses to another 6 per cent., making 13 per cent. in all, will give some idea of the extent to which the length of the transmission line is but a comparatively unimportant factor in schemes of this description. It may be pointed out, further, that the above-mentioned line loss of 7 per cent. is upon the basis of only one of the two duplicate transmission lines being in use. When both are employed the line loss will be reduced to $3\frac{1}{2}$ per cent., and the total transmission loss at full load will be only a little over 10 per cent.

The main transmission will be on the three-phase system over two sets of three copper conductors, each about $\frac{3}{10}$in. in diameter, the possibility of conveying as much as 5,000 h p. over a distance as great as 22 miles with only $3\frac{1}{2}$ per cent. loss by means of such comparatively small wires being, of course, due to the high pressure employed. Indeed, using pressure as high as 40,000 volts, when it is a matter of transmitting comparatively small amounts of power, as, for instance, the 600 h.p. or thereabouts that under the present scheme it is expected will be required for the supply of the town of Helensburgh, the interesting point arises that the minimum size of conductor allowable is limited, not by electrical conditions, but by considerations of mechanical strength.

On the main transmission line the conductors will be carrried at a minimum height of 40ft. from the ground, while at all crossings over roads they will be enclosed in a wire cage to meet the Board of Trade requirements for ensuring public safety.

The application of water power in the United Kingdom can, of course, never attain the dimensions that it has already reached in America and elsewhere; still, the above brief account of what is at present being done in Scotland and in Wales shows that there are possibilities even in this old country of which till recently but few were aware.

As regards the economies of electrical generation by water power, no general rule can, of course, be enunciated, and every case must be dealt with on its merits, according to local circumstances. This, notwithstanding it is possible to give an indication of what is generally involved, having regard more especially to the fact that with water power, as a rule, interest on capital plays a much greater part in determining the cost than do labour or upkeep.

Avoiding, on the one hand, small powers where the costs are likely to be abnormally high, and on the other very large powers such as we do not possess in this country, it may be taken generally that interest on capital, depreciation, upkeep, and working expenses in this country will amount to about 12 per cent. on the capital expenditure.

On this basis it is easy to see that to be economically sound the capital involved must not exceed $8\frac{1}{2}$ times the annual price which can be got for the whole of the energy. For instance, if 5,000 h.p. is available for sale, and £6 can be got for each horse-power on the average per annum, the capital involved must not exceed £52 per horse-power, or £260,000 in all.

To conclude, it has been said that the greatest benefactor to the human race is he who makes two blades of grass to sprout where only one grew before. On this principle, the utilisation of natural water power is obviously to the public advantage. When mechanical or electrical energy is generated by the burning of coal, it is a matter of the consumption, not of interest, but of capital. On the other hand, every water horse-power that is put to use is something added, mundanely speaking, for all time, to the permanent resources of mankind.

Discussion.

Sir W. H. Preece said, in opening the discussion, that the use of water power was largely one of finance; for instance, Prof. George Forbes had worked at a scheme for using the water power of the Nile and transmitting it to Cairo. It was found on investigation that it would be cheaper to ship coal from Cardiff to Cairo and produce the electrical power from this coal.

Mr. C. Hawksley pointed out the difficulty in all water-power installations within the British Isles due to the intermittent nature of the water supply.

Mr. W. M. Mordey said that last year he had investigated several power schemes for Natal, but had found that in all cases the cost of supply from the water power available would be more than if coal was used. Switzerland was an exception as regards regularity of water power available, owing to the glacier storage. The water in summer was actually greater than in winter, as the lake level at Geneva was much higher in the summer, when the ice was melting. Even in Switzerland steam had to be used as a stand-by in certain cases, owing to the frost in winter reducing the water power available.

Mr. McClellan remarked that, although Buffalo was only 18 miles away from Niagara, a steam stand-by was used in Buffalo to get coal for the peak. He was interested in Mr. Campbell Swinton's proposed supply of power in Dumbarton from Loch Lomond. The price of coal in Dumbarton is only 5s. per ton, and hence the competition with the power consumer would be keen.

Mr. Campbell Swinton, in reply, quite agreed with the important financial considerations brought forward. He had gone carefully into the figures of the Loch Lomond supply. Their best consumer was at the present using gas, but he had no doubt that he could supply this consumer cheaper than he could produce power at present.

ENERGY LOSSES IN MAGNETISING IRON.*

BY W. M. MORDEY AND A. G HANSARD

That this subject has a good claim to the consideration of the engineering section of the British Association, will be admitted when it is pointed out that not less than 25,000 tons, perhaps as much as 50,000 tons, of coal are burnt every year in this country to keep alternate-current transformers magnetised.† This waste must be multiplied by at least three or four, if it is to include the alternating magnetising losses in dynamos and motors.

The magnetising loss is partly due to hysteresis and partly to eddy currents. When testing iron for electrical purposes, many engineers are satisfied to measure the hysteresis only, and for this purpose Ewing's well-known tester is generally used. This ingenious instrument, introduced by Prof. Ewing to avoid the slow and laborious test by the ballistic method, directly compares the torque produced by revolving a small sample between the poles of a permanent magnet, with that produced by samples, the hysteresis loss in which has been tested by a ballistic galvanometer. This instrument gives a result for one magnetic density only, and must therefore be used for other densities by reference to results otherwise obtained. These methods aim only at measuring hysteresis, which, as a cause of loss, is not more important than eddy currents. The determination of hysteresis is of great interest to physicists, but for engineering purposes what we want to know is the sum of the two losses at various densities and periodicities; how this total is made up is usually of minor importance.

These considerations led one of the authors in 1890, when faced with the necessity of getting iron for transformers of definite quality, to adopt the plan, previously advocated by Mr. Swinburne, of measurement of the total loss by a wattmeter, if possible under the actual conditions of working. For workshop convenience a fixed point of comparison was chosen, at which all iron was tested. This was stated as follows: "The loss in iron sheets or stampings ·014in. thick made up in the form of a transformer and tested by a wattmeter should be 0·38 watt per pound at a magnetisation of 2,500 B and at 100 periods per second."‡ At that time the custom was to order "best soft Swedish charcoal iron carefully annealed," but such iron varied in its losses under the defined conditions from little more than ·3 watt per pound up to about ·6, causing serious engineering difficulties.

Although further lamination was recognised as desirable, it was found to be difficult to get sheets thinner than ·014in. (0·35mm.), so that was adopted for all purposes. The low magnetisation of 2,500 B was chosen as a point for comparison, because it was desired to keep down the no-load losses and the heating of 100-period transformers. For lower periodicities, higher densities may, of course, be used.

The only manufacturers to take up this specification energetically were Messrs. Sankey and Sons, of Bilston, with whom an arrangement was made by which the price paid them was increased or reduced as the iron showed less or more than the standard loss.

A few pounds of iron were tested in this way out of each delivery, and the corresponding bonus or penalty ascertained. The result was that within a year large variations of loss had ceased, and it soon became possible to design transformers with something like certainty as to what the magnetising losses would be. This improvement in quality and regularity which affected the whole industry is mentioned here, because it is not generally known how much is due to the efforts of these manufacturers.

We have continued to use the wattmeter method as the only one that tells us what we want to know, and we advocate its advantages over any other plan. It has only one drawback, that it is necessary, or, at least, desirable, to use a rather large quantity of iron for the tests.*

The Curve I. (Fig. 1) is an average from the results of a great number of wattmeter tests made before 1898 in carrying out this arrangement.

Better iron is now obtainable. Fig. 2 shows the total losses at 50 and 100 ⌒⌣ for good ·014in. iron that can be got regularly. It will be seen that it loses about one watt per pound at 5,000 B, 100 ⌒⌣, and ·32 watt at 2,500 B. At 50 ⌒⌣ it loses one watt per pound at about 8,500 B. It is not safe to rely on getting better iron than this for large quantities, although occasionally better results are got in small quantities.†

The separation of hysteresis and eddy losses by calculation is based on the assumption that hysteresis varies directly as the periodicity, and as $B^{1.6}$, the latter or

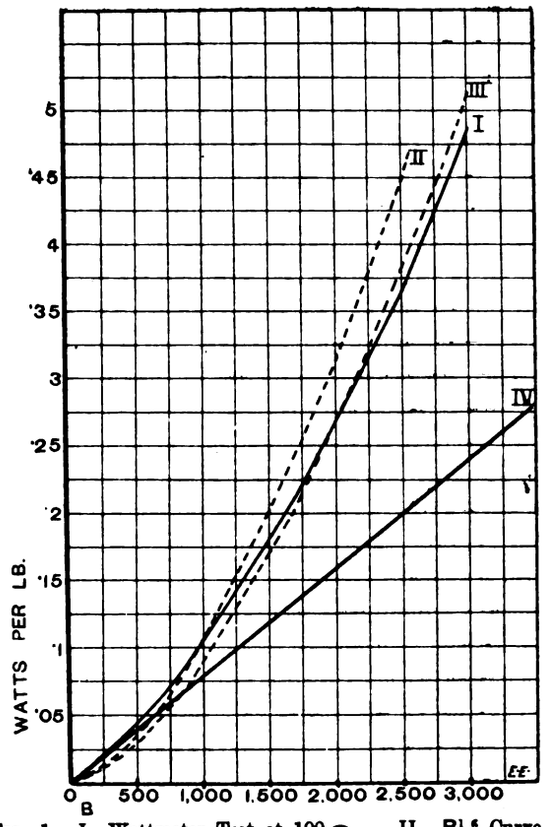

FIG. 1.—I., Wattmeter Test at 100 ⌒⌣. II., $B^{1.6}$ Curve through B 1,000. III, $B^{1.6}$ Curve through B 2,000.

Steinmetz ratio being the value which Mr. Steinmetz, working from Prof. Ewing's results and from observations

* Paper read before the British Association at Cambridge.

† Estimated as follows: Transformers in use, fully 300,000 kw.; average magnetising loss, 1·5 per cent. for 12 hours a day = 19,700,000 Board of Trade units a year, at 5lb. of coal per unit = 43,750 tons. Or to put it another way: at ·5 watt magnetising loss per pound of iron—a moderate estimate—each ton of transformer iron continuously used consumes 9,811 Board of Trade units a year, which at 5lb. a unit involves the consumption of 22 tons of coal.

‡ Watts per pound at 100 ⌒⌣ may be converted to ergs per cubic centimetre per cycle by multiplying by 1,700.

* These tests and those of the curves given in Figs. 2 and 4 have been made with a wattmeter designed some years ago by Prof. J. A. Fleming for the special purpose of such measurements. In this instrument, of the dynamometer type, every care has been taken to avoid the presence of any metal likely to cause eddies, and to avoid errors due to self-induction or capacity in the circuit of the pressure coil, which consists of few turns, and is used in conjunction with a non-inductive resistance and a separate variable-ratio transformer. In order to increase the range of the instrument, the current in the pressure coil is varied, and is read by a separate Siemens dynamometer. This not only largely increases the range of the instrument, but also enables the same reading to be taken under two or more instrumental conditions. The E.M.F. was read by a Kelvin multicellular electrostatic reflecting voltmeter. The alternator used had practically a sine curve.

† It is often convenient to use an empirical rule even if it has no relation to physical realities. This may excuse our pointing out that most curves of total magnetising loss in iron are very closely satisfied by a division into two portions, one directly proportional to B, the other proportional to B^2. The Curve I. in Fig. 1 may be so divided by the straight line, IV. It is only necessary to remember that this line cuts the total loss of ·48 watt per pound at 3,000 B into two equal parts to construct the whole curve. A similar division will be found to apply to the curves of Fig. 2, which go through a much longer range. The points of equality in the two portions being 2,500 B for the 50 ⌒⌣ and 4,000 B for the 100 ⌒⌣, in both cases the point corresponding to a loss of ·32 watt per pound.

In order to show the similarity of a $B^{1.6}$ curve and a $B+B^2$ curve, Fig. 3 has been drawn, in which the curve marked with round dots is a $B^{1.6}$ curve, and that with crosses is a $B+B^2$ curve drawn through two points on the other curve (having abcissæ 3 and 6). The straight line is the B component of the $B+B^2$ curve.

of his own, found to express the relation between hysteresis and density. The eddy currents are always assumed to vary as the square of the magnetisation, the square of the periodicity, the square of the thickness, and inversely as the resistance of the iron. As the eddies in ordinary thicknesses of plates are by no means negligible, it becomes a matter of some difficulty to reconcile these assumptions with the facts, especially when the total loss curve is found to be a $B^{1.6}$ curve, as often happens.

For example, the Curve I. in Fig. 1 within its very limited range seems to show that the total loss increases with the density in a less ratio than $B^{1.6}$. The dotted curves, II. and III., represent $B^{1.6}$ values drawn through

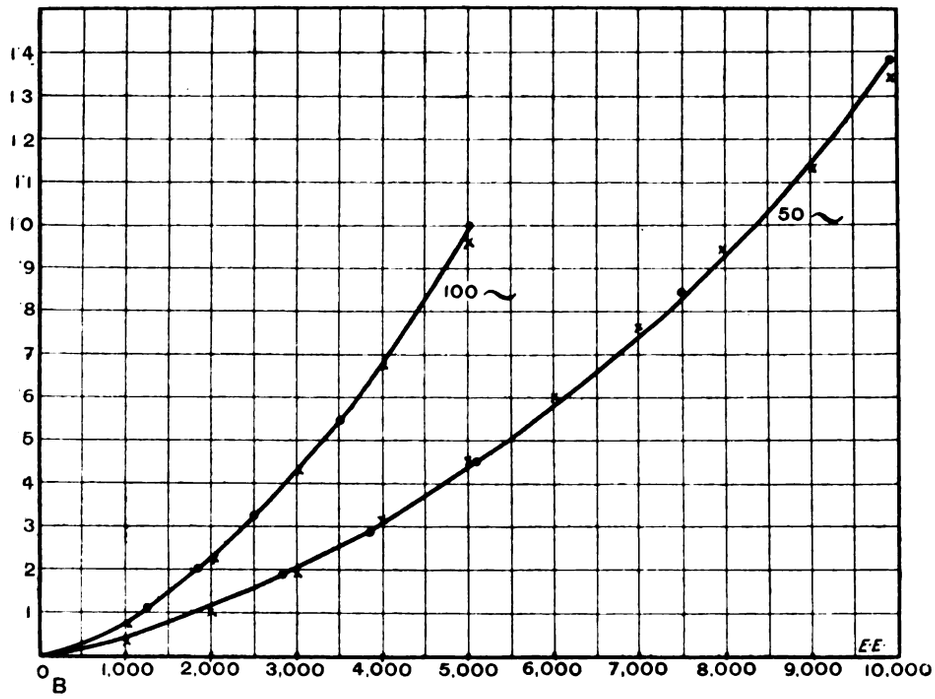

FIG. 2.—Magnetising Loss in Watts per Pound in Iron 0·014in. thick at 50 ~ and 100 ~.
• • Wattmeter tests. x x $B^{1.6}$ values.

1,000 B and 2,000 B respectively. Curve I. is inconsistent with the above assumptions, for if eddies varying as B^2 have to be added, the total losses should rise more steeply than the $B^{1.6}$ curve, instead of less steeply, as shown.

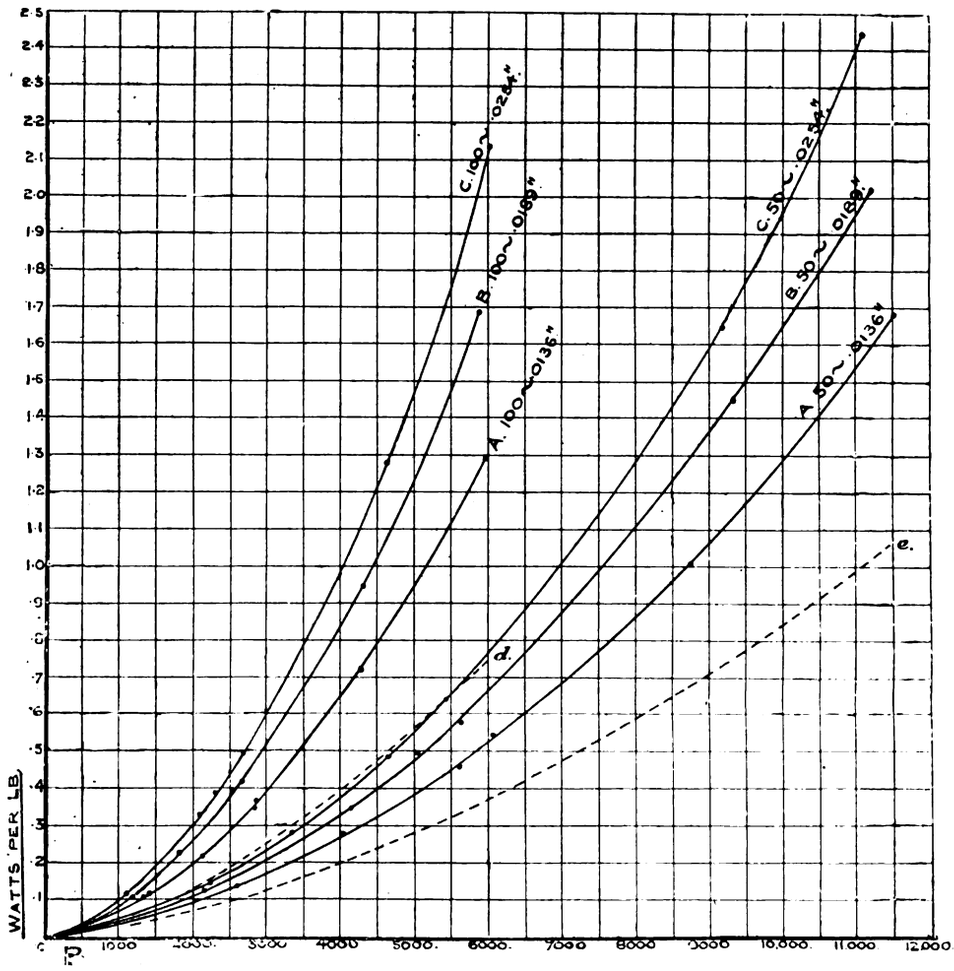

FIG. 4.—Magnetising Loss in Iron of different thicknesses at 50 ~ and 100 ~ ; *d* hysteresis at 100 ~ ; *e* hysteresis at 50 ~.

The curves of Fig. 2 afford another illustration of this difficulty. The round points on these two curves are the wattmeter readings. The points thus x are $B^{1.6}$ values

Digitized by Google

calculated from 4,000 B. It will be seen that these $B^{1.6}$ values correspond almost exactly with the total loss curves, and therefore no room is left for eddies on the ordinary assumptions for hysteresis and eddies. That eddies are present in a considerable amount is shown by reference to numerous ballistic tests of hysteresis of similar iron which are always much lower than the total losses of these curves. Further, the 50 and 100 ⌒ curves are not in the ratio of 1 to 2, as they would be if there were no eddies, and if hysteresis were proportional to the periodicity. In such cases as this, if we admit that the hysteresis is proportional to $B^{1.6}$, the eddies also must follow nearly the same law.

The authors find that the curves given in Kapp's "Transformers" (1896, p. 23), which are carried up to between 6,500 and 7,000 B, have the same characteristics with regard to $B^{1.6}$ curves as the authors' (Curve I., Fig. 1). Whilst we are all prepared for considerable differences in the amount of the losses in iron, even of the same thickness and make, it is disturbing to find such difference not only in the amount, but in the character of the curves; and it shows how necessary it is, with such a material as iron, to base conclusions only on a large number of different observations.

In order to examine the effect of increase of thickness of iron sheets, the authors have tested some transformer stampings made from sheets of three different thicknesses of the same quality of iron kindly supplied by Messrs. Sankey and Sons. The thickness of the three samples, A, B, and C, calculated from the weight, is given below. Gauging with a micrometer showed a variation of about ·001in. in the actual thickness of the plates. Samples of these plates were tested on a Ewing hysteresis tester by a very experienced experimenter, who obtained the results ·39, ·38, and ·40. Another experienced experimenter, on a different Ewing instrument, made the loss ·44 in each of the

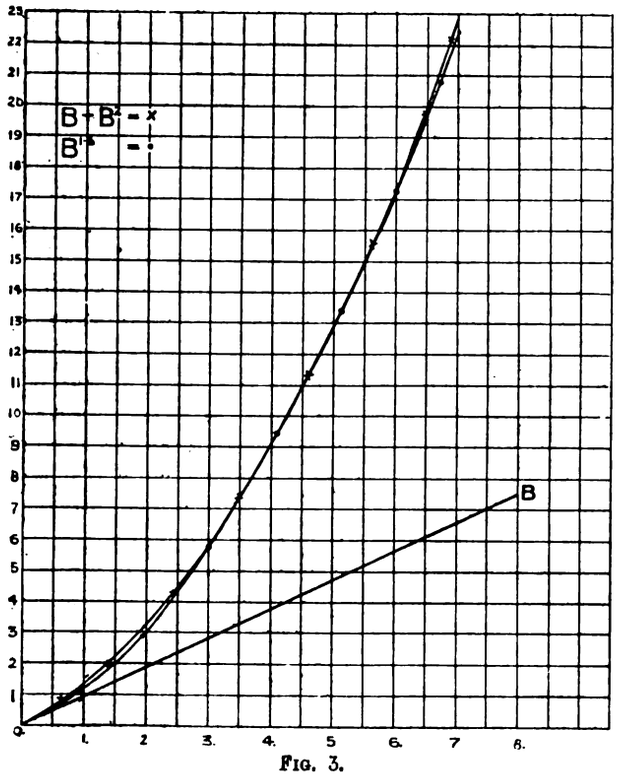

FIG. 3.

three samples. We have adopted the former figures for purposes of comparison.

	Thickness. Inch.	Mm.	Watts per lb. at 100 ⌒ 4,000 B.
A	·0136	·34	·39
B	·0189	·47	·38
C	·0254	·61	·40

The stampings were made up in transformer form, about 11·7lb. being used in each case, and wattmeter tests of the total loss were made at 50 and 100 ⌒, at six values of B in each case. After deducting the losses in the winding, the iron losses were found to be as shown in the six curves of Fig. 4, which, unlike those of Figs. 1 and 2, are all steeper than $B^{1.6}$ curves, and therefore do not present the same difficulty.

The following table, based on these curves, gives results for eddies and hysteresis at various densities. The hysteresis is based on the values ·39, ·38, and ·40 at 4,000 B, 100 ⌒ by the Ewing tester, the other values of hysteresis being calculated as proportional to $B^{1.6}$ and directly proportional to periodicity.* This procedure seems justified by the form

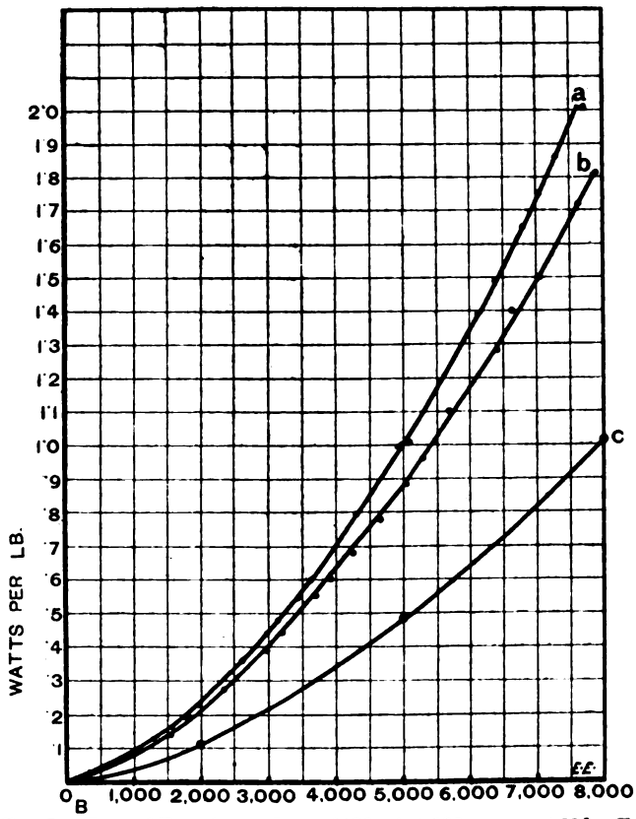

FIG. 5.—Tests of Transformer Iron (·0124in.) at 100⌒; *a* at 40deg. F. and *b* at 167deg. F. by wattmeter, *c* by ballistic galvanometer at about 70deg. F.

of these six curves. The total losses are by the wattmeter readings. The 10,000 B results are only for 50 periods, the 100 ⌒ tests not having been carried higher than 6,000 B.† Results at 2,500 B are worked out only for 100 ⌒. Judging from the thinnest sheets the iron is of excellent quality.

Losses in Watts per Pound of Iron at 50 and 100 Periods.

Thickness.	Hysteresis. 100 ⌒	50 ⌒	Total loss. 100 ⌒	50 ⌒	Difference due to eddies. 100 ⌒	50 ⌒	Percentage of eddies. 100 ⌒	50 ⌒	B.
A ·0136in.	·183	—	·285	—	·102	—	35·8	—	2,500
B ·0189in.	·179	—	·37	—	·191	—	51·5	—	2,500
C ·0254in.	·188	—	·44	—	·252	—	57·2	—	2,500
A ·0136in.	·39	·195	·635	·26	·245	·065	38·6	25	4,000
B ·0189in.	·38	·19	·83	·322	·45	·132	54 2	29·8	4,000
C ·0254in.	·40	·20	·99	·37	·59	·17	59 5	46	4,000
A ·0136in.	·746	·373	1·30	·52	·554	·147	42·6	28·3	6,000
B ·0189in.	·727	·363	1·76	67	1 03	·307	54·5	45·8	6,000
C ·0254in.	·766	·383	2·12	·76	1·35	·377	63·7	49·6	6,000
A ·0136in.	—	·845	—	1·33	—	·475	—	35 8	10,000
B ·0189in.	—	·822	—	1·64	—	·818	—	50	10,000
C ·0254in.	—	·867	—	1·95	—	1·083	—	55·5	10,000

These results show very clearly that even with these thin sheets and moderate densities the eddy loss is of the same order of importance as the hysteresis.

* The two dotted curves in Fig. 4, *d* and *e*, show the hysteresis loss, assumed to vary as $B^{1.6}$, for 100 ⌒ and 50 ⌒ respectively, taken from the mean of these three values—viz., ·39 watt per pound at 100 ⌒.

† An objection may be made to this analysis that the results obtained with the Ewing tester—namely, ·39, ·38, and ·40—on samples weighing only about ½ oz. each are possibly not representative of the average of each of the 11·7lb. samples tested by the wattmeter. We admit this, but that is one of the uncertainties inseparable from the small scale of the operation. It may also be objected that the higher and uniform value of ·44 got on the same three test pieces by another experimenter would alter the figures somewhat. That is true, but the main broad results and conclusions would not be appreciably affected.

Examining the result to find what light they throw on the assumptions that eddies are proportional to the square of the thickness, the square of B, and the square of the periodicity, we get the following values:

	6,000	1	3·58
Average			3·46

These three comparisons lead to the following conclusions: For the ·0136 and ·0189 sheets the increase is practically proportional to (thickness)²—that is, the loss with the latter is nearly double that with the former. But as between ·0136 and ·0254 the average increase is less than (thickness)² by about 30 per cent. It is about 2 5 instead of 3·5 times greater.

As regards the relation between B and eddies, the tests on the whole do not indicate any marked departure from the B² assumption. As regards periodicity, the averages show that the increase is as 1 to 3·46, instead of 1 to 4.

We suggest that the result showing that eddies increase less quickly than (thickness)² and (periodicity)² may be reasonably explained by assuming that the eddy circuits have self-induction. If this is so, it prevents the possibility of dealing with them simply by Ohm's law, as hitherto seems to have been the practice.

Effect of Temperature on Eddies.—It might be possible to ascertain the total eddies, and to separate eddies from hysteresis, by measuring the total loss at two temperatures, assuming hysteresis to be constant within the range of the temperatures, and comparing the result with the assistance of the ascertained temperature coefficient. Fig. 5 shows a wattmeter test made of some ·0214in. transformer iron (by Sankey) at 40deg. F. and 167deg. F. for this purpose, together with a ballistic galvanometer determination of the hysteresis of the same iron. The latter test was made without special reference to temperature, which, however, is believed to have been about 70deg. F. The iron was found to have a temperature coefficient of ·248 per cent. per 1deg. F. (reckoning from 32deg. F.) based on observation taken at 72deg. F. and 154deg. F.

The ballistic test was made at three points respectively—8,000, 5,000, and 2,000 B. It is important to note that these points lie on a $B^{1.6}$ curve, as do also the wattmeter curves of this figure. As in Fig. 4, the eddies bear a very large ratio to the hysteresis, being about 50 per cent. of the total loss at the higher values of B. The effect of change in temperature is very marked, the increase of 127deg. F. giving a reduction of total loss—at 7,500 B, for example—of 0·28 watt per pound = 14·4 per cent. of the total loss, or 27·3 per cent. of the eddy loss.

An examination of the curves at 40deg. and 167deg. F. shows that the eddy currents, at least at the higher densities, apparently increase rather more rapidly than the fall of the resistance, suggesting the possibility that the hysteresis decreases under working conditions at these higher values of B. The authors, however, only wish to put the experiment forward as a further proof of the importance of the eddies, and as possibly affording a means of useful investigation of the relation of eddies to hysteresis.

The considerable decrease in the total loss with rise of temperature must not be taken as a reason for working transformers hot—the increase of copper resistance would do much to counterbalance any saving in the iron. At one time the effect of continued heating at such a temperature as 167deg. F. would have been to cause a slow increase in the hysteresis, but this effect has now been overcome in this quality of iron, at least for such temperatures as this.

It may be thought that there is a remote possibility of explaining the increase of eddies—as judged by the curves of total loss—being less than the received theories would require, by assuming that there may be a decrease in hysteresis with B, as has been shown to take place under certain conditions by Prof. Baily's very interesting experiment, which lent support to Prof. Ewing's magnetic theory, and confirmed a prediction of Mr. Swinburne.* Such an explanation, however, would receive no support from our analyses, in which, on the whole, the eddy loss appears to be nearly proportional to B².

Although these results refer particularly to transformer conditions, they are applicable to a good deal of dynamo, alternator, and motor work, in much of which the periodicities are as high as for transformers, even for direct-current work, for instance, turbine-driven dynamos; a four-pole machine at 1,500 revolutions per minute works at 50 ~ per second. With such machines it is very necessary to work at as high B as possible, and under such circumstances the eddy losses are very large—especially as there is probably a greater tendency to eddies in dynamos than in transformers on account of the less even magnetic distribution in the former. Even in ordinary dynamos working at 8 to 16 ~, with about 15,000 or 16,000 B in the core and 20,000 B or more in the teeth, the eddy loss will be found to account for an appreciable proportion of the total loss. As to the practical aspect of the question of thickness, it has been already stated that it is difficult to get iron thinner than ·014in. (·35mm.). Perhaps a practical limit will be reached at ·01in. (·25mm.). This would save nearly half the eddies, as compared with ·014, and in some cases this would justify a considerable increase in the price of the iron. For example, the saving in one ton of ·01in. iron used continuously at 15,000 B 50 ~, as compared with ·014in., would be more than 10,000 Board of Trade units a year. There is, however, some ground for believing that on the average the hysteresis loss with a given iron is rather higher when it is rolled very thin. The difference, however, is not likely to be so much as to counterbalance the considerable saving in eddy loss under many practical working conditions. Until some iron or steel has been discovered having a higher specific resistance combined with high magnetic qualities, the only way to reduce eddies is to use as thin iron as possible.

The authors would summarise their conclusions as follows: (1) in determining the magnetic quality of iron sheets, eddy-current losses, though often neglected, are by no means negligible, and are often as important as hysteresis; (2) the simple laws generally assumed to be followed by hysteresis and eddies are found, as often as not, to be rather widely departed from; and (3) consequently, with such a variable material as iron, the only satisfactory method of predicting losses is to make wattmeter tests of samples, as nearly as possible under the working conditions.

The authors wish to thank Mr. L. W. Wild, of the Westminster Electrical Testing Laboratory, for his able assistance in some of the experiments.

ON LARGE-BULB INCANDESCENT ELECTRIC LAMPS AS SECONDARY STANDARDS OF LIGHT.*

BY J. A. FLEMING, M.A., D.Sc., F.R.S., PROFESSOR OF ELECTRICAL ENGINEERING IN UNIVERSITY COLLEGE, LONDON.

The importance of possessing a secondary standard of light which shall be at once portable, convenient, and constant is generally acknowledged, and the choice lies between some form of flame standard and some form of incandescent standard. For the last eight years the author has employed as a secondary standard of light a type of large-bulb carbon-filament electric incandescent lamp, which was first devised by him in 1895 in connection with photometric work carried on in the Pender Electrical Laboratory of University College. These lamps were made by the Edison and Swan Electric Light Company, and a large number of them have been issued to the public under the name of the Fleming-Ediswan photometric lamp, together with a certificate of the author as to the photometric value. The principle underlying the construction of these lamps is as follows: It is well known that some types of carbon-filament glow lamp, when worked at constant voltage, slightly increase in candle-power for the first 50 hours or so of their life. After that time a stationary period is reached, and then a progressive drop in candle-power takes place. The initial rise in candle-power is due to a gradual consolidation in the filament with use, which reduces its resistance, and the subsequent decay in candle-power is chiefly due to the deposit of carbon upon the bulb.

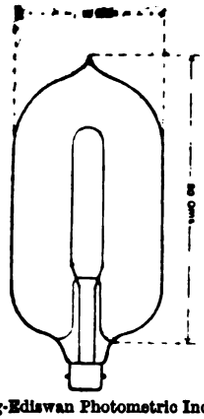

FIG. 1.—The Fleming-Ediswan Photometric Incandescent Lamp.

The surface of an ordinary incandescent lamp, 16 c.p., is approximately equal to that of a sphere 3cm. in radius, and may be taken, roughly, as 120 square centimetres. Accordingly, an ordinary small-bulb incandescent lamp is not very suitable as a standard lamp. The writer found, however, that by enclosing the filament in a bulb of much greater diameter, say in a cylindrical bulb 12cm. in diameter and 20cm. in length, giving a total bulb surface of nearly 800 to 1,000 square centimetres, the deposit of carbon upon the bulb was greatly diminished: first, because the glass is further removed from the filament, and, therefore, the chances of a carbon molecule getting on to the glass are reduced; and, secondly, because the carbon that is deposited is spread over such a much larger area of glass that its effect in interfering with the passage of light is greatly diminished. Again, it was found that by subjecting the carbon filament to a certain process of ageing in another bulb before transferring it to the large bulb, the rise in the resistance of the filament was, so to speak, anticipated. Accordingly, lamps were made to the following specification: Well-selected carbon filaments of the single-loop type of 10 c.p. or 16 c.p. were aged and adjusted to an efficiency of 3·5 watts a candle. These filaments were then transferred to large cylindrical bulbs of very clear glass and finished in the usual manner (see Fig. 1).

Such a large-bulb lamp may be called a photometric lamp. A mark is placed on the glass or on the collar of the lamp in such a position that when the lamp is mounted in the photometer with this mark facing the photometer disc, the axis of the lamp being vertical, the plane containing the horseshoe filament is perpendicular to the line joining the lamp with the photometer disc. These lamps are intended to be used in the following manner by a process of photometric "double weighing." Each standard lamp is marked with the voltage at which it will give a certain candle-power in the above-mentioned direction and position. A lamp is then used, as follows: Assuming it to be marked, say, 16 c.p. at 98 volts, the lamp is placed in the photometric gallery at a distance from the photometer disc of 4ft.—viz., the square root of 16—and by means of a potentiometer and variable resistance, the electric pressure on the terminals of the lamp is adjusted to be 98 volts. Under these circumstances the illumination on the photometer disc is *one candle-foot*. This is balanced by placing on the other side of the photometer disc another incandescent lamp worked at about the same watts per candle, the distance of this last lamp (called the comparison lamp) being adjusted until a photometric balance is obtained. The standard lamp is then removed from the photometer, and its place is taken by any lamp the candle-power of which it is desired to ascertain at a certain voltage. The voltage having been adjusted, this last lamp is then moved to or from the photometer disc until it photometrically balances the comparison lamp. Let us imagine that it balances the comparison lamp at a distance of 50in. The candle-power of this last lamp is then equal to 17·36 candles, being to the standard lamp in the ratio of the square of 50 to the square of 48. Such an operation has been called by the author a photometric double weighing, because it resembles the process by which the exact weight of an object can be ascertained by means of good weights with an imperfect balance. By following the above method no want of symmetry in the photometer vitiates the process of measurement, neither are we concerned with the exact value of the comparison lamp as long as it remains constant during the experiment. All that we are concerned with is the exact value of the standard lamp used for setting the comparison lamp, and with the ratio of the distance of the standard lamp from the photometer disc to that of the measured lamp. Hence, if the distances are correctly measured, we have the exact ratio between the candle-power of the standard lamp and that of the lamp being measured.

It has been found by large experience that this process is more accurate than the usual plan of placing the photometer between the two lamps and moving the photometer to and fro until the balance is obtained. In this last method we are liable to error in consequence of any want of symmetry in the photometer itself, and also by reason of the fact that the continnal moving of the photometer varies the value of the absolute illumination on the photometer disc. It has been found that even when using the best Lummer-Brodhun photometers there is a certain asymmetry in the instrument or the disc. If a photometric balance is obtained between two lamps, one on each side of the photometer, then on reversing the disc the balance is no longer obtained, but the photometer has to be moved to a further position. This difference is not apparent when the photometer is simply turned over, prisms and discs moving together, but differences amounting to 5 per cent. in the value of the readings of the candle-power of a lamp have been found in some instances when the disc alone is reversed.

These large-bulb lamps are not intended to be used as working standards and kept incandescent for any length of time, but merely as secondary standards for a few minutes to adjust the distance of the comparison lamp and from the photometer disc. In this manner it may be used many thousands of times without being in a state of illumination altogether for more than a few hours. By employing a number of these lamps and checking them one against the other, and never allowing the voltage on the lamp to exceed the marked volts, a means is provided of determining and preserving a standard of light with very considerable accuracy.

In connection with the construction of these large-bulb lamps, the following points are important. The filament should preferably be in the form of a single loop or horseshoe, and should be mounted in the large cylindrical bulb with great care so that the plane of the loop lies in the axial line of the lamp, filaments being selected with the two

* Paper read before the British Association at Cambridge.

Digitized by Google

sides of the loop in the same plane and not distorted. In some cases it is desirable to anchor the filament by a loose loop of platinum wire, sealed into the bulb, but such loop of wire should not touch the filament or constrain it when the lamp is at rest or in use. Owing to the fact that the 16-c.p. 100-volt filament is about 9in. in length, it is desirable, if possible, to employ a 10-c.p. 60-volt large-bulb photometric lamp as a standard. The 16-c.p. 100-volt lamp of this type is much used, and the 16-c.p. 200-volt lamp has been made, but is not recommended. It is not desirable to employ two filaments in parallel, as they may then be at different temperatures, but they can be placed in series, one loop within the other, and both lying in the same plane. In setting the lamp in the photometer, great care must be exercised to adjust the lamp axis perfectly vertical, and a plumb line should be employed to mark the position of the mean line of the filament as read on the scale of the photometer bench.

In the use of these lamps the following precautions should be taken: (1) the lamp should never be raised above the voltage marked upon it by the manufacturer; (2) in the next place, great care should be taken that good contact is made between the socket and the sole-plate on the lamp. It is better, therefore, to solder a pair of wires to each sole-plate of the lamp collar, one pair being employed as the leads for the current to the lamp, and the other pair as potentiometer or voltmeter wires to ascertain the exact potential difference between the sole-plates of the lamp. This adjustment of potential is best effected by means of a variable rheostat and a potentiometer. In the certificate issued with each of the Fleming-Ediswan photometric lamps, a statement is made of the exact voltage and current at which the lamp gives a certain candle-power at a certain temperature If used with the above precautions, experience accumulated during the past eight years has shown that these lamps are capable of preserving an exceedingly constant candle-power, and that as standards of light they are more portable and require none of the corrections necessary in the case of flame standards.

The great objection which may be urged against the use of all flame standards is the degree to which their candle-power is affected by moisture in the air and changes in barometric pressure. It has been shown by researches made at the Reichsanstalt on the Hefner lamp that the light emitted decreases about 0·5 per cent. with every additional litre of water vapour present in the atmosphere above a certain normal value. Taking the average variations of moisture in the air from month to month, we find that this implies a variation of about 4 per cent. in the light emitted in the Hefner lamp between the wet and dry seasons of the year; this variation greatly exceeds the limits of possible error in photometric observations. With very little care photometric comparisons can be made within 1 per cent., hence comparisons with a flame standard are not sufficiently definite unless the value of the flame standard has been corrected for moisture and barometric pressure. The authorities of the Berlin Reichsanstalt take the standard state of the atmosphere with regard to moisture to be that in which it contains 8·8 litres of water vapour per cubic metre of dry air. The atmosphere of Berlin, however, is distinctly drier than that of London, and the author has been informed by Dr. Glazebrook, F.R.S., director of the National Physical Laboratory of England, that he considers for Great Britain it will be better to take as a standard state 10 litres of water vapour per cubic metre of dry air as more nearly representing the average state of the British atmosphere.

Dr. Glazebrook has made a prolonged study of the Harcourt pentane 10-candle lamp in regard to variation of candle-power of the latter with atmospheric moisture and pressure, the results of which he will no doubt make known in due time. Meanwhile he has privately communicated to the writer information which shows that the correction of the candle-power in the pentane lamp, due to moisture in the air—or, rather, deviations from the standard state of moisture—is at least as great as that of the Hefner lamp. There seems reason to believe that this correction would be about the same for all flame standards. Dr. Glazebrook has been so kind as to communicate to the writer a formula for the correction of the pentane lamp for variation in illuminating power due to atmospheric moisture and pressure which he has obtained, but it must be considered as merely privately and unofficially furnished, and, therefore, subject to any future correction by him * Taking the Harcourt 10-candle pentane lamp to emit a light of 10 c.p. when the barometric pressure is 760mm. and the atmospheric moisture 10 litres per cubic metre, then the candle-power corresponding to a barometric pressure of b millimetres and a hygrometric state of e litres of water vapour per cubic metre, he finds that candle-power can be expressed as follows: candle-power of the Harcourt pentane lamp $= 10 + 0{\cdot}066\,(10 - e) - 0{\cdot}008\,(760 - b)$. The water vapour present may often reach 15 or 16 litres per cubic metre. This variation alone will decrease the candle-power by 3 per cent. or rather more. Hence, if the correction is not applied, and the pentane lamp is then used directly to standardise an incandescent lamp, and assumed to be 10 c.p., the candle-power of the electric lamp may be marked as much as 3 per cent. too high. In other words, an error of nearly 0·5 c.p. may be made in marking a 16-c.p lamp. This source of error only presents itself in comparing a flame standard with an incandescent lamp. When two flame standards such as coal gas and pentane are being compared, the atmospheric moisture affects both flames about equally.

The writer has recently had careful tests made to ascertain if these large-bulb incandescent lamps gave the same candle-power at the same voltage and current, irrespective of variations in the temperature of the surrounding atmosphere. With this object an experiment was made by Mr. G. B. Dyke in the photometric gallery of the Pender Electric Laboratory, at the suggestion of the author. A large iron box was provided, having an oval hole in front, about the size of one of the large-bulb lamps. A lamp of this description was mounted on a socket and suspended in this box with its axis vertical. At the bottom of the box were placed some coils of iron wire which could be heated by an electric current. In this manner the temperature of the air in the box was gradually raised and the lamp was surrounded by an atmosphere of warm air. The temperature of this air was taken by four thermometers placed in the box. The readings of these thermometers were taken together with the candle-power of the lamp, and the values ou nd to be as follows:

Atmospheric temperature in centigrade degrees.								Candle-power of large-bulb lamp.
(I.)		(II.)		(III.)		(IV.)	Mean	
23°·6	...	24°·4	...	22°·8	...	22°·8	23°·4	13·84
27°·4	...	27°·7	...	28°·0	...	26°·4	27°·4	13·81
42°·0	...	44°·4	...	46°·9	...	37°·5	42°·4	13·81
67°·2	...	69°·4	...	77°·2	...	53°·3	66°·8	13·77

Hence it is clear that there is practically no change in the candle-power of the lamp with change of temperature of the surrounding atmosphere.

These lamps, therefore, present the following valuable features when employed as secondary standards of light: (1) The candle-power does not vary with the atmospheric moisture, barometric pressure, or atmospheric temperature. (2) If the lamp is properly prepared and used as described, the candle-power given by it depends on nothing but the current passing through the filament, and this last can be measured to within 0·1 per cent. or less by means of a potentiometer, and the candle-power, therefore, known to within 1 per cent. The experience so far gained shows that if a number, say six, of these standard photometric lamps are kept and compared with one another at intervals, the observer has always the means at his disposal of determining the candle-power of an incandescent lamp within 1 per cent. (3) Great portability as a standard. The lamp is very portable, and there is no difficulty in sending these lamps suitably packed to the other side of the world. Anyone with secondary cells as a source of current and a potentiometer as a measuring instrument has the means of setting up a standard of light at least as accurate and constant as a good flame standard. These lamps, in fact, afford the best means of determining the variation of flame standards with barometric pressure and atmospheric moisture, and

* An account of these researches was given in a paper read before Section G of the British Association immediately after the present paper by Mr. C. C. Paterson, who conducted the experiments at the National Physical Laboratory on this subject.

Digitized by Google

photometric comparisons between a large-bulb lamp as devised by the writer and a flame standard is, in fact, a checking of the latter by the former and not the reverse.

In equipping an electrical laboratory with the means of preserving a standard of light, the author recommends the following procedure as the result of eight years' experience of it. A stock, say, of 12 of the large-bulb photometric lamps is provided. Those of the writer's pattern issued by the Edison and Swan United Electric Light Company are each sent out in a stout millboard box. These lamps should all have their candle-power carefully determined at a marked voltage, so chosen that the efficiency is about four watts per candle. The current at this voltage should be measured. This candle-power current and voltage should be marked on the box. If this calibration is made against a flame standard, then the greatest care should be taken to correct the value of the flame standard for atmospheric moisture and pressure. The candle-power ratios of these lamps should be taken, and six of them should be preserved as ultimate standards of reference for the adjustment of the other six. These last may be used for setting the comparison lamp in the photometer, and they should be compared at intervals with the first six lamps which are reserved as prime standards of reference. If the six working lamps are used turn-and-turn about, and inter-compared with the reference standards, they may be used thousands of times without being actually burning for more than a few hours, and the tradition as to the unit of light or illumination can be transmitted without risk of change.

As an instance of the utility of these lamps in the comparison of flame standards, it may be mentioned that the author recently sent three of these large-bulb standard

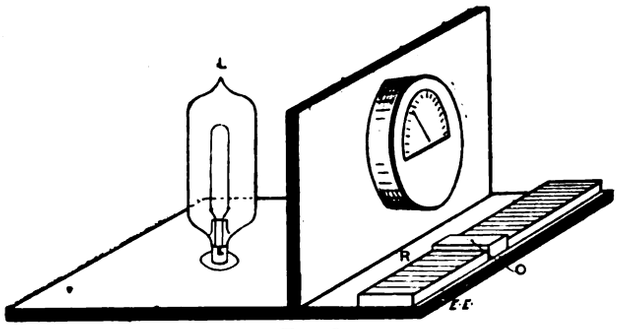

FIG. 2.

lamps to Berlin by his assistant, Mr. W. C. Clinton, and they were photometrically measured in the Physikalisch Technische Reichsanstalt at Charlottenburg. The same lamps were subsequently taken to the National Physical Laboratory, Bushy House, Teddington, and measured independently. In Berlin the standard of comparison was a Hefner lamp, and at Bushy House it was a Harcourt 10-c.p. pentane lamp. The ratios of the certified readings gives us the value of the Hefner unit in mean British candles, and it is close to the value usually assumed. These three lamps are called Pender IV., Pender VI., and Pender X. respectively. The results are tabulated below:

Lamp mark.	Value of the illuminating power in Hefner units assigned at the Reichsanstalt. H.U.	Value of the illuminating power in British candles assigned at the Nat. Phys. Lab. C.P.	Value of the Hefner unit in British candles.
Pender IV.	15·1	13·41	0·888
Pender VI.	12 6	11·12	0 883
Pender X.	15·9	14·07	0·885

The mean value of the ratio is 0·885. The lamps were all measured at 96 volts, and the current values obtained at the Reichsanstalt agreed with those obtained at Bushy House within 1 part in 1,000. Hence we may take it that the above fraction (0 885) represents very nearly the ratio between the Hefner unit as employed at Berlin and the mean British candle as employed in London as a standard of illumination.

In connection with these large-bulb lamps, the author has arranged a simple apparatus, consisting of a large-bulb lamp, a rheostat, and an ammeter, the range of which comprises merely the ordinary lamp currents. The ammeter is, however, not graduated to read amperes, but graduated to read candle-power, so that if the rheostat is adjusted to make the ammeter needle point to any part of the scale, that scale reading would at once, without further calculation, give the candle-power of the lamp in the normal direction. Although this apparatus is not accurate enough for laboratory purposes, yet for workshop or generating station purposes it is a convenient arrangement for obtaining a fairly accurate standard of light without the complications involved with the use of the potentiometer. The arrangement of the apparatus is shown in Fig. 2.

In conclusion, the author has to record his thanks to Mr. W. C. Clinton, B.Sc., for much laborious and careful work during many years in making numerous photometric comparisons, but the experience so gained has every year tended to confirm the opinion that these large-bulb incandescents, when used as described, form a most convenient and constant standard of light.

THE RELUCTANCE OF THE AIR-GAP IN THE INDUCTION MOTOR.

BY N. PENSABENE, A.I.M. (BELGIUM).

In a preceding article* we have studied the reluctance of the air-gap in induction motors having open slots in the stator, and totally enclosed slots in the rotor. In that which follows we propose to consider the case of semi-enclosed slots in stator and closed slots in rotor, and the other case in which both, stator and rotor, have semi-enclosed slots.

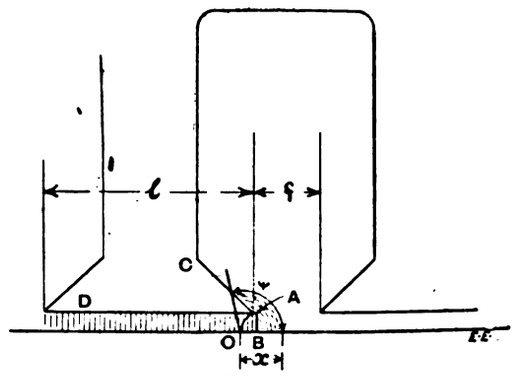

FIG 1.

I. For the sake of simplicity let us suppose that the shape of the stator slots is as shown in Fig. 1, in which the portion A C has been represented by a straight line instead of a curve, as is generally the case in practice. Starting from the same hypothesis as for the case already studied—that is, supposing the lines of the magnetic field consisting of circles with their centres in O, so that O B = d—and using the same notation as before, we have for the permeability of one tooth

$$P = \frac{L\,l}{d} + 2\,L \int_{d}^{d+\frac{f}{2}} \frac{d\,x}{x\,\psi}.$$

The angle ψ, shown in Fig. 1, is a function of x. With sufficient accuracy for the purpose, we may say

$$x\,\psi = (\pi - \alpha)\,x - C,$$

where $\alpha \times \overline{C\,A\,D}$, $C = \sin\alpha\,(1 + \cot\alpha) = \sqrt{1 + \sin 2\,\alpha}$. So we get

$$P = \frac{L\,l}{d} + \frac{2\,L}{\pi - \alpha} \log\left[\frac{\pi - \alpha}{2\,(\pi - \alpha - C)}\,\frac{f}{d} + 1\right]. \quad (1)$$

We see, then, that the permeability, P, varies with the angle α. For $\alpha = \frac{\pi}{2}$ (open slots), $C = 1$, and

$$P = \frac{L\,l}{d} + \frac{4}{\pi}\,L \log\left[1{\cdot}38\,\frac{f}{d} + 1\right],$$

which is the formula already found for open slots.

Formula (1) is not suitable for practical applications, being too complicated. We can simplify it, if we notice

* The *Electrical Engineer*, June 17, p. 922.

Digitized by Google

that in practice the angle α does not vary much from the average value of 35deg. In this case

$$C = \sqrt{1 + \cdot 94} = 1 \cdot 4,$$

and

$$P = \frac{L\,l}{d} + \cdot 8\,L \log \left[1 \cdot 12 \frac{f}{d} + 1 \right].$$

From this formula we get as before:

$$A_a = P\,d\,S = \times L \left[l + \cdot 8 \log (1 \cdot 12 \frac{f}{d} + 1)\,d \right],$$

and if

$$\epsilon = \cdot 8 \log \left(1 \cdot 12 \frac{f}{d} + 1 \right),$$

we have

$$A_a = L\,S\,(l + \epsilon\,d) \quad . \quad . \quad . \quad . \quad (2)$$

In Fig. 2 we have plotted the curve 2 which gives the different values of ϵ according to the ratio $\frac{f}{d}$. Curve 1 is the curve already found for open slots.

II. We now come to the most general case, where the slots are semi-enclosed in both stator and rotor. The problem which we have seen is a simple one for the two preceding cases here becomes complicated because the reluctance is not any more constant, but varies with the relative position of the stator and rotor teeth. We prefer not to enter into long and elaborate calculations which lead to a formula of no practical value. For the accuracy needed in practice it seems quite satisfactory to calculate A_a with formula (2), using the curve 2 (in Fig. 2) and denoting with S, l, f, the average values of these elements corresponding to the stator and rotor.

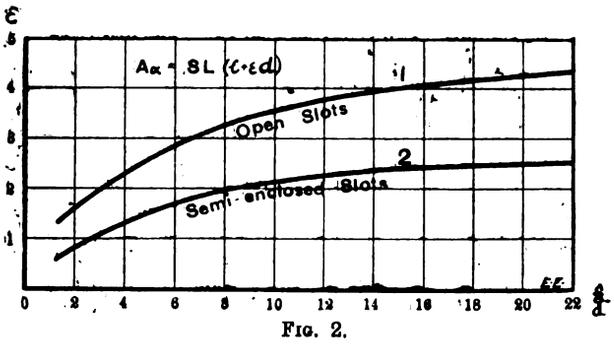

FIG. 2.

In conclusion, then, for all the cases formula (2) is to be used; for open slots in stator and enclosed slots in rotor, ϵ is given by the curve 1 in Fig. 2; for semi-enclosed slots, ϵ is given by curve 2. The following experimental corroboration of above refers to the common case of semi-enclosed slots in stator and rotor. The way of proving the accuracy of the formula found is the same as the one already used for open slots. The correction for the iron reluctance has been done by increasing the air-gap length by 10 or 15 per cent., according to the saturation of the iron. The formula is

$$i' = \cdot 44 \frac{e\,p\,d_1}{n^2 \cdot \sim A_a} 10^8.$$

The following data refer to 10-b.h p. and 20-b.h.p. motors made by the General Electric Company. The tests on these motors were carried out at the works of this firm by Mr. R. W. Weekes and Dr. W. E. Sumpner, with a new method suggested by the latter.* In designing these motors for the above firm, the writer has estimated the air-gap reluctance with the exposed method; it will be seen that the errors incurred are about of the same order as the errors in commercial testing machinery.

1. The data for the 10-b.h.p are (average values for stator and rotor elements): S = 10·5, f = ·35, l = 1·13, d = ·065, n_1 = 216, d_1 = ·075†, p = 6, L = 11·8, and the test was made with e = 134 V, $\sim$ = 40·6.

We have then $\epsilon = 1 \cdot 6$,

and $A_a = 10 \cdot 5 \times 11 \cdot 8\ (1 \cdot 13 + 1 \cdot 6 \times \cdot 065) = 151$,

and $i' = \frac{\cdot 44 \times 134 \times 6 \times \cdot 075}{216^2 \times 40 \cdot 6 \times 151} 10^8 = 9 \cdot 5$ A.

* See the *Electrical Engineer*, June 17, "A Hopkinson Test for Multiphase Induction Motors," by R. W. Weekes, M.I.E.E.

† The maximum inductions are: for the narrowest points of stator teeth 18,000 lines per square centimetre and for the core 7,000 lines per square centimetre.

It is easy to see that, the two 10-b.h.p. motors being identical, they have the same admittance at open secondary, then the currents given in the test made by Mr. Weekes in Table I., columns 3 and 4, reading No. 11, are double the light current of each motor, so

$$i' = \frac{20\,6 + 21}{4} = 10\,5.$$

2. In the same valuable article published by Mr. Weekes, we find another test of two motors, 25 b.h.p. and 30 b.h.p., belted together.

Taking in consideration the 25-b.h.p., we have S = 12, f = ·35, l = 1·42, d = ·075, d_1 = ·085, n_1 = 90, L = 21·6, p = 6, e = 138 V, $\sim$ = 41. Then

$$\epsilon = 1\,5,$$

and $A_a = 12 \times 21\,6\ \{1 \cdot 42 + 1 \cdot 5 \times \cdot 075\} = 400$,

and $i' = \frac{\cdot 44 \times 138 \times 6 \times \cdot 085}{90^2 \times 41 \times 400} = 23 \cdot 5$ A.

From columns 6 and 7 of Table III., reading No. 13, we have i' = 24 5 A.

3. The following examples have been taken from the motors described by Mr. Hobart,* who gives in his article the actual observed light currents. The saturation being low, we take $d_1 = 1 \cdot 1\ d$.

Motor A.—S = 16 5, f = ·3, l = 1·1, L = 33, p = 12, d = 15, d_1 = ·165, n_1 = 180, e = 290 V, $\sim$ = 50.

We have $\epsilon = \cdot 90$,

and $A_a = 33 \times 16 \cdot 5\ (1 \cdot 1 + \cdot 9 \times \cdot 15) = 670$,

and $i' = \frac{\cdot 44 \times 290 \times 12 \times \cdot 165}{180^2 \times 50 \times 670} 10^8 = 23 \cdot 5$ A.

The test gives i' = 23 A.

4.—Motor C.—S = 19 5; f = ·25; L = 75; l = 1·45; p = 30; d = ·175; d_1 = ·193; e = 2,900 V; $\sim$ = 25; n_1 = 1,200.

We get $\epsilon = \cdot 75$,

and $A_a = 75 \times 19 \cdot 5\ (1 \cdot 45 \times \cdot 75 \times \cdot 175) = 2{,}300$,

$$i' = \frac{\cdot 44 \times 2{,}900 \times 30 \times \cdot 193}{1{,}200^2 \times 25 \times 2{,}300} = 9 \text{ A.}$$

The test gives 9·3 A.

LONG-DISTANCE SWITCHES.†

(*Concluded from page 275.*)

The diagram of connections of a long-distance switch introduced by the Siemens-Schuckert-Werk is shown in Fig. 10. If the switch u is put on to contact 1, coil a becomes excited, pulls its armature up, and, by means of an ingenious handle mechanism, closes the switch b. As soon as the circuit is completed the current ceases in a and the armature returns to its original position, but b remains closed. In order to switch off, the switch u is moved on to 2, a receives current again, pulls its armature up, and this, by means of the handle mechanism, opens the switch b again. At the same time the exciting current in a is stopped. All the above described switches are suitable for low-tension circuits.

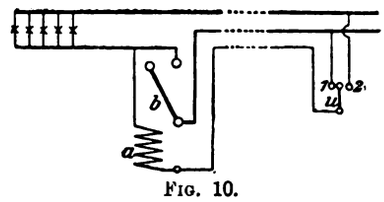

FIG. 10.

The introduction of high tensions has led to the introduction of arrangements by which the high-tension and low-tension circuits on central-station switchboards can be kept entirely separate. The operation of the high-tension switches is often carried out by means of more or less complicated auxiliary mechanism. On this account it has

* See "Traction and Transmission," "Electric Motors," May, 1904, pp. 39 and 40.

† Translation of an article in *Elektrotechnische Zeitschrift* for July 28, 1904, by F. Lindenstruth and O. Forster.

Digitized by Google

become common in America to work the switches electrically, either directly or with the aid of compressed air. In this way the switchboard, besides the measuring instruments, only carries a number of small low-tension switches or bell pushes, through which the high-tension switches are actuated. Indicators or signals at the same time show the connections made. The current for operating the high-tension switches may either be taken from the exciting circuit or from any other available low-tension supply.

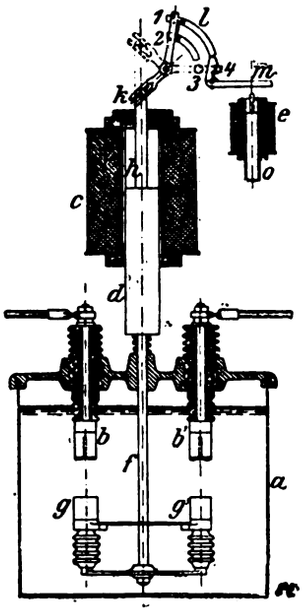

FIG. 11.

The above arrangements can, of course, also be employed for the switching in and out of distant transformers in order to reduce the light-load losses, and several devices for this purpose were described in the *Elektrotechnische Zeitschrift*, 1901, No. 17, and 1902, Nos. 24 and 25.

Modern high-tension switches are almost invariably of the oil-break type, and an automatic switch of this sort is shown in Fig. 11. The apparatus consists of the oil-holder, *a*, with the terminals, *b*, fixed to the cover by porcelain insulators. The switch on coil *c* is fixed above the oil-holder. The core *d* carries the insulated contact pieces, *g g'*, by means of the rod, *f*; *d* is continued upwards by means of a brass rod, *h*, a projection on which works in the fork of the arm, *k*. The latter carries a brush, *l*, which makes contact either with 1 and 2 or with 3 and 4, according to the position occupied by the handle. When coil *c*

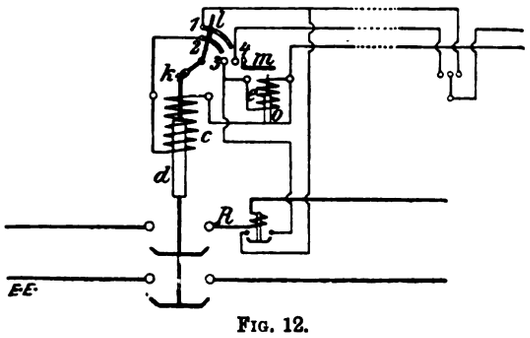

FIG. 12.

is excited *d* is drawn up, and makes contact between *g g'* and *b b'*. At the same time the handle, *k*, reaches the dotted position and is held there by the locking trigger, *m*. Before this extreme position is reached the brush, *l*, will have left contacts 1 and 2 and will connect 3 and 4. The current in the switching-on coil then ceases, whilst the switching-off coil, *e*, can have current sent through it when required. If such a current is sent the core *o* is pulled right up, releases the trigger, *m*, and the core *d* falls to its original position and open the circuit. Apparatus of this sort is as readily applicable to alternating as to direct currents. It is even unnecessary to employ laminated iron for the former, as the coils are only excited for very short intervals. Fig. 12 shows the connections of such a high-tension long-distance switch. In this case a relay, R, has been added, which sends current round the switching-out coil as soon as the main current exceeds a given value, and so makes the arrangement into a simple maximum cut-out.

Fig. 13 is the diagram of connections for two transformer stations feeding a single low-tension network at two different points. In order to reduce the no-load losses to a minimum at times of light load, one of the transformers (I.) is arranged to be cut out, station B being able to deal with the average load alone without objectionable voltage drop. At a certain load the relay *f* in station II. closes the circuit of relay *c*, which, after a certain (adjustable) lapse of time, closes the circuit of the switching-in coil, *a*,

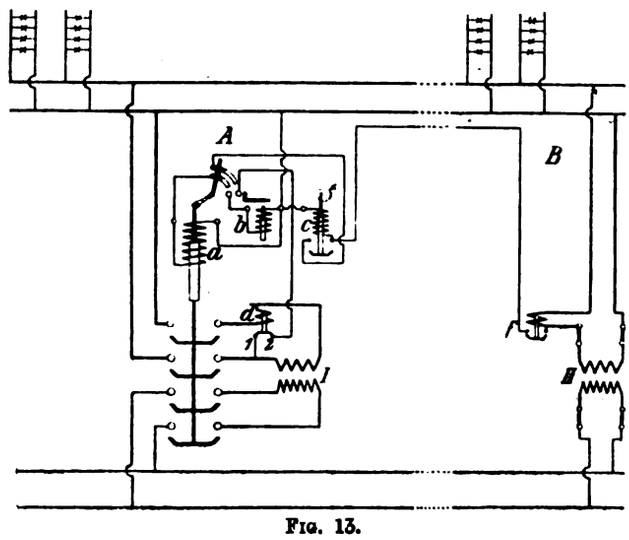

FIG. 13.

in station I. At the same time a relay, *d*, on the low-tension side of station I. opens contacts 1 and 2 when a certain current is reached. When the load on the network falls again, *d* connects contacts 1 and 2, thus making the circuit through *b*, which throws transformer I. out of circuit again. By the use of a maximum relay in station A transformer I. can be protected against overload in the way shown in Fig. 12. The time relay, C, is not absolutely necessary, though without it instantaneous short-circuits in the network would cause transformer I. to be immediately put into circuit.

WALLASEY TRAMWAYS.

The following is an abstract of the revenue account for the year ended March 31, 1904, taken from the annual report of Mr. R. R. Greene, general manager, to the chairman and members of the Tramways Committee.

REVENUE ACCOUNT.

Dr. Expenditure.	£	s.	d.
Maintenance of cars	2,105	3	1

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notices of Meetings, Issues of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had by Order from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	— 6s. 6d.	— 13s. 0d.
Other Places	5s. 6d.	— 10s. 6d.	— 21s. 0d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

Bound Volumes of "The Electrical Engineer," *containing half-year's copies, bound in Dark-Blue Cloth, Gold Lettered, price 8s. 6d. New Volume, January to June, 1904, now ready.*

THE CAMBRIDGE MEETING.

The British Association for the Advancement of Science have this year had a most successful meeting in the university town of Cambridge. The advantages of holding the annual gathering of the association in a town devoted as Cambridge is to the dissemination of knowledge are many. In the first place, it is the home of numerous scientific men who are the better able to put before the meetings their most recent researches. In the second place, the facilities in the way of lecture theatres are good, and every modern appliance has been placed at the command of the readers of papers. Thirdly (but first, as the wicked detractors of the British Association would say), the opportunities for sightseeing, garden parties, and social functions generally are exceptional. This year the association was honoured by having the Prime Minister as president. The Right Hon. A. J. Balfour, M.P., has every qualification for this position, and filled it admirably. The presidential address showed the depth of his scientific thought, and his regular attendance at the meetings of the sections was evidence of his keen desire for further information. We are afraid that this afforded little refreshment to the Prime Minister after his arduous work of the past session. It is true, in a sense, that a change of employment is a rest, but the atmosphere of the room in which Section A was held was even worse than that in the House of Commons after an all-night sitting. It was a good reply to those who hold that the British Association is merely a scientific picnic. The drawing office of the engineering laboratory was used by this section, and on Tuesday last was crowded throughout the whole of the morning to hear a number of communications on radioactivity and ionisation. These subjects have been the successful hunting ground of the Cambridge school of scientists under the able leadership of Prof. J. J. Thomson. When, therefore, this expert, Lord Kelvin, Prof. Schuster, and other workers on the subject were communicating their original results an exceptionally large audience was attracted, and but for the state of the air in the room one could truly say they were listened to with breathless interest. Prof. J. J. Thomson's opening speech in the discussion on the radioactivity of ordinary matter was a masterly exposition of the researches carried out at Cambridge under his direction. He showed the extreme difficulty of distinguishing between the primary radioactivity of a substance and the radioactivity induced in it by the influence of other radioactive substances, such as radium and thorium. There was also the difficulty of deciding whether a substance was radioactive because of its impurities containing small quantities of these radioactive materials. Prof. Thomson described how by enclosing a small charged plate in a metal box, and screening this box from outside rays, his students had secured definite and consistent figures as to the ionisation of the enclosed air. With different metals for the sides of the box, consistent varying results were obtained, even although the same metal used in two experiments came from widely different parts of the earth. Experiments in altering the size in the containing boxes enabled further analysis as to the source of the waves to be made, and the conclusion arrived at was that all ordinary matter was more or less radioactive. Definite figures were given, and although the conclusions were disputed by one or two other scientists, they were generally accepted. The compliment paid by Sir Oliver Lodge to the Cambridge experimenters is worthy of repetition. He said that there were such a large number of experimenters now at work on radioactivity, and such a legion of experiments published, that one

Digitized by Google

could not begin to remember them all. It was only at Cambridge that theory and fact were advancing together, and the theory enabled the facts to be remembered. Other sections of the association were also well attended, and the papers brought before Section G were of a higher order than usual. The section, however, is still as badly organised as ever, and the engineering committee would do well to take a lesson from Section H, which is devoted to anthropology. In this section eight or nine communications were frequently got through in a morning, due to the fact that the time allowed for each was fixed beforehand. In the engineering section the first two or three papers took the whole of the time each day, and then the members adjourned to lunch, leaving the other authors to read their communications to the president and secretary.

FORTHCOMING EVENTS.

SATURDAY, SEPT. 3.

Association of Municipal and County Engineers.—District meeting at Birmingham.

APPOINTMENTS VACANT.

Mechanical Engineer. Messrs. Deacon's, Leadenhall-street, E.C. See advertisement.

Station Superintendent, Ilford electricity supply works. Salary £150 per annum. See advertisement.

Electrical Engineer. Mr. Frank Broadbent, consulting engineer, 4, Queen-street-place, E.C. See advertisement.

Draughtsman, Croydon. Salary £2. 5s. per week. Applications to Mr. Alex. C. Cramb, borough electrical engineer, Electricity Works, Croydon, by Sept. 5. See advertisement.

Switchboard Attendant, Kirkcaldy electricity works. Wages 25s. per week. Applications by 27th inst.

Resident Electrical Engineer, Willesden Urban District Council. Salary £250 per annum. Applications by Sept. 17.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

TELEPHONY AT GLASGOW.

SIR,—I see that it is necessary to proceed patiently with this discussion, and to settle one point at a time. In his paragraph last week "W. O. T." calmly ignores the fact, clearly shown in my letter above, that the 1897 estimate described a totally different system from "the then existing system," and he assumes that it described a similar equipment. Mr. Bennett, in his communication, contributes several fresh errors and contradictions.

I must again state the point we are discussing. It is that the 1897 estimate was made "for the special purpose of showing what *the then existing telephone system* in Glasgow *ought to have cost* the National Telephone Company." "W. O. T." has said that he believes this to be entirely true, and that he has based all that he has written on it.

Now, sir, the first point of all, and one that I regretfully note "W. O. T." has extreme difficulty in grasping, is that an estimate to show what an existing system ought to have cost would describe a system similar to the existing system. The existing system of the National Telephone Company in Glasgow in 1897 was an overhead single-wire system. That is clearly shown in the report of the enquiry. If the estimate has been drawn up for the purpose of showing *what the existing system ought to have cost*, it would have described a similar system—that is, an overhead single-wire system.

I think I made it clear to any ordinary reader of my last letter that the estimate did *not* describe a similar system. It described a totally different system, and Mr. Bennett, in his evidence describing his estimate, drew as many distinctions as possible, in respect to the general design of the system, the quantity and quality of materials to be used, and the number of junction lines and switch-rooms to be provided, between his proposed system and the existing system. Therefore, the equipment described in the estimate and by the estimator was not a similar equipment to the existing equipment, but a totally dissimilar one.

"W. O. T." says he wants the truth. Why, then, should he persist in stating what is not the truth? In his paragraph appended to my last letter, notwithstanding that it is clearly shown in that letter that the 1897 estimate described a totally different system from the 1897 existing system, he persists in referring to the estimate as if it described a system similar to the 1897 existing system. He says, Mr. Bennett asked himself what would be the cost to replace the company's equipment by *a similar equipment*. He says, Mr. Bennett and the town clerk of Glasgow got tenders for *a similar equipment*. And again, below, he refers to the Glasgow committee being satisfied with the equipment *similar to that which existed*.

This is not argument, it is a weary reiteration of error. There is no similarity between a metallic circuit underground system and an overhead single-wire system. The estimate described a metallic circuit underground system, the existing system was a single-wire overhead system; therefore the estimate did not describe, the town clerk did not get tenders for, and the Glasgow committee did not consider a *similar equipment* to the company's equipment of 1897. Until "W. O. T." can realise this point clearly, we are arguing at cross purposes.

Regarding Mr. Bennett's communication, the value of it is somewhat diminished by the fact that it was written as an editorial, to be published anonymously, and it is still further diminished by the fact that whereas Mr. Bennett assumes that he is answering my criticisms, he is really trying to answer his own contradictory statements.

Mr. Bennett seems to have been not wholly frank in his evidence before the 1898 Select Committee. He was asked if there were anything to modify his evidence at Glasgow, and he said "No." Why did he not tell the committee that the Glasgow estimate "was for the special purpose of showing what the then existing telephone system ought to have cost the National Telephone Company"? That would have entirely changed the bearing of his evidence.

Apparently, Mr. Bennett now wishes to imply that his evidence regarding the Glasgow estimate before the 1898 Select Committee was subject to the mental reservation that it referred only to the possibility of building in Glasgow a certain kind of system, of a certain size, serving in a certain way a certain fixed group of subscribers situated in certain fixed localities, for a certain capital sum. The committee certainly did not take Mr. Bennett in that way; their report plainly shows that they understood him to be instructing them in the cost of telephoning the Glasgow area.

I am aware that Mr. Bennett "hedged" on his Glasgow estimate under cross-examination, but that is nothing unusual. Mr. Salvesen, after the estimate had been criticised in detail, hedged still further, but he was only backing up his client, as is a lawyer's duty.

Mr. Bennett now makes the remarkable statement that the National Telephone Company asserted that they had spent on their 1897 Glasgow system "four or five times the amount which Mr. Bennett estimated was the proper expenditure for an exchange of that kind." Am I correct in interpreting this to mean that the National Telephone Company asserted that they had spent £400,000 or £500,000 on an exchange of 5,000 lines, and will Mr. Bennett kindly give his authority for that statement.—Yours, etc.,

HERBERT LAWS WEBB.

35, Old Queen-street, S.W., Aug 22, 1904.

SIR,—I have made up my mind to take no further notice of Mr. Webb's stupidities, but in view of "W. O. T.'s" remarks in your last issue, I think the annexed excerpt from the proceedings of the Local Government Board telephone enquiry in Hull last year, taken from the Hull *Daily News and Express*, will be of interest, as it shows that "W. O. T.'s" views coincide entirely with the Local Govern-

Digitized by Google

ment Board inspector's. Mr. Webb, in his evidence, had stated exactly what he has done in his letters to you about the original five-thousand line system at Glasgow, and he and Mr. Robb did their best to make capital out of it in favour of the National Telephone Company. Colonel Slacke, however—who I may say was unknown to all the parties—consulted the Glasgow Blue-book for himself, and then committed himself to the strong language reported as to Webb's and Robb's conduct. You will see that "W. O. T." and Colonel Slacke arrive at exactly the same opinion. This incident, being unfavourable to the National Telephone Company and its advocates, is not included in the so-called Blue-book of the Hull telephone enquiry recently published by one of your contemporaries.

It will perhaps be within your recollection that Sheriff Jameson, the commissioner of Glasgow, in his report referred to my original estimate in terms which proved that he understood it thoroughly, and never thought of construing it in the same way as Webb would have you believe that he does.

Mr. Webb has consequently both the Hull and Glasgow judges against him.—Yours, etc, A. R. BENNETT.

The telephone enquiry was continued at the town hall this morning before Colonel Slacke, the Local Government Board inspector. The town clerk (Mr. E. Laverack) again appeared for the Corporation, whose application was supported by Mr. Dixon, on behalf of the Hull and District Chamber of Trades, and Dr. Woodhouse, on behalf of a ratepayers' committee. Mr. Robb and Dr. T. C. Jackson opposed.

At the outset Mr. James Watson remarked that there were two points upon which he would like to have a clear understanding. Supposing there were not sufficient subscribers to the municipal telephonic system to meet the working expenses, etc., could they increase the rates in the future to meet any deficiency?

The Town Clerk: Certainly.

With respect to moneys that you have borrowed for a specific purpose—those moneys are only used for that specific purpose?

The Town Clerk: That is so.

The Inspector: If there be any deviation from the scheme put forward, it would have to be submitted to the Local Government Board.

MR. ROBB AND HIS ASSERTIONS.

Mr. Bennett then asked Mr. Robb if he was prepared to withdraw what he said yesterday about the Glasgow enquiry. Mr. Robb had made certain allegations, and he (Mr. Bennett) earnestly wished that they should be withdrawn.

The Inspector: I remember the incident quite well.

Mr. Rabb (emphatically): I am not prepared to withdraw. My view on the matter is the same now as it always was, and is in harmony with the views of everyone who attended that enquiry. Mr. Webb, who gave evidence at that enquiry, tells me that Mr. Bennett's system for 5,000 subscribers was, in the first instance, evidently put in as a working scheme. Well, it is true that in the course of the enquiry Mr. Bennett referred to it as a mere comparison, and that he did say, after he actually proceed to telephone the city, that he would provide for a larger scheme.

GLASGOW AND HULL.

My point is this, that Mr. Bennett is suggesting a similar system here. In the Glasgow system Mr. Bennett said he would provide for 5,000 subscribers only, because it compared with the 5,000 subscribers of the National Telephone Company there. But in Hull Mr. Bennett is providing less—he is providing for 2,000 subscribers, where the National Telephone Company have 3,000 subscribers. Wherefore, if Mr. Bennett proceeds on the same scheme as Glasgow——

The Inspector: That is not the point. Mr. Bennett merely put forward the system for 5,000 subscribers as a scheme.

Mr. Robb then proceeded to quote from the report of the Glasgow enquiry, and concluded with the words, "There, sir, I think that clearly proves my point."

"PERFECTLY UNJUSTIFIABLE."

The Inspector: To my mind it clearly proves that you have taken the wrong view (laughter). I don't think you ought to have expressed your opinion in the way you did yesterday with regard to Mr. Bennett. It has been the only incident in this enquiry that I might describe as being of a personal matter. I was in the hopes that this enquiry would have been conducted free of personal references. Under such a serious allegation I think Mr. Bennett is perfectly right in calling attention to the incident. I think that such a remark was perfectly unjustifiable, and I regret that this personal element has been introduced. I further think that the movers in this scheme appear to have been actuated only by their views as to what is best for the city, and, in that way, for the ratepayers, and I cannot believe it is in accordance with the views of those for whom you are acting that you should express yourself in the manner you did.

Mr. Robb: I put it forward not as a personal matter, but as an illustration.

The Inspector: Well, I will hear no more of the matter.

SIR,—I am just a little surprised at Mr. Bennett's vindication of himself. It is all right, of course, as far as it goes, but, as an outsider, though desirous of getting at the real facts, I should have thought his triumphant vindication would have been found in Mr. Andrew Jameson's report dated Nov. 29, 1897, issued 1898 (C 8,768); price, 2½d. Mr. Jameson heard all the evidence for and against, he being the gentleman instructed to hold the public enquiry. After referring to another estimate Mr. Jameson goes on to say:

"But a new estimate has now been prepared by Mr. Bennett, which is based upon the footing of there being the same number of subscribers as there are at present to the National Telephone Company, and which shows a capital expenditure of £97,833. 3s. 8d., and professes to show a satisfactory working of the system at a uniform charge of £5. 5s. per instrument all over the Glasgow district area. As will be seen from Mr. Bennett's cross-examination, the correctness of this estimate is questioned by the National Telephone Company; but the estimate itself is of very little use for practical purposes, because from what the counsel for the Corporation said in answer to the commissioner, it appears that Mr. Bennett's view, if he were to advise the Corporation, is that they should lay down a system sufficient to accommodate from 20,000 to 25,000 subscribers, as, indeed, Mr. Bennett himself says. This would, of course, cost a great deal more money—perhaps about four times as much as the estimate of £97,833. 3s. 8d.; but this view seems not to have occurred to the gentlemen who considered this matter on behalf of the Corporation, because Bailie Alexander, the convener of the Telephone Committee, only contemplates spending £100,000 to £120,000, while it is quite certain that a very much larger sum than that would be required to establish a system for 25,000 subscribers. And Treasurer Colquhoun has apparently not gone into the question as to how much every new 1,000 subscribers would cost, although he says they look forward to getting ultimately 40,000 to 50,000 subscribers in Glasgow. All this shows that the Telephone Committee of the Corporation have not as yet really faced the question of finance."

If this conclusion of the "judge"—for judge he was in this case—means anything, it means that Mr. Bennett's estimate was just what Mr. Bennett says, an estimate for the purpose of showing what the system then in existence ought to have cost; and that Mr. Bennett's own estimate, when made, would be for an expenditure, not of £97,000 or £100,000, but about four times that, or £400,000.

Just one word as to Mr. Webb's play of words on the question of similarity or similar. It will be time enough to discuss whether I ought to have said "identical" rather than "similar" when the more important subject is decided, but I used "similar" because I did not mean "identical," only approximating to that which existed something almost or quite equivalent to what existed, as regards results to be obtained, though not absolutely identical as regards every detail of equipment. Neither Mr. Bennett, nor the "Town Clerk," nor even Mr. Webb would obtain tenders for identically the same things that existed, a close approximation being all that was required for the purpose in view. I suppose the difference between the "metallic circuit underground" and the "overhead single-wire system" was discounted for what it was worth by the judge. My point, however, is a very different one. The estimate—"identical, or "similar," or "approximate," whatever word be used—was not for work to be done, but for another purpose, to get, if you like, "approximately at the cost," "near enough for the purpose in view" (which phrases are glosses on Mr. Bennett's words, "ought to have cost"—of "the then existing telephone system." The idea so evidently conveyed to the judge was that Mr. Bennett's proposals, if ever formulated, would cost nearer

Digitized by Google

£400,000 than £100,000, and that those proposals were not on the same lines as those on which the estimate was founded. If this is the correct view, and, as I say, it has the imprint of the "judge" who heard all the evidence, this well-discussed estimate has no more to do with the actual work carried out than had Zenophon.—Yours, etc., W. O. T.

[We are not altogether satisfied with the use of such words as "stupidities." Mr. Webb is entitled to say what is his interpretation of a certain estimate, and Mr. Bennett is entitled to deal with that interpretation in two ways: (1) With a direct negative; if that is rejected, and no further evidence be forthcoming, the world must judge of the relative credibility of the opponents. (2) To reinforce the negative with variant interpretations by others in a position to judge as well, or better, the facts of the case as his opponents. Mr. Bennett has given the direct negative. His assertion is supported by Mr. Jameson's report, also by the remarks of Colonel Slacke, which he says deals with the same question, though the excerpt he gives from the Hull paper leaves the exact question to which Colonel Slacke referred in doubt. It requires Mr. Robb's statement of the previous day.—ED. *E. E.*]

ARTIFICIAL LOADS.

SIR,—Referring to Mr. Davis's letter which appeared in your issue of 12th inst., I beg to say that I quite agree with him, that it is the publishing of one's experience, together with the general details and results obtained, that does much towards forwarding the general knowledge, but should like to remind him that exchanges of opinion, together with discussions from others who can claim to have had experience in the subject, are certainly healthy points, and must also go far toward assisting in the above object. Therefore, it was only with this object in view that I endeavoured to point out that although the method he used was certainly an improvement upon any arrangement of tubs or wire resistances—and I have not the slightest doubt but that the tank he mentioned proved itself both useful and satisfactory—there are still points which I thought might be improved upon, some of which have been mentioned, points which I have found by experience, and which have also been proved by other engineers, to be quite correct.

With regard to the question of earthing the tanks, I may say that there is nothing in this method that would specially recommend its practice. Personally, I have always considered it an unmerciful test upon the insulation of either dynamo or motor, especially in such places as a large engineer's testing department, where pony brakes, water brakes, surface-condensing plants, water-resistance tanks, pumps, and cylinder drains are all helping to saturate the atmosphere with moisture, which, settling on the insulation, does not tend to strengthen or increase its resistance. Besides, no practical engineer would think of running the machine under full load at the maximum voltage in order to test the insulation. Better by far test this with the proper instruments before starting up. Generally speaking, when a set is run for some hours on trial, it is for the purpose of testing the combined efficiency and general behaviour of same with regard to the rise in temperature, etc., and not so much for testing the insulation, because should there be any weak point in the insulation not detected before starting up it, is almost certain to burn up and probably ruin half the winding long before you can shut down.

Mr. Davis and "A.M.I.C.E." seems to be under the impression that the chief reason for using the earth system is to prevent serious results from shocks, which impression is entirely wrong, as it can be shown that the risk from shocks is far greater, when using the earth system, than when completely insulated from all earth circuits. With regard to the lives of the attendants being at stake, this is certainly an exaggeration. My advice is to see that all connections are both mechanically and electrically made before thinking of coming up under load, and not to allow any assistant to attempt to complete any unfinished work. Whilst the machine is on load there is no reason for having to handle any part of the circuit beyond adjusting the brushes or working the switches, which should, of course, be properly protected.

What I wished to point out regarding the use of chemicals was, that in order to get a very steady run it is necessary to keep the conductivity of the water perfectly constant, and this can only be done in two ways—viz.: (1) by keeping the temperature of the water constant by circulating a sufficient volume; and (2) by drawing the circulating water from some large source, such as a canal, of course taking great care that the suction pipe is right away from any works drains, and so prevent any possibility of contamination. Mr. Davis mentioned that occasion may arise when it would be an advantage to put a small quantity of chemicals into the tank, in order to get the last few amperes and so build up the full load, but this would be practically useless with a heavy circulation of water. What I would strongly advise him to do would be to increase the cross-section of the water by increasing the depth in order to build up the load, and this could easily be done with a suitable arrangement for adjusting the overflow. This, together with an arrangement for varying the distance between the electrodes by lowering the one tank into the other, would give his tanks a wide range of adaptability, and hence do away altogether with the need for chemicals. I should like to ask Mr. Davis to look up the back numbers of this paper for the month of March, in which he will read that a representative of a very large firm—makers of high-speed engines—read a paper on Feb. 17 before the Institution of Electrical Engineers, in which he clearly told the members that for some years past they had only used canal water for their tanks, and that on no account were chemicals allowed to be used. Then, surely, if a works of such magnitude, with a large testing department constantly making tests, find the canal water quite a success, I do not think that either Mr. Davis or "A.M.I.C.E." need have any fear in using it, providing proper care is exercised when deciding upon the position of the suction pipe.—Yours, etc, YRREB.

SIR,—Referring to the remarkable letter by "A.M.I.C.E." in the *Electrical Engineer* for Aug. 12, which is an outburst of nothing—at least, not of importance—and is also quite devoid of any real practical help upon the subject. In other words, it is a clear admission of carelessness and inexperience with these matters.

Every one of his remarks quite confirm this conclusion. Take, for instance, that part in which he states, "Mr. Davis points out the desirability of doing without acid or alkalies to reduce the resistance of the water, and emphasises the alternative method—a rapid changing of the water." Of course, meaning to say that, instead of using acids or alkalies to reduce the resistance of the water, he would effect a rapid changing of the water to produce this. Now, if he were running a dynamo set on part load, and wished to increase the load by lowering the total resistance of the tank, surely he does not mean to say that a rapid changing of the water would do this. If so, then I venture to say that he is entirely wrong with such an impression; what it certainly would do, if anything at all, would be to lower the temperature of the water in the tank, and by so doing, considerably increase the total resistance of the circuit, which in turn would take off greater part of the load, and therefore upset everything.

Then, again, it is quite absurd to attempt to show that a large body of water such as a canal is likely to instantly change in its physical properties or conductivity, and so bring about such a violent change in load such as he speaks of. But what it really does show in the remarks is that someone had evidently fixed the pump suction pipe very near the drains of some other works, and that any stream of impurities which may come down during the test he got the full benefit of. Which would, to say the least, be gross carelessness on the part of the one responsible for selecting the place to fix the suction pipe.

Then, again, the film of oil, and his impression upon the effect of such, is radically wrong, as anyone who has had occasion to use condensed water for the resistance or test tank, or who may have studied the physical change that

Digitized by Google

would be produced by the addition of oil into water, would know that it is quite different in effect to that he mentioned, and cannot be responsible for the great fluctuation in load of which he has experienced. It rather suggests that "A.M.I.C.E.," or someone else, may have been oiling the overhead gear, and quite carelessly dropped the oilcan down between the electrodes in the tank, which would doubtlessly cause such a great change in the load he speaks of. If "A.M.I.C.E." is anxious to become a successful engineer, he must drop all slipshod methods, and carefully consider what he is going to do before he starts, provide proper tanks with ample supply of circulating water, suitable arrangements for varying the load, avoid all chemicals, and, above all, carefully avoid placing the pump suction pipe up the drain of some chemical works. If he will do this, he will meet with better results The indicator cards may not be quite so picturesque as before, but from an engineer's point of view they will be much better.—Yours, etc., YRREB.

THE HOPKINSON TEST AS APPLIED TO INDUCTION MOTORS.*

BY W. E SUMPNER, D SC, AND R W. WEEKES, M.I E.E.

The late Dr. Hopkinson was, as is well known, the first to suggest a method of testing direct-current dynamos by arranging similar machines in pairs so as to circulate the power, the portion of the power wasted being supplied from some external source. The method and its advantages are well known in regard to direct-current machinery. The principle of the method is, of course, applicable to any form of apparatus capable of transforming energy in a reversible manner. It was applied to the testing of alternating-current transformers by one of the writers some years ago, and it has since been utilised for the testing of alternators. The application to three-phase machinery involves some special points, and the writers, who have lately tested a number of induction motors by this method, have found it so satisfactory that it seems desirable to draw attention to the experimental details involved in the test.

The two similar machines have their stators connected with the mains, while their rotors are belted together. Switches must be used with the stator connections if the rotors are of the short-circuited type, but are unnecessary if the rotors are supplied with starting resistances. The connections must be such that the belt is driven in the same direction whichever motor is started. The pulleys on the rotors must be of different diameters, since one rotor must run above and the other below the synchronous speed The ratio of the diameters must be such as to cause the right amount of slip for the load required, assuming the rotors are to remain short-circuited during the test. If the slip of each motor is 3 per cent. at full load, and if 12 per cent. of the load is lost in each machine, the overload of one machine will be approximately 24 per cent, corresponding with a slip of $3\frac{3}{4}$ per cent.; while the other machine, working as generator, will give out full load and have a negative slip of 3 per cent. The pulley diameters must thus differ by $6\frac{3}{4}$ per cent., assuming no mechanical slip between the belt and the pulley, or if 1 per cent. be allowed for this, the pulleys must differ by about 8 per cent. in size. With such pulleys the machines, when switched on to the mains, will be subjected to a perfectly steady load admirably suitable for a long run on load. But with given pulleys the load cannot be adjusted or altered unless resistance is put in the rotor circuits. This can easily be arranged by using low-resistance connections between the rotor slip-rings and the short-circuited starter, or, better still, by using, when available, a rotor starter which can stand the passage of the load currents through the rotor circuits. By adjusting the position of the starting switch the load can be then adjusted to any desired amount, if the rotor pulleys have been chosen sufficiently different in size to fully provide for the slips required. The losses in the rotor resistances are very small, and can in most cases be neglected. They are, however, easily measured, and should be subtracted from the power taken from the mains in order to arrive at the total losses in the two machines and in the belt drive.

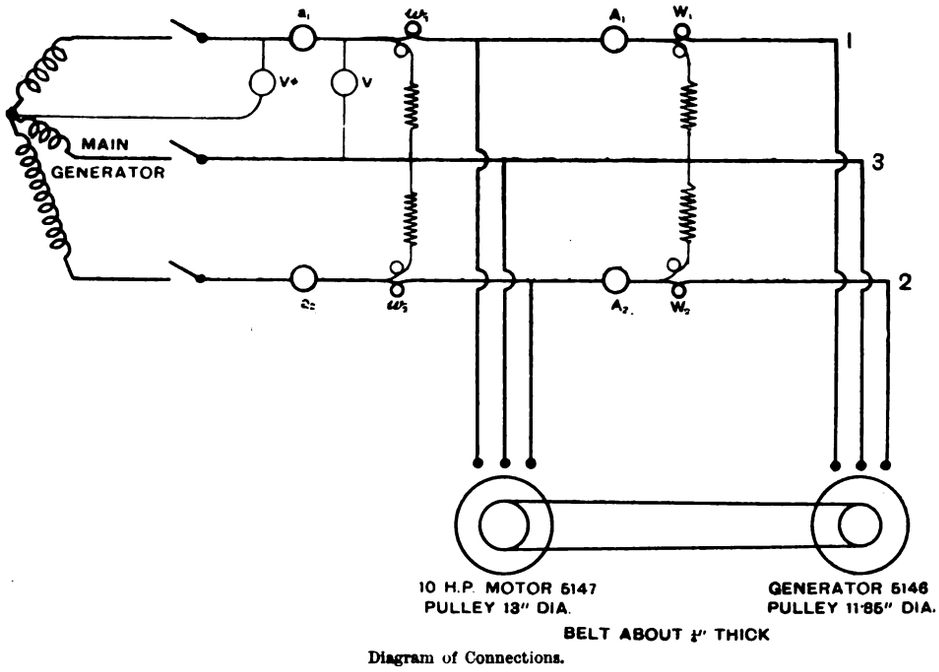

Diagram of Connections.

Another method of adjusting the load consists in altering the voltage of supply. For given values of the slip the torque of the machines, and therefore the load, is proportional to the square of the voltage.

The arrangement of instruments and circuits is shown in the diagram. The power, *w*, taken from the mains must be measured, and also the power, W, in the circuit between *one* of the machines and the mains. The machine used as motor, of course, takes the greater amount of power, and if W refers to the power given out by the generator, $W + w$ is the power supplied to the motor. Otherwise the difference between these quantities is the power given out by the generator. The load of each machine and the losses in the two are thus determined, and the efficiency can be obtained in the same way as for direct-current machines. In regard to the measurement of power, it will be found sufficiently accurate for all commercial measurements of efficiency to use the single-wattmeter method (which assumes that the load is balanced between the circuits) and treble the reading of a wattmeter with its current coil

* Paper read before the British Association at Cambridge.

placed in one circuit, and its volt coil connected between this and the neutral point. It is, of course, more accurate to use the two-wattmeter method as sketched in the diagram. The connections are then less simple, but from the ratio of the two-wattmeter readings the power factor of the circuit can be determined independently of the ordinary method of comparing the watts with the volt-amperes. Care must be taken in reading the wattmeters in the main circuit if the two-wattmeter method is used, since one of these readings will be negative owing to the low power factor of the current taken from the mains. A curious point about the test is that the machine used as generator produces current of about the same power factor as that of the current supplied to the motor, while the current supplied by the main circuit consists of the difference of the power components of the machine currents, together with the sum of the inductive components of these currents. The result is that the power factor of the current from the mains is very low, only about one-third of that of the machine currents. It thus happens that while the power taken from the mains may be less than one-third of that circulating round the machines, the current from the main generator is about equal to and may exceed that passing through the machines, a striking contrast with what happens in the corresponding test of direct-current dynamos.

The slip of each machine can be determined most conveniently and accurately by measuring the frequency of the rotor currents by suitably shunting any ordinary low-reading direct-current voltmeter to the slip-rings of the rotor. The period of the slow oscillations of the pointer can be measured with greater accuracy than the frequency of the main circuit currents. The ratio of the two frequencies is, of course, the slip of the machine.

A most interesting point in connection with the tests is the possibility of determining the belt losses, and the value of the mechanical slip between the belt and the pulleys. The losses due to the belt drive are caused by (1) extra bearing friction and in bending and driving the belt; (2) heating of the pulleys due to belt slip. The former loss (1) can be measured by reading the wattmeter in the main circuit, firstly, when only one machine is in circuit and driving the other by belt (with its stator excited, but with its rotor open circuited), and, secondly, when both machines are running light with the belt off. The difference of the two readings gives the belt driving losses. The latter loss (2) is determined by the ratio of the circumferential speeds of the two pulleys. This is a quantity difficult to determine with any accuracy in ordinary belt drives. The above test seems specially suitable for determining its amount. The ratio of the rotor speeds is

$$\frac{F + g}{F - m},$$

where F is the frequency of the current from the main generator, m that of the currents in the motor rotor, and g that of the currents in the generator rotor. Now, m and g are quantities which can be very accurately determined, and are each small compared with F, so that, although F cannot be determined with such great accuracy, the form of the above formula shows that the ratio is not appreciably affected by small errors in F. Thus the ratio of the rotor speeds can be very precisely measured. To obtain the ratio of the circumferential speeds of the pulleys, we have merely to multiply the above number by the ratio of the pulley circumferences, a quantity which can be accurately determined. A good experimental means thus exists for finding the actual values for the slip of belts under various conditions.

A number of experimental results obtained in testing various motors by this method have already been published by the authors in the *Electrical Engineer* for June 17 last, and some of them are reproduced in the appendix. Experience with the method shows that it possesses all the advantages associated with the Hopkinson test of direct-current machines. If anything, the experimental arrangements are easier to make with induction motors than with

dynamos, while the accuracy of the method is a greater boon with three-phase plant than with direct-current machinery, owing to the greater complication of the testing, and to the fact that alternating-current instruments are not so satisfactory as those for direct-current.

APPENDIX.

The accompanying four tables give the results obtained by these methods of testing three-phase motors. The trials were made at the Witton Works of the General Electric Company during April and May last. It is also worthy of note that the power factors calculated from the ratio of the two-wattmeter readings agrees fairly well with the ratio between the apparent and true watts. The power factors given are those obtained from the ratio of these wattmeter readings.

LETTERS FROM AN OLD HAND TO A YOUNG ONE.

V.—ON THE INTELLIGENCE DEPARTMENT.

My Dear Young 'Un,—I assume that you are going into electrical engineering in order to earn your living. Most fellows do, and those wealthy bounders who are in it for the fun of the thing ought to be dropped on for the nasty way they have of cutting prices. Now, it is an unfortunate fact that modern business is conducted on the lines of the American duel. Two Yankee gentlemen desirous of conducting an affair of honour, select their favourite six-shooters and enter a wood from opposite sides. They then stalk each other until one of them loses all further interest in the game. The only thing the outside world knows about it is that two men went into the wood and only one came out. The late lamented was the one that didn't see quick enough.

At college you don't get much practice in keeping your eye open. You get facts and figures flung at you in such an insistent manner that you tend to lose whatever talent you had for nosing things out for yourself. When you get into actual practice you will find very few people who are inclined to give you information gratis. No one is pleased to see someone else getting on too fast. You will probably discover that most useful information is carefully tucked out of sight by those who know. You will be baulked in getting at it, and you will have to guard against being stuffed up with misleading statements.

You cannot, therefore, begin too soon the habit of putting two and two together and totting them up. In other words, you must start an intelligence department for your own benefit. When, therefore, you have attended the last college lecture of the day, don't think you can go off and play cricket. Neither should you limit yourself to going home to stew preparation. Go off on your own occasionally, and explore the neighbourhood for anything engineering. Stand on the kerbstone while the road is being pulled about for the electric trams. Wander into the railway station, and get a look at the underneath of an engine. Hang about the door of the blacksmith, the cooper, the timber yard—anywhere where there is work going on—and see all you can. You will get hold of many things not written in books.

Digitized by Google

If you can manage it, get into conversation with any engineer you come across, whether he be of high or low estate, and cultivate the use of the leading question. There is an art in asking questions which can only be compared to the knack of milking a cow. An expert dairymaid can handle a cow so persuasively that the animal positively smiles with pleasure as it yields the milk. A novice will probably induce the beast to kick the pail into the back end of last week and push the operator after it. In the same way, one man can get information from you and make you proud to give it; another makes you yearn to give a gymnastic display on his person because of his impertinence. No one can explain the difference—it is just a question of trying till the gift comes. Only two general rules can be given: Don't be shy—delicate feelings are of no commercial value, and the actual risk to life through asking questions is very small. And don't be silly—don't ask before you think. You know that in boxing, one well-delivered upper-cut does more good than any amount of wild hitting. There is generally one question which will induce your *vis à vis* to tell you just what you want to know. Ask that question and no more—and don't ask it as if your soul's salvation depends on the answer, if you particularly want one. Slip it out easily, as if you are just humouring your acquaintance by keeping up a conversation. He will then be off his guard, and may give away something which on second thoughts he would rather have kept dark.

You will find that official information is often not much use. It may be strictly true in letter, but misleading by its paucity. An official's statement is limited by two things—the facts he doesn't know himself (for very often the complete knowledge of the ins and outs of a job is limited to subordinates in immediate charge of the job), and the facts he doesn't want you to know. If he were talking freely, as man to man, he might be able to tell you things which his position with respect to his employers prevents him as a man of honour from divulging. If you want to get a plain, unvarnished account of anything, go to people who know but aren't responsible. For example, if you want to know how a certain type of engine really runs, don't go to the chief engineer, but to the driver.

Make a study of keeping yourself *au courant* with all information available. Draw up a list of your sources—such technical papers as are suitable to your calibre, any engineering societies you have the opportunity of joining, any friends in engineering firms you can see or write to, any shops which you can visit. And take a look at your list occasionally to see whether anyone or anything is being neglected. You will thus surround yourself with a network of "feelers," by which a disturbance in any part of your field of activity will be at once detected by you. In my earlier days I belonged to a private information club kept up by six young fellows in different firms, who wrote month by month a record of any new ideas they had seen in their work, and passed round these notes and sketches as a sort of circulating library. I don't know how our employers would have liked it had they known, but it was very useful to us—it kept us in touch, it made us accurate observers, and it widened our field of observation.

Now, I want to shatter your faith in human kind by impressing on you that you can't go through life in our profession in a spirit of blind amiability. That attitude is one of the chief reasons why so many splendidly-educated men—fellows who have had good chances—are occupying badly-paid positions. On the assumption that the world is just, they have jumped at the conclusion that the way to get on is to get more internal knowledge. Nothing of the kind! The men who get on are those who keep their hand on the feeler network and respond smartly to its indications. When a country goes to war it not only wants to know its own resources, but what the enemy is going to do. The Japanese soldier not only carries a rifle and ammunition, but he has a field glass to see what the other fellow is doing. When two fencers engage, they watch each other's eyes to see the quick glance at the part which it is intended to attack. Your "intelligence department" must be directed not only to the collection of facts, but to the observation of the moves on the chessboard. The best jobs are seldom advertised. Even when they are you may be sure that they have been watched by more than one intelligence department for some time previously.—Yours,

THE OLD 'UN.

POWER—ECONOMICAL AND OTHERWISE.

BY CAPTAIN F. S. N. MACRORY, R.E.

"High Pressure"—that is the watchword of success in these modern times. It is applicable not alone to mental activity, but also, and with as much force, to the successful working of all mechanical and industrial problems of the present day. Our fathers walked—we must run. The future generation will probably fly. But let us to our case in point without further preamble—a sign in itself of low pressure.

The example is an Irish oatmeal mill, one of the few survivors of the good old times. For over 40 years the power necessary to drive this mill had been furnished by a low-speed, low-pressure, double-cylinder steam-engine, of a type well known and justly esteemed in the early sixties. The nominal horse-power (hideous and meaningless term) was 35, and the power actually developed might have been anything up to 60 h.p. A good old engine in its way. Built for everlasting wear, old fashioned, never in its easy-going life exceeding a boiler pressure of 60lb. to the square inch, and having even that reduced to 50lb. in its latter days, it can easily be imagined that it had a somewhat abnormal appetite for coal. This appetite increased with age. It made light (or more correctly speaking, power) of a daily meal of 25cwt. of good Scotch steam coal. Without going into details of the milling machinery, we may assume that the full amount of power required to drive it was 45 actual horse-power. So that the coal consumption was out of all proportion to the work done. Many expedients were tried with a view to reducing this extravagant consumption, but with little success. Finally, when the question of a new steam-boiler began to loom in view, it was determined to relegate the entire power plant to a well-earned rest, and to replace it with something of a more up-to-date type.

Electric transmission from a source of water power three miles distant: new steam engine and boiler: oil engine: gas-engine: the choice lay between these four. After due consideration of the *pros* and *cons.* of each system, the decision fell on the last one. To work a large gas-engine with town gas is, however, by no means the height of economy. Nor, in small country towns, is the supply usually all that can be desired. Therefore, a gas-producing plant was also decided on. Of these there are now many varieties on the market. But the latest type, known as the suction plant, seemed to offer so many advantages over the older form, that it was resolved to give it a trial. In this type of plant, the gas necessary to drive the engine is sucked in by the latter itself, the out-stroke of the piston producing the requisite vacuum to draw the gas into the cylinder. No gasholder is, therefore, required, and the pressure of gas in the apparatus is below that of the atmosphere when the engine is at work. The small steam-boiler required in the case of an ordinary gas-producer is also dispensed with in the suction type of plant, where the generator itself furnishes the steam requisite for the gas production.

The improved Dowson suction plant was accordingly installed as being the original, and probably as good as, if not better than, any of the later types. This plant is very simple, and consists essentially of (1) a generator or furnace burning anthracite or coke "nuts"—*i.e.*, cubes about 1in. square; (2) a water jacket for cooling the gases; (3) "scrubber" filled with coke moistened by a trickle of water, which serves to purify the gases; (4) a second "scrubber" filled with sawdust, which dries and further purifies the gases; (5) an expansion box near the engine, taking the place of the gas-bag provided with ordinary gas plants of this nature. The plant is started by blowing a jet of air through the fire in the generator till the gas is rich enough to burn, after which the engine is started, and itself keeps the air draught (now mingled with steam) going auto-

Digitized by Google

matically. As for the gas-engine itself, all the leading makes are probably equally good, though differing in details. In the present case a 50-h.p. "National" engine was selected, as the makers of this engine have had great practical experience with the various forms of Dowson plants, and, in addition, turn out a most efficient and highly finished engine.

Next with regard to transmission of power. It must be borne in mind that a gas-engine, with its one power impulse in every two complete revolutions, is a very different affair to a steam-engine with its two or even more power impulses to every revolution. It was evident that the old system of driving by means of direct spur gearing would have to give way to a belt drive, in order to take up as much as possible the violent shocks of the impulses. And a 10in. belt, of suitable strength, driving from a 3ft. 6in. pulley on the gas engine to a pulley of similar size on a countershaft 23ft. distant from the engine, made a most efficient and smooth-running substitute. Fast and loose pulleys were fitted on the countershaft to permit of the engine being started light and the load being applied after the proper speed had been attained, for a gas-engine, unlike a steam-engine, cannot start under its full load. Another 10in. belt, in conjunction with a suitable arrangement of pulleys, transmitted the power to the main driving shaft, the arrangement of which remained unaltered. Yet another belt on the countershaft served to drive the remainder of the mill gear, and it may be mentioned now that this system of driving entirely by belts has proved eminently satisfactory. A little dressing on the belts occasionally obviates all tendency to slip—that bugbear of the belt user.

And now to revert once more to the gas-engine. It was resolved to have electric ignition, instead of the older type of firing the charges by means of a porcelain tube heated by an independent supply of gas. The electric type consists of a small Simms-Bosch magneto, having permanent magnets and an oscillatory armature. When the engine is working, a sharp rocking movement is imparted to this armature by a small stud on the cam shaft at the right moment for firing the charge, and an electric spark is thus produced inside the combustion chamber. With regard to cooling the cylinder of the engine. In most cases a supply of water-tanks are required for this purpose, but in the present case these were dispensed with, as a source of running water was available. The water was simply led by pipes in at the bottom of the water-jacket and out at the top. By regulating the supply the cylinder could be kept at any desired temperature. The "National" self-starting device consists of a small hand-pump fixed on one side of the cylinder, by means of which a starting charge of explosive mixture is forced into the cylinder, and the magneto lever being then oscillated by hand, the first explosion takes place, after which the engine takes up the running.

We have now reviewed the whole of the new driving plant. Let us pause a moment to consider the relative space required for both the old and the new systems. In the case of the steam-engine an engine-room 29ft. by 11ft was required, while the boiler occupied a space of 25ft. by 9ft.—in all, a total space of 558½ square feet. In the case of the gas-engine, an engine-room 18ft. by 13ft. was found ample, while the gas-producer plant required a space of 15in. by 10in.—in all, a total space of 384 square feet. Thus the space required for the new plant is only about two-thirds that for the old one. There is an additional saving of space, as no steam stack is now necessary.

We next turn to the relative fuel consumptions of the two systems. The average amount of this for the steam plant under full load, worked out at 25cwt. per day of Scotch steam coal, costing about 17s. per ton—that is, assuming the full load to be 45 actual horse-power, and the working day to be 10 hours in length, the power in this case cost ·566d. per horse-power hour. Under the same conditions, the fuel consumption of the gas-engine never exceeded 5cwt. per day, the fuel being Welsh anthracite "nuts" or "peas," costing about 24s. per ton delivered. From this, the power works out at ·16d. per horse-power hour. This shows a very remarkable saving, and it would therefore appear certain that, as far as actual cost of running goes, nothing but water power has yet been invented which can compete with such a system of power production as the one under consideration. Even the latest and best of steam-engines would probably cost twice as much in coal to generate the same power.

With regard to the actual starting up each morning and management during the day of the gas-producer and engine, the work required is simple enough when things are going right (that "when" is an important point, as will be shown later on). The daily routine is something as follows: The fire in the generator having been left slowly burning all night (which can be done every night except in the case of the periodic cleaning of the generator), the engineer on arrival proceeds to close up the grate doors and to fully open a waste cock on the gas-pipe. He then puts in a charge of about eight bucketfuls of coal, and starts blowing the hand fan. In about a quarter of an hour the gas produced will be rich enough to burn, and, when this is so, the waste cock is closed, and the gas produced is then forced through the cleaning apparatus of the plant to the engine. In a few minutes all the air will have been expelled from the pipes, etc., and the gas will burn at the engine test cock. About 60 strokes of the hand pump are given, and the engine is started in the usual way. Once started and the proper steam attained, the belt can be shifted from the loose to the fast pulley, and no more attention is required, except to see that all lubricators are working properly on the engine, and once in every three hours to add a few more bucketfuls of fuel to the generator. The whole operation of starting occupies less than half an hour, and is only increased by a few minutes on those occasions when the fire in the producer has to be lit and the apparatus started up from "the cold."

Lastly, let us review what is perhaps the most important point of all, simply for the reason that it is only discovered by experience, and is looked in vain for in the makers' catalogues. In other words, let us go into the drawbacks and disadvantages of the whole system. Its advantages are so very apparent that one naturally wonders why it is not universally adopted by all users of power. Well, there is undoubtedly one great drawback to gas-engines worked by producer gas, which at present precludes its adoption in a vast number of cases. As now made, at all events, it has not by any means attained to the same pitch of almost absolute reliability which steam, electric, or water power have. There is no doubt on the subject—it is tricky, deuced tricky. Inexplicable breakdowns may and do occur at the very moments when one least desires or expects them. Of course, skilful and thorough attention to details largely obviates this risk, but it is always there to some extent. And in the case of large factories, etc., which employ a great number of hands, even a temporary breakdown, which will throw all these hands out of work for the time being, is a most serious affair. Lack of absolute reliability—that is the drawback which in so many cases counterbalances the many great advantages of the gas-producing power system. We never get Perfection (with a big P) in this world. Our object is to get as near it as we can. Such little things will upset the equilibrium of a gas-engine—things that, once located, can be often put right in less than a minute. But the locating is the trouble.

There was a little girl of whom it is written that "when she was good, she was very, very good, but when she was bad she was horrid." Even so is it with oil and gas driven engines, not to mention their relatives—those most notorious offenders of all, automobiles. Yet all these things have come to stay (or, more correctly, to go), for in their better moods they are so fascinating that one is compelled to overlook their occasional lapses from virtue; in fact, one sometimes loves them all the more for these very lapses.

But now the worst is out, and be not discouraged too much by it. Let us see how we may, as much as possible, avoid these occasional breakdowns. With regard to the producer itself, attend rigidly to the makers' instructions. Clean the generator thoroughly, and rake out all clinker at least once a week. Clean all the pipes and water joints of the rest of the apparatus at least once a fortnight. Renew the coke in the coke scrubber not seldomer than once in three months, and perform the same operation for the sawdust scrubber every month. Do not go on the principle

Digitized by Google

of letting well alone till a stoppage does occur. Prevention is better than cure.

With respect to the engine, it must be borne in mind that producer gas is, after all, a comparatively new thing, and its effect on the valves and interior economy of gas-engines is still, to a certain extent, unknown. The trouble with it is that, in spite of all cleaning operations, it still remains a much dirtier article than town gas, and tends to foul everything it comes in contact with to a proportionate extent. In the case I am dealing with, it was found necessary to clean the exhaust valve of the engine twice a week—just four times as often as recommended by the makers—otherwise, explosions in the silencer, weak and irregular running, and, perhaps, total stoppages occurred. The operation can, however, be satisfactorily performed in an hour. Once a fortnight seems sufficiently often to clean both the gas and air valves. The electric ignition system requires attention twice a week, in order to prevent the sparking device inside the combustion chamber from sticking. In addition, it is, of course, necessary to keep all insulated parts in good order and terminals clean. But, on the whole, this part of the plant is wonderfully free from trouble, if a little intelligence be exercised in its management. There are also many other little points which each user finds out for himself by actual experience—not too bitter, let us hope.

Depreciation of the plant due to wear and tear has not yet been touched on. A fair estimate would probably be 10 per cent. per annum on the initial outlay—about the same as on a steam plant of similar power. The upkeep of a gas-engine is slightly higher than that of a steam-engine, but the upkeep of a producer plant will certainly work out considerably lower than that of a steam-boiler.

So the sum total of the whole matter seems to be this: producer gas as a source of power is very highly to be recommended where an occasional stoppage in the course of a day's work is not of vital importance, but in all other cases it has hardly yet attained to a sufficient pitch of reliability to warrant its introduction. It has, at all events, a great future before it.

BRIDGEND ELECTRICITY ACCOUNTS.

The accounts of the Bridgend electricity department for the year ended March 31, 1904, show a total expenditure on capital account of £6,153. Appended are abstracts of the revenue account, general balance-sheet, etc.

REVENUE ACCOUNT.

Dr. Expenditure.	£	s.	d.
S.W.P. Co. for current supplied	442	2	7
Distribution of current	19	17	8
Attending and repairs to public lamps	41	19	0

TRADE NOTICES AND NOVELTIES.

The Utilisation of Waste Heat from Coke Ovens.

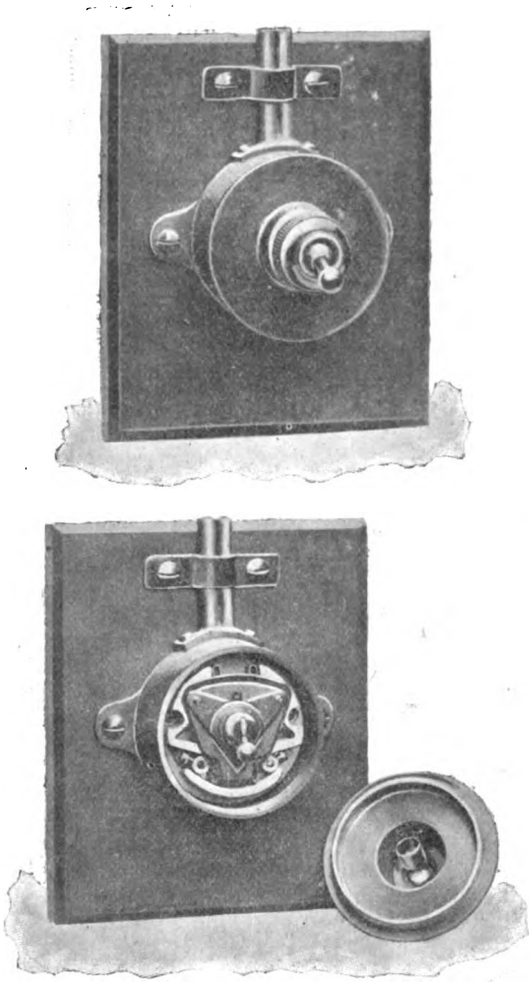
The Stirling Company, of 53, Deansgate-arcade, Manchester, have issued a pamphlet giving particulars of the performance of one of their standard boilers fired with waste heat from "beehive" coke ovens, and figures for comparison with Lancashire boilers working under similar conditions. These figures show that although the inlet temperature of the gases at the point where they enter the boiler setting was only 1,700deg. F., not only was the full normal duty obtained from the Stirling boiler, but an evaporation of 1·71b. of water from and at 212deg. F. per pound of coal coked in the ovens was obtained, as against a figure of 1·331b. of water evaporated by the Lancashires, or a difference in favour of the water-tube boiler, if expressed in terms of the amount of water evaporated by the Lancashire boilers per pound of coal coked, equal to 28 per cent. Our attention is further called to the prominence which is now being given to the question of utilising waste heat from coke-oven plant generally by some of the leading electrical power supply corporations. For example, the Newcastle-on-Tyne Electric Supply Company have put down a plant at Blaydon Burn, where they are utilising the waste heat from a battery of "retort" type coke ovens. This plant, it is stated, is being run, practically speaking, as a battery, and at a cost per unit generated which has never before been approached in this country.

Watertight Tumbler Switch.

To get over the difficulty which has always presented itself when using tumbler switches for outdoor work or in exposed positions where moisture is present, the General Contracts Company, Limited, of 1, Fenchurch-avenue, E.C., and 102A, Charing Cross-road, W.C., have recently put on the market the form of their patent "Strut" switch illustrated herewith. To facilitate manufacture, their standard type of switch is used complete, secured in the metal box either with or without the cover, as may be desired; while to retain the full advantage of the tumbler action, and at the same time produce a switch that is absolutely watertight, a second dolly is introduced, working

Digitized by Google

in a ball-and-socket joint in the cover of the watertight box. This second dolly carries a cupped end, which fits over the ball of the permanent switch dolly, thus forming a smooth working joint between the outer dolly and the switch lever. For convenience in coupling up, the wires are carried through glands in the side of the box, so arranged as to give sufficient length of wire to allow the switch being removed for making the connections, space being allowed in the bottom of the box for the slack wire to stow when the switch is fixed in position. The additional dolly and outer cover being concentric with one another, admits of the cover being unscrewed with the switch in any position, and as there are no small screws or loose parts in connection with this portion of the case which have to be removed when making the wire connections, and so interfere with the adjustment of the watertight joint, the switch becomes one of the simplest and most effectual watertight switches on the market. Moreover, it is claimed to be the only real watertight tumbler switch



Watertight Tumbler Switch.

which carries the working tumbler unprotected. We recently had an opportunity of examining this switch, and were perfectly satisfied with its action and construction. It may be added, in conclusion, that the switch is made up to take any form of gland or other tube connection, and is manufactured under the company's patents.

"SS" Intercommunication Telephones.

The General Electric Company, Limited, Queen Victoria-street, E.C., have recently introduced a new type of intercommunication telephone embodying many important advantages, chief of which is that it ensures an absolutely secret service while in use. In design the instrument is somewhat of a departure from the usual form, and it combines the very latest developments made in telephone work generally. Referring to the accompanying illustrations, it will be observed that there are a number of drop indicators corresponding with the number of lines, and immediately below these are the "jacks" or plug sockets. A connecting plug with a length of flexible cord is also provided, which is inserted into any "jack," according to the number of the line it is desired to communicate with. When a call is made the indicator corresponding with that particular line falls, denoting at once who is calling. Should the office be vacant when the call is made, this indicator serves a very useful purpose, for it clearly shows a person on returning that a call has been made and who it was that "rung up." Two stations cannot be accidentally rung up at one time by careless placing of the switch. It is, therefore, impossible for a third person to overhear the conversation, or to interrupt in any way whatsoever; moreover, inductive effects are eliminated with this particular type of instrument, and all chances of leakage disposed of by the adoption of a metallic circuit throughout. This telephone has been named the "SS." It can also be used as a central-station instrument for intercommunication between outlying stations. Should these stations

The "SS" Wall Pattern Telephone.

be a considerable distance away, instead of running a cable of the necessary size to each, a single pair of lines could be used between the instruments at the outlying stations and the central station, thus minimising the cost of wiring. If the "SS" telephone is used for this purpose it is provided with a pair of plugs which enables the calling station to be connected

The "SS" Table Pattern Telephone.

through to any other station on the system. The reputation of the makers for the class of apparatus in question is sufficient guarantee of its excellence, both as regards construction and careful design. Further particulars, together with a diagram of connections, will be found in the G.E.C. pamphlet (K)1,066.

LEGAL INTELLIGENCE.

DEBENTURE-HOLDERS' ACTION.

At a vacation sitting of the Lancashire Chancery Court at Liverpool last week a debenture-holders' application was made in the matter of Krauss and others v. the South Lancashire Electric Traction and Power Company and others.

Mr. Preston, for the applicants, said that this was a debenture-holders' action for the appointment of a receiver and for enquiries and accounts. The company did not oppose, but the trustees had put in a defence.

Mr. Stewart Deacon, for Sir William Forwood and Mr. W. S. Barrett, trustees for the debenture-holders, said the only point his clients made was as to the remuneration to which they were entitled. The arrangement was for £100 a year each, and as these proceedings might be prolonged they wished to have the question of their remuneration determined.

The **Deputy Vice-Chancellor** made an order in the terms of the proposed minutes, with the addition of an enquiry as to the trustees' remuneration.

COMPANIES' MEETINGS AND REPORTS

DUBLIN AND LUCAN TRAM.

The half-yearly meeting of this Company was held at Dublin on the 18th inst. Mr. William Mooney, J.P. (chairman), presided. The report appeared in our issue of 15th inst.

The **Chairman**, in proposing the adoption of the report, referred to the great progress the Company had made since the construction and electrical equipment of the new line, and to the circumstances that had prevented, notwithstanding their success, the payment of a dividend on the ordinary shares. The expense of constructing the new line and of its electrical equipment had doubled their capital. The holders of debenture and preference shares had a priority to the ordinary shareholders. Their receipts for the last completed year (1899) under steam haulage were £4,058. 9s. 10d., as against £6,365. 15s. 3d. for the year ending June 30, 1904, whilst the working expenses had very considerably decreased, and they were declaring what was equivalent to a 10 per cent. dividend on preference shares. He was not, however, to be understood as suggesting that there was a prospect of the payment of a dividend on the ordinary shares in the immediate future. They had to get rid of the nine months' arrear on the preference shares, and there might be considerable sums required for increased rolling-stock, repairs, and renewals. Besides, he was very strongly in favour of at once commencing the formation of a substantial cash and invested reserve. The prospects of the Company were much brighter than they had been. The principal sum due to Messrs. Dick, Kerr, and Co., after the payment provided for them in the present half-yearly account should have been made, was £2,228. 15s. The Company was authorised to raise £5,000 additional debentures and preference shares, none of which had yet been issued. If the shareholders or the general public would subscribe sufficient of it to pay off Dick, Kerr, and Co., matters would be made much easier for the Company, and the prospect of a dividend on the ordinary shares increased.

The report was adopted.

KALGOORLIE ELECTRIC POWER AND LIGHTING.

The fifth ordinary general meeting was held on Tuesday at Winchester House, Mr. Roger W. Wallace, K.C. (chairman of the Company), presiding. Particulars of the report were given in our last week's issue.

In moving the adoption of the report, the **Chairman** stated that there was now a fresh-water supply at Kalgoorlie, but that the evaporating and condensing plant which had been sent out for converting the salt water would be available in case of emergency. Defining the policy of the Company, he remarked that the Company had had offers to take power, but they had thought it better to wait and get more remunerative prices, and also not to take every offer that was made, because they had to consider whether it was desirable to take loads which they might not be able to supply on a sudden demand, such as the supply to hoists which would only be at work certain times of the day. What they wanted was a regular supply, and not a supply which would leave the power standing idle at other times. They did not want to get exorbitant prices, but to do a good, steady business, and when the mine-owners came to recognise this he had no doubt that their power would be taken up, and that the business would increase. He recommended the shareholders, however, not to count upon a continuance of the abnormal rate of advance made during the 12 months under review, during which the sale of power showed an increase of 95 per cent. over the previous year.

The report was adopted unanimously.

BOLCKOW, VAUGHAN, AND CO., LIMITED.

The annual report states that expenditure upon new collieries, new blast-furnace plant, electric installations, machinery, and extensions during the year totalled £463 239. Of this sum £326,717 was for outlay on the new collieries at Ferryhill and Leasingthorne and new blast-furnace plant at the Cleveland Ironworks. It is also proposed to appropriate £100,000 from the reserve fund and £36,522 from the year's profits. The profit from all sources available for distribution, after providing for depreciation, is £199,641, which, with the added balance of £45,990 brought forward, it is proposed to distribute as follows: in payment of the dividend on the preference shares and on 1,629,760 fully-paid shares of 5 per cent., being 1s. per share, of which 6d. interim dividend has been paid, and a dividend on 1,860,900 shares (12s. paid) at 5 per cent., being 7·2d. per share, of which 3·6d. has been paid. Payment of extensions of new plant, etc., requires £36,522, leaving £48,190 to be carried forward.

LONDON UNITED TRAMWAYS.

In their interim report the directors state that the traffic receipts for the half-year were £139,452, against £132,932 last year, an increase of £6,520, with an increase in expenses of but £779. During the past seven weeks the receipts were £53 863, an increase of £5,172. An interim dividend on the ordinary shares at the rate of 6 per cent. per annum is announced. The large additional capital upon which the dividends have to be earned includes heavy expenditure upon important improvements and widenings of roads and streets incident to the doubling of the Hampton Court line and the construction of the cross-town connecting line between Hammersmith and Uxbridge-road, all of which might probably have been deferred; but the directors have considered it good policy in the permanent interests of the shareholders to at once provide for the future development of traffic rather than delay the outlays which, with the rapid advance in the value of property along the routes, would have had to be made at no distant date at an enormously increased cost.

YORKSHIRE ELECTRIC POWER.

The report for the half-year ended June 30 last intimates that the erection of the power station at Thornhill has made rapid progress. Current will be ready for supply to consumers this year, and contracts for this purpose are being negotiated. An agreement has been sealed with the Urban District Council of Mirfield for the supply of electrical energy in bulk. Under this agreement large power users in this district will receive a supply direct from the company, and economy in the cost of mains will thus be secured. Bills have been successfully opposed in this session of Parliament, promoted by various local authorities seeking powers to supply electricity outside their own areas. The directors trust that the definite lines laid down by the Parliamentary Committee on this matter will tend to hinder such attempts to encroach on the Company's area in the future. The accounts have now been closed, and a balance of £224 has been repaid to the Company.

LIENS REGISTERED.

Telephone Company of Egypt, Limited.—A trust deed, dated July 27, 1904, to secure £60,000 debenture stock, has been registered. Property charged: the company's undertaking and property, present and future, except uncalled capital (as a floating security). Trustees: Sir Auckland Colvin, Earl Soham Lodge, Framlingham; and G. F. Braithwaite, Kendal, Westmoreland.

Urban Electric Supply Company, Limited.—A trust deed, dated July 28, 1904, and a disposition of even date, to secure £200,000 first mortgage debenture stock, have been registered. Property charged (by trust deed): Electric lighting and tramway undertakings, certain freehold and leasehold hereditaments and the company's undertaking and property, present and future, including uncalled capital. (By disposition): Freehold property at Hawick. Trustees: Merchants' Trust, Limited, 63, Cornhill, E.C.

Electromobile Company, Limited.—A mortgage, dated Aug. 10, 1904, to secure £3,500 and further advances up to £10,000 has been registered. Property charged—15 per cent. of any moneys payable to the company under contracts for sale of automobiles or for garage, supply of electricity, or other services (not including moneys payable exclusively for tyre maintenance). Holders: North of England Trustee Debenture and Assets Corporation, Limited, 45, Spring-gardens, Manchester.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Swansea.—The Corporation invite tenders for two negative tramway boosters. Tenders by noon on Sept. 7. See advertisement.

Lemberg.—The Government Railways require tenders for accumulator battery at the central station at the railway station. Tenders by Sept. 4.

Mexico.—The Federal District Railway Company of Mexico require tenders for the electrification of six tramway lines in the town. Applications are to be made direct.

Bucharest.—The Roumanian Government Railways require tenders for supply and erection of electricity plant and for installation for lighting several workshops by 27th inst.

Pangbourne.—Tenders are required for lighting the village during the coming winter, for the Pangbourne Parish Council. Particulars may be obtained of Mr. C. West, jun., clerk.

The Hague (Holland).—The Council of the Hague require tenders for the supply of from 8,000 to 9,000 tons of steel rails, including appurtenances, for electric tramways. Tenders by Sept. 22.

Madrid.—Tenders are required by the Post and Telegraph Department for 70 tons of 4mm. galvanised iron wire, about £16 per ton, and 70 tons of 2mm. bronze wire, about £94 per ton, by Sept. 3.

Madrid.—Tenders are required by the Post and Telegraph Department for 9,000m. telegraph cable of 7 rubber-insulated wires, 2,000m. ditto of 28 paper-insulated wires, and 11,000m. cable of 7 steel wires by Sept. 6.

Hove (Sussex).—Tenders are invited for the supply, delivery, and laying, in the parish of Aldrington, of low-tension vulcanised-bitumen, dialite, or "leadless" paper cables, conduits, boxes, meters, etc. Tenders by Aug. 30. See advertisement.

Buenos Ayres.—The Municipality (Intendencia Municipal Section Obras Publicas) require tenders for the construction of an electric tramway from the Plaza de Mayo in the town to the suburbs of Ortuzar, Devoto, and General Urquiza. Tenders by Sept. 13.

London, S.E.—Tenders are invited for electric light installation at the Royal Arsenal Co-operative Society's, Limited, new branch stores, Plumstead Common-road, Plumstead, S.E. Tenders by 12 noon on Aug. 27 to Mr. Frank Bethel, 22, Queen Anne's-place, Bush Hill-park, Enfield, N.

London, S.W.—The London County Council invite tenders for the manufacture, delivery, and erection of three electric car traversers at certain of the Council's tramway depôts in the South of London. Specification, etc., may be obtained at the County Hall, Spring-gardens, S.W. Tenders by 10 a.m. on Oct. 4.

Greenwich.—The London County Council invite tenders for the manufacture, delivery, and erection at the tramways electricity gene-

Digitized by Google

rating station at Greenwich of the following plant: two 24in. centrifugal pumps and motors, one 3in. centrifugal pump and motor, two 8in. by 8in. three-throw air-pumps and motors, one 3in. artesian well pump, fixed and rotary strainers, etc. Specifications, etc., may be obtained at the County Hall, Spring-gardens, S.W. Tenders by 10 a.m. on Oct. 4.

Manchester.—The Directors of the Manchester Dock and Warehouse Extension Company, Limited, invite tenders for the wiring (for power and light) and electric lighting of five transit sheds (now in course of erection) on the southerly side of dock No. 9, in the county borough of Salford. Specification, etc., can be obtained at the office of Mr. W. H. Hunter, chief engineer to the Manchester Ship Canal Company, 41, Spring-gardens, Manchester. Tenders to Mr. F. A. Eyre, secretary, Manchester Ship Canal Company, 41, Spring-gardens, Manchester, by 10 a.m. on Aug. 30.

La Rochelle (France).—The Chamber of Commerce will shortly issue tenders for a crane with a lifting power for 30 tons. The beam, or the part which projects over the water or vessel alongside, should be long enough to unload from a point about 26ft. 6in. from the edge of the quay. The height of the distal end above the quay should be 15m. (49·21ft.); the vertical distance between the edge of the quay and that part of the crane directly over it, 8m. (26·4ft.). A locomobile is preferred, but should the conditions be unfavourable for installing such a machine, then a fixed crane would be adopted.

Australian Commonwealth.—Tenders will be received at the office of the Deputy Postmaster-General, Hobart (Tasmania), until noon on Sept. 30, 1904, for the supply and delivery at the General Post Office, Hobart, of one multiple metallic branching switchboard. Specifications may be seen at, and tender forms and conditions obtained from, the General Post Offices at Hobart, Melbourne, Sydney, Adelaide, Brisbane, and Perth. Tenders should be endorsed "Tender for Switchboard," and addressed to the Deputy Postmaster-General, Hobart. Tenders may be deposited in the tender-box at the General Post Office, Hobart, or, if sent by post, must be prepaid and registered. Tenderers must state the name of the country in which the switchboard will be manufactured.

RESULTS OF TENDERS.

Madras.—The Secretary of State for India has ordered one 15-b.h.p. Diesel engine for the Public Works Department, Madras.

Dewsbury.—The Corporation have accepted the tender of Messrs. J. and J. Horsfield, Vulcan Ironworks, Vulcan-road, Dewsbury, for supply and delivery of one Lancashire boiler at their electricity works.

Newcastle-upon-Tyne.—The Guardians have accepted the tender of Messrs. Woods, Slacke, and Co., Corporation-street, Blackburn, at £353, for installation of the electric light in the hospital block at the workhouse.

Brighton.—The Town Council have accepted the offer of the British Westinghouse Electric and Manufacturing Company to supply and fix the circulating water pipes required for the west side of the engine-room at the Southwick power station for £550.

Acton.—The Howard Conduit Company, Limited, Trafford Park, Manchester, have secured the order for all the troughing required in connection with the Acton scheme, which our readers will remember was recently secured by the St. Helens Cable Company, Limited.

Johannesburg.—The Municipal Council have awarded Messrs. W. T. Glover and Co., Limited, Trafford Park, Manchester, the contract in connection with electric light and power cables for the Johannesburg Municipality, amounting to considerably over £100,000.

Beverley.—The Visiting Committee have received the following tenders for internal electric fire-alarm communications:

A. Dickinson, Leeds	£263	7	6
Siemens Bros. and Co., Limited, Hull	250	0	0
Private Wire and Telephone Installation Company, Limited, London	220	0	0
King and Co., Limited, Hull	220	0	0
R. Ernest and Co., London	209	16	0
Blaker Bros., Middlesbrough	205	0	0
E. M. Parsons, Hull	190	10	0
W. G. Padget, Hull	190	0	0
W. L. Harrison, Hull	167	18	0
G. Dixon and Sons, Leeds	166	18	6
Cox-Walkers, Darlington (accepted)	133	0	0

BUSINESS NOTES.

LIGHTING AND GENERAL.

Beeston.—The Council propose to introduce electric lighting.

Grimsby.—It is proposed to expend £3,000 for distributing mains.

Leek.—Sanction has been obtained to a loan of £1,800 for electric supply purposes.

Rand Central Electric Works, Limited.—The gross revenue for July was £8,850, against £6,200 last year.

Sale of Plant.—Particulars of sales of dynamos, condensers, motors, Cyclone electric fans, etc., appear in another column.

St. Pancras.—The profits from the electricity department last year amounted to £7,220 being allocated for the relief of the rates.

Buxton.—The Urban District Council will advertise for a pupil at the electricity works, as Mr. Perrin's term expires at the end of the year.

Leeds University.—The next session for civil, mechanical, electrical, and mining engineering will begin on Oct. 4. Particulars in another column.

Christchurch (N.Z.).—The cathedral will shortly be supplied with power for the organ and heating the building by electricity from the city destructor.

Wireless Telegraphy Act, 1904.—A notice by the Postmaster-General with regard to the establishment of wireless telegraph stations appears in another column.

Watford.—The number of consumers connected to date is 350. A report and correspondence on the subject of pumping by electricity is to be printed and circulated.

Linlithgow.—A provisional order is to be obtained by the County Council, prior to a loan of £3,500 for the electric lighting of the village of Broxburn and Uphall.

Caerphilly.—The Urban District Council have appointed a committee to carry out the electric lighting scheme and to appoint an engineer. The cost of the scheme is estimated at £5,500.

British Insulated and Helsby Cables.—The directors have declared an interim dividend at the rate of 8 per cent. per annum on the ordinary shares for the half-year ended June 30 last.

Brighton.—The railway company are being asked to allow the Corporation to carry overhead cables on the side of the line to enable outside districts to purchase electricity from the Corporation.

Pitlochry.—In connection with the proposed introduction of electric light, a public requisition has been promoted asking for consent to utilise the water of the River Tummel to generate the current.

Personal.—Mr. J. Clifton Robinson, managing director of the London United Tramways, Limited, has been placed by the Lord-Lieutenant of Middlesex on the Commission of the Peace for the county of Middlesex.

Oldham.—The Town Council have decided to apply for sanction to borrow £48,000, partly for extra expenditure on buildings and plant in connection with the Greenhill and Rhodes Bank electricity stations, and partly for new mains.

Dundee.—An application by the National Telephone Company, Limited, for permission to extend their underground telephone cables in the outlying districts of the city has been remitted to a sub-committee for consideration and report.

Sunderland.—The total estimated expenditure of the Corporation electricity department for the half-year ending March 31. 1905, is £13 370. 12s 11d. The total revenue is estimated at £27,694. 16s. 2d., leaving an estimated gross profit of £14,324.

Stock Exchange.—Application has been made to the Stock Exchange Committee to appoint a special settling day in North Wales Power and Traction Company's 34,100 shares of £5 each, £4 paid, Nos. 1 to 34,000 and 37,401 to 37,500.

Victoria Technical School.—Messrs. Dick, Kerr, and Co., of Preston, have forwarded £500 for the purpose of completing the equipment of the electrical laboratory at the Victoria Technical School. The trustees of the late Mr. J. B. Booth had given £2,500 towards the same object.

Madrid.—The Ministry of Agriculture, Industry, Commerce, and Public Works has been authorised to acquire, without the formalities of calling for tenders, four lights of the fourth order in connection with the buoying and lighting of the estuary of Vigo at a cost of 38,500 pesetas (or about £1,100) placed *in situ*.

Rotterdam.—A new central station is about to be erected on the Schiehaven. An idea of the requirements may be obtained from the specifications for the foundations, etc., tenders for which are called for Aug. 30, and which may be obtained for one florin from Mme. veuve P. van Waesberge und fils, éditeurs, 73, Hout tuin, à Rotterdam.

Kingston.—The total expenditure on electric lighting, as shown by the electric light capital account, to March 31, 1904, is £86,468. A sum of £3,684 was expended during the year. The total receipts (amount raised by loans) remain the same as last year—viz., £76,226—and £10,242 represents the balance due to treasurer and to labour account.

Buckley.—At the last Urban District Council meeting it was suggested that as time went on the Council would be able to introduce electric lighting. They had got their own ground, near the Council chambers, upon which to put what plant would be required for supplying their own electric light. The present contract with the gas company will expire in about two years' time.

Alfreton Ironworks.—On Tuesday the new electrical works which have been erected for Messrs. Jas. Oakes and Co. at the Alfreton Ironworks, were formally opened in the presence of about 40 invited guests. It is proposed by the new works to substitute electric power for steam power. In the evening the firm entertained the members of their staff and a number of others to dinner at Greenhill Hotel, Riddings.

Dunedin (N.Z.).—The *New Zealand Mining and Engineering Journal* says it is anticipated that when the Lee Stream hydraulic works are completed there will be a considerable amount of surplus power to dispose of, but before the Dunedin City Council can supply either power or lighting for the city it will be necessary to obtain an order from the Governor-in-Council under the Electric Lines Act, 1884. The Tramways Committee of the City Council is now taking steps to obtain the necessary order.

Halifax.—The new set of engines that has been on order for some time for the electricity works is now being erected. It is a duplicate set of the one started at the beginning of the year. The engines are being erected by Messrs. Pollitt and Wigzell, of Sowerby Bridge, and the generator by the Electric Construction Company, of Wolverhampton. The cost of the scheme, with foundations, etc., will be not far short of £10,000. The set of engines started in January is now able to take

Digitized by Google

the whole of the tramway load on ordinary days, and with the assistance of the new set the works will be equipped for some years to come.

Gosport.—When the Provincial Tramways Company undertook the supply of electric traction the lighting of the district by electricity was also placed in their power, and the company agreed to pay the expenses of obtaining the order, which amounted to something like £500. The compulsory area includes certain districts and localities where electric lighting would not be required, but it is very large, and it is doubtful whether the company will undertake the supply unless the area is restricted. However, the order has been obtained by the Council, and it expires in December next, and notices of intention to apply for an order have already been served on the District Council by the Empire Electric Light and Power Company, Limited, and by G. Vaughan Fowler.

Revised Board of Trade Rules.—The Board of Trade have issued drafts of revised regulations and conditions for securing the safety of the public and for ensuring a proper and sufficient supply of electrical energy. We are informed that the experience which has been gained since 1896 has, in the opinion of the Board, rendered a revision of these regulations desirable, and drafts are classified as follows: (1) L.A.P.—local authority undertaking in the provinces; (2) C.P.—company undertaking in the provinces; (3) C.L.—company undertaking in London; (4) L.A.L.—local authority undertaking in London. The various codes differ according to circumstances in regard to the notices, etc., specified in the regulations as to supply, and in the codes relating to London the regulations as to overhead wires are omitted.

Derbyshire and Nottinghamshire Electric Power Co.—The company have taken central offices in Nottingham, and have appointed a preliminary staff. A preliminary station has been erected at Ilkeston, which has been at work since June of last year, and is satisfactorily supplying the whole of the power for the Corporation of Ilkeston tramways, and for the town lighting, and other customers are being arranged with and connected to the mains. An agreement with the Corporation of Newark has been entered into, and a station is to be established there to satisfy the demands of the Corporation and the customers in their area. An agreement is being concluded with the Nottinghamshire and Derbyshire Tramways Company for the power supply to some 40 miles of electric tramways in the company's area.

Newcastle.—In a report which has just been adopted the lamp inspector, Mr. George Lamb, points out that 180 electric arc lamps would be required to light certain thoroughfares in the city, and the total cost, at £12. 10s. per lamp, would amount to £2,250 per annum. This sum would include electric energy, ordinary maintenance charges, interest and redemption of capital expenditure. The total payment in respect to the existing 200 electric lamps was £3,100 per annum, and if the Tramways Committee reduced the price from £15 10s. to £12. 10s. per lamp per annum, there would be a reduction of £600 a year, making an annual charge of £2,500 for the 200 lamps. The cost of the additional 180 lamps at £2. 10s per lamp would be £2,250 per year, giving a combined total of £4,750 per annum for electric lighting.

Telegraph Clerks.—At Wednesday's meeting of the London members of the Postal Telegraph Clerks' Association in the Memorial Hall, Farringdon-street, the following resolution was passed: "That this representative meeting of the telegraph staffs of the whole Metropolis expresses its indignation that the Postmaster-General, having appointed a committee of his own choosing to enquire into Post Office wages; having invited the staff to prepare and tender evidence, which they did at great trouble and cost; having made statements in the House of Commons and elsewhere calculated to induce the belief in the minds of the staffs and the public that the findings of the committee would be adopted, now, for no good reason, has rejected their report. This meeting, therefore, calls upon the Postmaster-General to adopt immediately the whole of the recommendations of the committee on Post Office wages, in order to ameliorate the urgent and proved inadequacy of pay among the classes whose wages were investigated."

Tiverton.—An enquiry has been held into an application to borrow £13,000 for electric light purposes. The scheme was explained by the designers, Mr. J. Siddalls and Mr. J. S. Enright, the latter representing the contractors, F. Suter and Co. The annual receipts were estimated at £2,162, expenditure at £1,538, net profit £623. The Mercantile Association opposed on the following grounds: The rates were 6s. 8d., as compared with 4s. 11d. throughout England. The prosperity of Tiverton depended upon its being a cheap residential centre. The population had decreased 500 since 1891; there were many vacant houses, and rents had gone down considerably. Of 244 tradesmen canvassed, 160 said "no" to borrowing the money and 11 "yes," while 151 said "no" to taking in the light and 18 said "yes" The Mercantile Association regarded the light as unsuitable for a decreasing agricultural town like Tiverton. Mr. Siddalls, for the Corporation, said that 37 of the largest consumers had agreed to take in the light.

Carlisle.—The Postmaster-General, in his annual report, states that the proposals set forth in the report of last year with regard to the underground cable from London to the North have been carried into effect; the line of pipes is now completed as far as Carlisle; further north a section 19 miles in length has been laid across the Beattock incline; and a spur line of two pipes has been laid from Manchester to Leeds. A temporary cable has been provided over 25 miles of this latter section, the permanent cable has been carried northwards for a long distance on the main route, and provision has been made this year for carrying it as far as Carlisle. The laying of pipes as far as Glasgow is also contemplated. In order that the various sections of the underground system may be more readily available in case of damage to overhead lines, it has been decided to modify the scheme outlined in the Postmaster-General's report of July 29, 1902, and to carry the line direct to Glasgow, extending it thence to Edinburgh, instead of laying branches from Lanark to Glasgow and Edinburgh. This arrangement will also afford additional means of direct communication between Edinburgh and Glasgow, and the means of communication between Dundee and Aberdeen will be reinforced by the underground wires as far as Larbert.

Inquest.—The evidence at the inquest on the body of Christopher Walter Saunders, 21, a labourer in the employ of the Metropolitan Electric Supply Company, who was, while following his occupation, killed by an electric shock, showed that Saunders and other labourers were engaged last Friday in removing old electric cables and substituting new cables in Manchester-square, Marylebone. Saunders and Hennessy, another labourer, were together in a manhole, where a cast-iron pipe had to be cut to admit of the insertion of a new joint-box, and they were cautioned by the foreman to be careful as the pipe enclosed a "live main." For the purposes of this particular work, with which Saunders was said to be "familiar," he used a chisel, a hammer, and a "bursting wedge." The cable was insulated. Hennessy said that Saunders first made a small hole in the pipe with his chisel and then inserted the "bursting wedge" with his hammer. He struck the wedge twice with his hammer, and at the second stroke ejaculated "Oh!" and fell against the witness, rebounded, and dropped on the pipe. He was immediately removed, but found to be dead. Dr. W. F. Spurgin ascribed death to syncope consequent on an electric shock. Mr. James W. Drew, superintendent of mains to the company, stated that since this occurrence it has been decided to include hole-boring and wedge-inserting in the category of "dangerous operations," and instructions had been issued that the men engaged in this work must wear rubber gloves. The jury, in returning a verdict of "Accidental death," directed the company's attention to the circumstances of the case with a view to their adopting every practical means to prevent similar mishaps in the future.

Kent Electric Power Company.—The completion of the purchase of the undertaking of the Chatham, Rochester, and District Electric Lighting Company as a going concern by the Kent Electric Power Company is fixed for July 1 next. In the meantime the electric lighting company will carry on the undertaking; and pending the erection of a central station the electric lighting company are making arrangements for affording a temporary supply of current to customers who may require it. The company have also entered into an agreement with the Chatham and District Light Railways Company for the purchase of the whole of the plant in the existing power-house at Chatham. A part of the purchase consideration has already been paid, and the purchase is to be completed on July 1 next. From that date the company will operate the plant of the existing power-house and supply energy therefrom pending the completion of the central station. It has been found necessary to abandon the schedule site for a power station at Chatham; and in order to get the necessary coal conveyed direct from the steamers, instead of transhipping into barges, the company has, after considerable difficulty, acquired from the Ecclesiastical Commissioners on a 999 years' lease a site of eight acres for the erection of a central station at Frindsbury, with berthing facilities for steamers of large tonnage alongside. The preliminary installation at this station will consist of about 6,000 h.p., and the directors congratulate themselves on the fact that the whole of the work and plant will be of British construction. Negotiations are also pending for the erection of another power station at Northfleet. Many contracts have been entered into by the company for the construction of the central station and the supply of a very large amount of electrical energy to manufacturers and others in the locality, the supply to be afforded in rather more than a year's time on the completion of the central station.

London Gazette.—The partnership between James Lochhead and John Priestley Rhodes, carrying on business as electric merchants at Vance's-buildings, Cloth Hall-street, Huddersfield, Yorks, under the style of the Huddersfield Electric Company, has been dissolved by mutual consent. A receiving order has been made in the estate of James William Hunter, 8, Norwood-road, Leeds, and Albert Clapham, 289, Kirkstall-road, Leeds, electrical engineers and motorcar dealers, and trading together in co-partnership as the Yorkshire Motorcar and Electrical Engineering Company at 101, Kirkstall-road. The first meeting will be held at 11 a.m. on Aug. 31, 1904. A general meeting of the members of the Single-Wire Multiple Telephone Signal Company, Limited, will be held at 69, Electra House, Finsbury-pavement, London, E.C., on Sept. 26 at 2 p.m., to receive the liquidator's report showing how the winding-up of the company has been conducted and its property disposed of. The following notice appears in the matter of the Edison and Swan United Electric Light Company Limited, and Reduced: The capital of the Edison and Swan United Electric Light Company, Limited, and Reduced, henceforth is £941,090, divided into 150 000 "A" shares of £5 each, 26,436 "B" shares of £5 each, and 23,564 "B" shares of £2. 10s. each, instead of the original capital of £1 000,000 divided into 150,000 "A" shares of £5 each, and 50,000 "B" shares of £5 each. At the time of the registration of this minute, 116,400 of the said "A" shares and 23,564 of the said "B" shares have been issued, and the following amounts are to be deemed to have been paid up on the same respectively: upon each of the 99,261 "A" shares numbered in the register of the company from 1 to 99,261 inclusive the sum of £3, upon each of the 17,139 "A" shares numbered 01 to 017,139 in the said register the whole amount thereof. Upon each of the said 23,564 "B" shares numbered in the said register from B 1 to B 23,564 inclusive the sum of £2. 10s. The remainder of the capital is unissued.

Carnoustie.—At the last meeting the town clerk read correspondence with Mr. George Balfour, who proposed to promote an electrical power company in Dundee. It was stated that Mr. Balfour intended to apply for a provisional order to acquire the necessary

Digitized by Google

powers for erecting buildings and constructing conduits. The draft agreement further bore out that the company should have the use of the streets so far as necessary for its purposes, while binding themselves not to supply electrical energy for lighting purposes within the city, except with the consent of the Corporation. The company also bound themselves not to supply any of the customers presently connected with the Corporation supply, and if the Corporation desired any further special exemptions they would consider it. The promoters sought the right to supply electric energy for motors for all classes of machinery in textile and other factories. They made a proviso that they would not lay cables in the streets of the central area of the city, and that their works would be subject to the approval of the Corporation, and it was stated that they would erect no overhead wires. In a subsequent communication Mr. Balfour pointed out that the Corporation, in the event of themselves going in for a power supply, would require to open the streets, so that no objection could be taken to his proposal on that score. He proposed to give Dundee the commercial advantages of cheap electrical power enjoyed by other centres of industry. Mr. Balfour expressed his willingness, in event of an agreement being come to, that the Council themselves should open and reinstate the streets for the company, charging a just and reasonable cost. This explanation, he considered, removed any objectionable features from the proposed agreement. The scheme would serve a limited number of consumers, chiefly millowners and manufacturers and it appeared to him that a speculative concern of this kind was one which the municipality would not be anxious to take up. He did not think the Council would be agreeable to erecting a power station involving an outlay of a quarter of a million pounds sterling for the benefit of, say, not more than 100 or 150 consumers. There were, in Mr. Balfour's opinion, a great many other reasons why the proposed scheme should be dealt with as a private undertaking. Mr. Balfour, in the course of his correspondence, sought an interview with the Town Council after his return from America in October.

TRACTION.

Pudsey.—A provisional order for an electric tramway scheme is to be applied for by the Town Council.

Southend.—The work of constructing an electric tramway by the coastline towards Shoeburyness is to be proceeded with at once.

Leicester.—During July the trams carried 2,032,849 passengers, being an increase of 1,085,031 over the same month of last year.

Swindon.—The *plébiscite* on the question of Sunday running has resulted in an overwhelming vote in favour of having cars on that day.

Rochdale.—The Board of Trade last week approved the new circular tramway route, which is about two miles in extent, and it was immediately opened for traffic.

Keighley.—It is reported that the completion of the scheme of Corporation tramways to Stockbridge has been postponed for a time, and that it may be necessary to apply for an extension of time.

Wellington (N.Z.).—The City Council propose to float a special loan of £77,000, at 4½ per cent. with a currency of 25 years, for the extension of the electric tramway to Island Bay, Ohiro, and Kilbirnie.

Bury, Rochdale, etc., Tramways.—A meeting of the joint authorities was held last week in reference to the allocation of the purchase money to be paid to the company, but Mr. More's report on this subject had not arrived.

Bury.—Mr. A. W. Bradley, the borough engineer, states in his annual report that the employment of direct labour in the construction of the tramways has resulted in a saving to the town. The remainder of the tramways are to be laid by the same method.

Aberdeen.—The Corporation have confirmed the Tramway Committee's recommendation that the fares should remain as at present, with the exception of the section from Market-street to the Woodside terminus, on which the fare is to be reduced from 2d. to 1½d.

Metropolitan Electric Tramways, Limited.—The number of passengers carried over the recently electrified route of the Metropolitan Electric Tramways, Limited, for the Bank Holiday week was 353,789 as compared with 198,061 for the corresponding period last year.

Light Railways.—The Board of Trade has confirmed the orders made by the Light Railway Commissioners authorising the construction of the Cheltenham and District Light Railway (Extension No. 3) and amending the Maidstone and Faversham Junction Light Railway Order, 1901.

Light Railways in Belgium.—There are now working in Belgium 1,300 miles of light railways, and about 430 more miles are in course of construction. The State capital sunk in them is a little over six millions sterling. The profit on the lines actually working amounted in 1903 to over £150,000.

Sarria-Barcelona.—The Sarria-Barcelona Railway Company have applied for a concession for an electric railway from Sarria to the district of Vallvidrera. There will be a statutory interval of one month before the application is decided upon, in order to give other concerns an opportunity of offering better terms.

Pontypridd.—At a special committee of the Pontypridd Electricity and Tramways Committee last Friday evening a long discussion ensued as to the advisability or otherwise of working the tramways as a municipal undertaking, or taking the advice of an expert with a view—if considered desirable—to lease the lines to a company. The question has been before the Council frequently. Finally, it was resolved to obtain expert information.

Birmingham.—Between 11 and 12 o'clock on Tuesday night a serious tramway accident occurred in Birmingham, resulting in 24 persons being more or less seriously injured. A portion of Coventry-road on the Small Heath route is at present up in preparation for the installation of the electric tramway system, and a steam car was proceeding over this section at a slow pace, when it over-ran the points and fell into an excavation from 2ft. to 3ft. deep, completely overturning. There were 47 passengers on board, 19 of whom were on the top, and a large number of these were pitched off, and many seriously injured. The car was completely smashed, and the top had to be sawn away.

Tramwaymen and "Live" Wires.—An interesting feature in connection with the Manchester tramwaymen's sports at Bellevue on Wednesday was a competition for dealing with "live" wires. Four emergency crews (each four strong) competed, and they were judged entirely upon time. Two poles were erected, with a wire connecting them, and for the purpose of the competition the wire was supposed to be "live," and was broken just before the signal being given to each crew. On the call being given the horses were fastened up and driven to the supposed breakdown. The tower of the wagon was raised, and the "live" wire picked up, joined, and made ready for the resumption of traffic. The competition proved very exciting, and on the timing Hyde-road No. 2 crew (with 3 minutes 29⅗ seconds) beat Queen's-road No. 2 crew (3 minutes 44⅗ seconds). Queen's-road No. 1 crew was third and Hyde-road No. 1 crew fourth.

Heywood.—At a meeting of the Town Council a long discussion took place on the tramway deadlock. The speakers vigorously denied that Heywood was responsible for the failure of the negotiations for the reconstruction of the tramways and the running of a through service between Bury and Rochdale through Heywood. It was pointed out that Bury and Rochdale had offered certain terms which were accepted by Heywood. Then Bury sought to amend these terms, and when Heywood would not accept the amended suggestion, Bury declared the negotiations at an end. The action of Bury in opposing Heywood's application to the Board of Trade for an extension of the time for the construction of the tramways in Heywood—an application necessitated by the failure of the negotiations—was declared to be an attempt to force Heywood to accept Bury's terms; and satisfaction was expressed that the Board of Trade had granted an extension of six months, with power to apply again if necessary. All the speakers agreed in expressing willingness to meet the neighbouring corporations and to discuss terms in a friendly manner.

Middlesex Light Railways.—The first section (Tottenham to Wood Green) of light railways constructed by the Middlesex County Council was opened on Saturday last by Sir Francis Cory-Wright, chairman of the Tramways and Light Railways Committee. The importance of the event attaches rather to the development of the scheme in progress than what has been actually carried out to date, since the section completed represents but a very small portion of the undertaking which the Council have embarked upon. When finished the present scheme will provide tramway facilities over about 50 miles of the main roads of the county. An interesting and, we think, a wise feature of the Council's policy in the matter is that the new lines have been leased to the Metropolitan Electric Tramways Company, Limited, by whom they will be worked until 1930. The cost of constructing the track is borne by the Council, and the electrical equipment and rolling-stock are provided by the company. A sum of 4½ per cent. on the Council's expenditure will be paid by the company as rent; out of the gross receipts the company will take 4½ per cent. on its capital expenditure and net revenue; and the net profits will be divided, the Council taking 45 per cent. and the company 55 per cent. The current is supplied from the Brimsdown power station. Now the company in question, it is well known, have an extensive tramways system of their own in course of development, and the advantage attained by the above arrangement of having the two systems under one management will tend to the best results in working, especially as physical connections are provided between the respective systems, which are therefore distinct only as regards ownership. We hope to give fuller details in a subsequent issue.

Stockport.—The annual tramway accounts to March 31 show that the traffic revenue for the year was £19,073. 2s., as against £14,679. 16s. 7d. in the previous year, while the total working expenses amounted to £12,209. 9s. 1d., as compared with £10,014 7s. 2d. Thus while the gross profit in the previous year was £4,666. 15s. 2d., last year it was £7,069. 9s. 4d. There were, however, over four miles more of lines to draw revenue from, the length of the system amounting now to some 10½ miles. The gross profit was applied as follows: extinction of last year's debit balance, £563. 3s. 7d.; interest on mortgage debt, etc., £3,834. 6s. 1d.; redemption of debt, £1,333. 18s. 4d.; rent of tramways, £1,174. 17s. 6d.; suspense account, preliminary expenses, £96. 0s. 7d.; net profit, carried forward, £67. 3s. 3d. The total cost per car per mile, including electrical energy, traffic expenses, general expenses, repairs, and renewals, was 4·830d., as against 5·322d. in the previous year. The car mileage was 606,476, and during the year 3,170 854 passengers were carried. The units of electrical energy totalled 790,892, giving the number per mile 1·30. The percentage of working expenses to receipts was 64; the average traffic revenue per car per mile, 7·54d.; the average traffic revenue per mile of single track, £971; the average total revenue per car mile, 7·62d.; average car miles per day per car, 109·45; average working expenses per car mile excluding power cost, 3·152d.; average working expenses per car mile including power cost, 4·831d.; average fare paid per passenger, 1·4d.; average number of passengers per car mile, 5; average journeys per head of the population per annum, 28; average number of cars in daily service, 15·18. There are altogether 30 cars. The gross capital expenditure on the system so far is £140,276. No provision has been made for depreciation, the Tramways Committee contending that this is unnecessary at such an early stage. In the report of the Corporation's auditor, however, there is a recommendation that some provision should be made in the future.

Digitized by Google

Perth.—At a meeting of the Tramway Reconstruction Committee last week a large number of offers were received for the electrification of the tramway system. Tenders were invited for this work as a sort of safeguarding measure, in so far that should the petrol car prove a failure the Town Council, having these offers before them, would be in a position to immediately launch the scheme for the electrification of the system. A committee was appointed to consider the offers.

Huddersfield.—Considerable success is attending the arrangement for the conveyance of parcels on the Corporation electric tramways. The parcels are carried at charges varying from 1d. to 3d., the goods being handed over to applicants at various fixed stopping places, or "left until called for" with tradesmen on the various routes. A feature is made of dinner parcels, which are carried daily at a charge of 3d. a week. Last year over £700 was earned by the parcel department. The Board of Trade have certified the Longwood section as fit for traffic. The employés protest against the proposed annual medical inspection.

Belfast.—The Corporation have signed a request to the Board of Trade to appoint an arbitrator in connection with the acquisition of the company's undertaking. It is understood that the Tramways Committee have been in communication with Mr. Andrew Nance, manager of the Belfast Street Tramways Company, in reference to a proposal that he should be appointed manager of the Corporation tramways. Mr. Nance has intimated his willingness to accept the position on certain terms as to salary and other matters, and the Tramways Committee will communicate with other corporations owning tramways as to their practice in this respect.

Ashton.—At a meeting of the Tramways Committee a member, commenting upon the arbitration proceedings in connection with the Manchester Carriage Company, characterised the result as disastrous to Ashton. It will be remembered that the Corporation had to take over the horses of the company. The employés are aggrieved at the split-turn system introduced by the manager, and the committee, while approving the manager's action, have indicated that they will meet the men's wishes as far as possible. An arrangement has been entered into with the Manchester Corporation relative to the payment to be made by that authority for special cars running into the district.

Bewdley.—At a special meeting of the Town Council on Wednesday the application to the Board of Trade by the Kidderminster and District Electric Lighting and Traction Company for an extension for two years of the power conferred under a light railways order to make a tramway from Kidderminster to Bewdley was considered. The Mayor proposed a resolution, which was unanimously adopted, that the Board of Trade be informed that, as better travelling facilities between Kidderminster and Bewdley were most urgently needed, it would be unfair to the public that the time for making the tramway should be extended for two years, but if the tramway company were prepared to give an undertaking to the satisfaction of the Board of Trade that the tramway would be constructed within the proposed prolonged period of the extension, the Council would raise no objection to the application.

Swansea.—In reference to certain remarks made in the *Swansea Post* relative to the progress of the tramway extensions, Mr. W. Foley, engineer to the contractors, Messrs. Dick, Kerr, and Co., replies: "There is no real or serious delay. The contract is well ahead of schedule time, and what little stoppages have taken place have been due to matters relating to the gas company and water people. In Oxford-street, Port Tennant, and Wind-street our trenches have been cut right over the mains, and negotiations had to be entered into. At Eversley-road, Sketty, we were waiting for a loop; and at Sketty-road the Corporation's delay in road widening was responsible for a stoppage. Not a single minute was lost on account of the non-delivery of rails, etc., all of which are on the spot. I don't say if there had not been three holidays, the King's visit, etc., we should not have finished; but granted all goes well and the gas company and water department do their duty, we shall be completed by October certain."

London County Council.—Enquiries are being made by the residents of Nine Elms, Battersea, and Wandsworth as to when the tramways in those districts will be electrified. An official of the Council recently stated that the Battersea Park-road line would be converted "at no distance of time." Interviewed on the subject by a *Daily Chronicle* representative, Mr. John Burns, M.P., stated: "Work has already been commenced on the new authorised line from Tooting-broadway to Wandsworth. It will proceed by way of Defoe-road, Garratt-lane, and South-street, and, crossing Wandsworth High-street by the new road, will join the existing lines to Westminster and the Borough, which will, of course, be electrified as a continuation of the scheme. The widenings in York-road and Nine Elms-lane are practically complete, and when once the work starts from Wandsworth it should be completed in three or four months, for we are learning to do the thing much quicker now. On the Lavender-hill route the widenings are not yet completed, but you may have electric trams there much sooner than you think."

Rhodesia Railways.—The company's report shows that for the year ending March 31 last the revenue amounted to £573,286 against £526,560 for the previous year, the expenditure represented £434,542 against £322,774, and the profit £138,744 against £203,786, the percentage of expenditure to receipts being 75·8 per cent. against 61·3 per cent. During the 12 months ending March 31 last 212 miles of the Bulawayo-Victoria Falls line, the Gwelo-Selukwe branch (24 miles long), and 74 miles of the Gwanda branch were opened for traffic, the total length of line in operation at that date being 1,208 miles. Considerable reductions in fares have been made. The whole line from Bulawayo to the Victoria Falls was opened for traffic on June 20. The Zambesi is to be spanned by a railway bridge in the immediate neighbourhood of the falls. The Vryburg-Mafeking section has been relaid with 60lb. rails in place of the old 45lb. rails. New working arrangements have been entered into with the Mashonaland Company and the Cape Government, by which the former undertake the working of the whole of the company's system except the section from Vryburg to Bulawayo, which remains in the hands of the Cape Government.

Mashonaland Railway Co.—From the report of this company, covering the years ending Sept. 30, 1901, 1902, and 1903, it appears that for 1900-1 the revenue from the conveyance of general goods (the main source of income) was £139,689, construction goods £90,570, and from passengers £18,393; for 1901-2 the figures were £175,575, £80,454, and £79,997; and for 1902-3 the figures show £209 049, £79 997, and £18 049. The percentage of expenditure to gross receipts for the second of these periods showed some reduction over that for the first, and for the third period there was a substantial reduction over the second. For the nine months ending June 30 last the proportion is less favourable than for the year 1902-3, owing to the decrease in the volume of traffic consequent upon the depression in trade; but with a revival of trade in Rhodesia the directors look forward with some confidence to a change in this respect. Through bookings have now been arranged between the company and all the railway systems in South Africa, and an agreement has also been concluded with the German East Africa shipping line.

Ashton and Stalybridge.—The negotiations between the Ashton Corporation and the Stalybridge, etc., Joint Board for through running would appear to have been brought to an abrupt conclusion by the action of the Joint Board in refusing to entertain Ashton's latest offer, of which we gave particulars in our issue of the 12th inst. The Joint Board practically adhere to the terms previously indicated by them—that each authority shall retain the fares taken in their respective districts. They reject the proposal for arbitration. The Ashton Corporation decided to reply that they had nothing further to suggest. At a future meeting the Corporation will consider the advisability of constructing the Old-street and Scotland-street length of line, and running their own cars to the county bridge, Whitelands. An informal conference subsequently took place between the chairman of the Ashton Tramway Committee and the chairman of the Joint Board, but nothing definite was settled. "If," said the former to a local reporter, "Stalybridge would recognise the principle of halfpenny fares between Ashton Old-square and Cockbrook, and Cockbrook and Stalybridge Town Hall, and a penny through, the whole thing would be settled, and each authority would get the benefit of its own local receipts, and what it was entitled to."

Halifax.—In order to utilise their tramways to a greater extent for goods traffic, the suggestion has been made that in their next parliamentary Bill the Corporation should seek for powers to enter the navigation yards both at Halifax and Sowerby Bridge, and thus put the tramways in direct communication with the canal. It is claimed that a considerable saving, even in the transference of their own supplies, could be effected by the Corporation by such an arrangement, while, in addition, the direct communication with the canal thus secured would also help in the general development of goods traffic on the tramways. It is understood that the matter is receiving the attention of the sub-committee appointed to report on the tramway requirements to be provided for in the Corporation's next parliamentary Bill. The doubling of a number of the existing lines and the extension of the tram service to Elland by way of Salterhebble Hill and West Vale are also matters which will be reported on. The Tramways Committee have decided to recommend an extension from Sowerby Bridge to Style Bank at an estimated cost of £4,200. A sub-committee has been appointed to consider the staffing of the tramways department. Some members consider that it would be an advantage to split up the undertaking into departments, with a responsible head to each, under the general manager.

Newcastle.—At the invitation of the Tramways Committee a large number of members of the City Council last week made a survey of a part of the tramway system, especially some of the latest acquisitions and extensions. These included a new 3,000-h.p. engine at the power station, new car sheds at Wingrove, and an important addition of lines from Byker to Welbeck-road and Church-street, Walker. The party included, besides the chairman, the vice-chairman (Mr. J. D. Rodgers), the mayor (Alderman Andersen), Mr. Geo. Renwick, M.P., Councillor Renwick, of Cardiff (the junior member's brother), Sir Wm. H. Stephenson, Aldermen Sutton, Sanderson, Morton, Councillors Weidner, Harkus, Beattie, Flowers, Coates, Fitzgerald, Cail, Archibald, W. J. Sanderson, Farquharson, C. C. Elliott, Criddle, Mason, Robson, Murray, Hutchinson, H. Forster, Whitburn, and Meyne; Mr. J. Fewster, Mr. Gjemre, Mr. J. Ellis, Mr. W. Ellis, Mr. Le Rossignol (general manager of the tramways), Mr. J. C. Couper (traffic superintendent), Mr. Edge (city engineer), and other officials. After an extensive inspection there were refreshments and speeches, in the course of which Alderman Ellis (chairman of the Tramways Committee) stated that the committee were striving to the best of their ability to manage the trams so that they might reflect the greatest credit on the Council and the people. As yet the system was new, but before the end of the year it would be put upon such a basis that the people of Newcastle would be satisfied with the result.

Bradford.—When the annual accounts, of which we gave particulars in our issue of the 12th inst., were presented to the Tramways Committee, a request was made for supplementary information. In response, the city treasurer has prepared a series of returns showing the exact financial position of the Bradford tramways undertaking on March 31 last. The accounts are classed under different headings, and in substance they go to amplify the general statement made by Alderman Godwin a short time ago in introducing the annual municipal "budget." During the past year no less a sum of £40,000 was spent upon repairs and renewals, which, together with the sum of £2,917 set aside for depreciation, represents a percentage of 5·79 on the total working capital of the undertaking. The committee drew upon the depreciation and renewals account, which is practically a reserve for contingencies, to the extent of £5,000 for relaying a length of line in

Digitized by Google

Thornton-road, and for covering certain expenditure on the Eccleshill and the Stanningley tramways. The sum now standing to the credit of that fund is £23,056. Great reductions were made in the fares on the lines taken over from the companies. The obligations attaching to the cost of reconstructing and equipping the lines were a first charge upon revenue, but the shareholders of the old companies had also to be recompensed, and the surrender value of the companies' leases has since been paid in instalments. In 1903 the sum of £9,000 was paid out of the net profit of close on £20 000 which was then made, and, similarly, this year the balance of £10,482 due to the old companies is to be paid out of the total net profit of £13,399. The amount set aside for interest and sinking fund amounted to £46,105, which was some £10,000 more than in the previous year. This was attributable to the rapid development of the system, the bulk of the capital expenditure on which was debited in the accounts for the year ended March last.

Derby.—The contractors for the Derby tramways (Messrs. J. G. White and Co.) entertained the members of the Tramways Committee and their ladies to luncheon at the Royal Hotel on Monday afternoon. The guests also included several of the principal Corporation officials. The chair was occupied by Mr. Connett, of Messrs. White and Co., with Mr. Balfour, of the same firm, in the vice-chair. After the usual loyal toasts, the Chairman proposed "The Derby Corporation Tramways Committee," and referred to the delay which had arisen in the completion of the work. On behalf of the contractors, he disclaimed responsibility, and said it was due to several unforeseen circumstances, not the least important of which was the determination of the Corporation to have English rails after having first agreed to the use of rails made in Belgium. Alderman F. Duesbury, J.P., chairman of the Tramways Committee, responded, and expressed the opinion that the contractors had made "a very good job." In this connection he paid a tribute to the watchfulness of the borough surveyor (Mr. John Ward), who, he said, had been very vigilant in looking after the interests of the ratepayers. "The Mayor and Corporation" was proposed by the vice-chairman, and Councillor J. W. Gandy, J.P., gave "The Health of the Contractors." During the proceedings the contractors presented handsome silver flower vases to the Mayoress and Mrs. Duesbury. These articles bore suitable inscriptions commemorative of the inauguration of the electric tram system in Derby. The Normanton-road section is nearly finished, while good progress has been made along the Burton-road. St. Peter's-street continues to be closed to vehicular traffic. Messrs. White and Co.'s employés have been working night and day during the present week, and confidently expect to complete their labours by the end of August. Arrangements are being made for the Board of Trade to make their official inspection in the first week in September, and, subject to the Government certificate being obtained, there will be an immediate extension of the present system.

Portsmouth.—The Mayor has negotiated for the purchase of certain premises, the removal of which will allow the awkward "S" curve to be abolished, and a practically straight line to be laid down The Tramway Committee have approved of the Mayor's action, and recommend that the purchase be effected. The annual report of Mr. W. R. Spaven, the general manager for the 12 months ended March 31 last, shows that the year's working has resulted in a total revenue of £94,174. 0s. 9d. Deducting from this amount the tolls paid to the Portsdown and Horndean Light Railway, there was a net revenue of £92,916. 18s. 6d., an increase over the previous year of £8,966. 16s. 6d. The working expenses for the year amounted to £43,426. 14s. 4d., which, together with instalments of principal and interest transferred, makes a total expenditure of £76,888. 7s., and gives a credit balance of £16,028 11s. 6d. By placing this balance to the amount already transferred, there is an accumulated reserve fund for the tramways of £22,993. 10s. 8d. The rents, rates and taxes have increased from £2,665. 11s. 5d. to £5,506. 9s. 9d., due to the assessment of the undertaking having been increased, and there is also an increase in the principal and interest charges. The average length of the penny section is now 1½ miles, as against 1⅛ miles previously. The changes thus made account for the falling-off in the average receipts per car mile from 12·37d. to 12·19d. Over 1,800,000 passengers have been carried in excess of the number conveyed during the previous year, and estimating the population of Portsmouth at 198,000, the tramways have carried the whole number of the population no less than 92 times this year. The mileage for the year shows an increase of over 199,000 miles compared with that of the preceding year. The length of the route is about 14½ miles, and there are 28 miles of double track, only half a mile being single track. The maximum gradient is 1 in 17; the sharpest curve is 35ft radius; carrying capacity per car is 56 passengers; car miles run per annum, 1,828,193; average per day, 5,008; passengers carried per annum, 18,204,426; per day, 49,875; passengers carried per car mile, 9·95; traffic receipts, £87,266. 8s. 3d.; average per day, £239. 1s. 9d.; average traffic receipts per car mile, 11·45d.; average per passenger, 1·14d.; gross receipts (less £1,257. 2s. 3d. tolls paid to light railway), £92,916. 18s. 6d.; average net receipts per day, £254. 11s. 1d.; average per car mile, 12·19d.; average per passenger, 1·22d.; percentage of working expenses to total receipts, ·46. Incorporated in Mr. Spaven's report is the report of the resident engineer, Mr. V. G. Leroni, on the power station, overhead line, cables, permanent way, and rolling-stock. A very satisfactory feature of the year's working is the reduction of the generating cost per unit by ·16d., bringing the cost now to the low figure of ·55d.

PROVISIONAL PATENTS, 1904.

AUGUST 15.

17674. Improvements in and relating to telephones. Samuel James Port, Cobden-buildings, Corporation-street, Birmingham.

17675. An automatic protection for third or live rail used on electric railways. Garnett Senior, 9, Olive-street, Sunderland.

17705. Improvements in vaporisers. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

17717. Improvements in electrical switches. Charles Julius Klein, 40, Chancery-lane, London.

AUGUST 16.

17733. Improved suspension fitting for electric motors. George Davis, 15, Victoria-street, London.

17738. Improvements in switchboards. Isaac Hardy Parsons, Faraday Works, Leicester.

17741. Alternating-current power-transmitting apparatus. Wallace Fairweather, 65, Chancery-lane, London. (Arnold Magnetic Clutch Company, United States.) (Complete specification.)

17752. Improved magneto-electric generator. Rooke Ainsworth and P. R. Jackson and Co., Limited, 70, Deansgate, Manchester.

17764. Improved means of regulating electric circuits. Harry Hill, Lynton, Dartnell-park, Byfleet, Surrey.

17784. Improvements in or relating to electrolytic cells. Edgar Arthur Ashcroft, 111, Hatton-garden, London.

17792. Improvements in and relating to the manufacture of incandescent electric lamps. Jean Michel Canello, 7, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Sept. 12, 1903, being date of application in France. (Complete specification.)

17805. Improvements in or relating to telephone and other conducting cords. Thomas Henry Martin Harvey, 322, High Holborn, London.

17808. Improvements in electrical measuring instruments. Evershed and Vignoles, Limited, and Sydney Evershed, 1, Queen Victoria-street, London.

17809. Improvements in electric controllers. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

17811. Improvements in automatic brakes. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

17812. Improvements in electric fuses. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

17813. Improvements in systems of electric motor control. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

17823. Improvements in or relating to telemeters. Giovanni Aragno, 111, Hatton-garden, London.

AUGUST 17.

17837. Improvements in terminals for secondary and primary batteries. Jasper Myers Richardson, 427A, Strand, London.

17841. Improvements in electric motors. Walter John Hawkins, 178, High-street, Tooting, London.

17862. Improvements in and relating to electrical conductors, specially applicable to overhead conductors for electrical tramways. Ernest Marsh Ginders, 34, Castle-street, Liverpool.

AUGUST 18.

17939. Improvements in electric trolleys. Jean Lauvernier, 23, Mittelstrasse, Berlin. (Complete specification.)

17975. Improvements in the control of electrically-propelled vehicles. John Smith Raworth, 46, Lincoln's-inn-fields, London.

17978. Improvements in or relating to suspending or supporting electric motors or differential gear or both on motor road vehicles or tramway vehicles. George Beloe Ellis, 70, Chancery-lane, London. (La Société A. Vedrine et Cie., France.)

17980. Improvements in the method of and apparatus for making pipes and conduits. George Edward Heyl-Dia, 6, Lord-street, Liverpool.

AUGUST 19.

17997. Improvements in electrical switches. Frederick Francis MacDonald, Bank-buildings, George-street, Sheffield.

18020. Improvements in electrical driving mechanism for machinery in general. Joseph Richard Hill, 7, Staple-inn, London.

18021. Improvements in insulating electric conductors. Isidore Kitsee, 18, Fulham-place, Paddington, London. (Complete specification.)

18034. Improvements in or relating to electric automobile vehicles. George Beloe Ellis, 70, Chancery-lane, London. (La Société A. Vedrine et Cie., France.)

18042. Improvements in processes of oxidation and reduction effected in an electrolytic bath. Oliver Imray, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Farbwerke vormals Meister, Lucius, und Brüning, Germany.)

Digitized by Google

AUGUST 20.

18655. Improvements in or relating to trolley heads of electric tramcars. Holberry Mensforth, 2, Market-street, Bradford.

18669. Improvements in electro-mechanical apparatus for automatically operating the rail and electrical conductor points on electric tramways and railways from the tram or train. George Dudley Aspinall Parr, The University, Leeds.

18687. Improvements in the transmission and distribution of electric power. Jacob Krüyswijk, 77, Chancery-lane, London.

18695. Improvements relating to telephone switchboard cords and like flexible electric conductors. William John Burton and Charles Lincoln Burlingham, 11, Southampton-buildings, Chancery-lane, London. (Complete specification.)

18698. Improvements in and connected with wireless telegraphy and apparatus for carrying out the same. George Cecil Dymond, 6, Lord-street, Liverpool. (Gesellschaft für drahtlose Telegraphie m. b. H., Germany.) (Complete specification.)

18101. A new or improved means of converting alternating current for use with continuous-current electrical measuring instruments and the like. Walter Charles Head, 62, Stoke Newington-road, London.

18105. Improvements relating to the transformation of repulsion motors when running at speed into rotating field asynchronous motors. Marius Latour, 7, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Aug. 27, 1903, being date of application in France.) (Complete specification.)

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Sept. 8, 1904.

1903.

17601. Systems of electric lighting. Leitner and Lucas.

18010. Galvanic batteries. Fiedler and Gerard.

18076. Electric traction. Sayer.

18186. Telphers. Siemens Bros. and Co., Limited, and Clift.

18250. Thermal cut-outs. Carolan. (General Electric Company.)

18256. Time-limit controllers for circuit breakers. Carolan. (General Electric Company.)

20101. Construction of armatures for dynames and motors. Maclean.

20606. Multipolar dynamo-electric machines. Holmes.

21805. Alternating-current electric motors. British Thomson-Houston Company, Limited, and Meyer.

21654. Rheostats. Hobart and Punga.

21663. Electrical switches. Porter.

21140. Engine telegraphs or signals on board ships. Isdale.

21320. Apparatus for electric signalling. Brodin and Schepeler.

21972. Dynamo-electric machinery. Mawdsley.

22097. Trolley or like current collectors for electric traction. Upham.

22190. Alternating-current induction motors. Hunt and Sandycroft Foundry Company, Limited.

22507. Electrically-controlled hoists. Steven.

22906. Machines for covering electric conductors or the like with insulating material. Carolan. (General Electric Company.)

23910. Bearings for electric meters and other measuring instruments. Carolan. (General Electric Company.)

23546. Telephone mouthpieces or receivers. Cruickshank.

23767. Galvanic batteries. Halsey Electric Generator Company, Limited. (Halsey Electric Generator Company.)

24025. Printing telegraph receivers. White.

25657. Lightning arresters or devices for preventing overcharging in electric conductors. Zapf.

26165. Electrical elevators. Smith.

27133. Protective device applied to X-ray or radiant-matter tubes. Harnack.

28623. Joint-box for electrical conductors. Martin.

1904.

43049. Electric switches. General Contracts Company, Limited, Cook, and Chipperfield.

7823. Telephone transmitters. Fairweather. (American Electric Telephone Company.)

14350. Electrically-operated signalling and braking devices for railway trains. Krause.

14553. Burglar and other electric alarms. Getto.

15512. Lid for accumulator and other acid-containing boxes or tanks. Clark and Hart Accumulator Company, Limited.

15561. Indicators for electric oscillations. Thompson. (Gesellschaft für drahtlose Telegraphie m. b. H.)

15567. Electric or telephonic transmission. Carbonelle.

15657. Regulating mechanism for arc lamps. Upton, Elliott, and Pratt.

NOTES.

Personal.—We understand that Messrs. Browett, Lindley, and Co., Limited, have again secured the services of Mr. F. C. Gibbons, who has now been appointed sole managing director of the firm. It will be remembered that Mr. Gibbons was for many years associated with Messrs. Browett, Lindley, and Co., Limited, and that he left them to join Messrs. Howden and Co. His return to Messrs. Browett, Lindley, and Co., Limited, should have beneficial results as a sign that in business old friends are best, and we wish the firm every success under his management.

Rheinfelden.—Negotiations are proceeding between the German and Swiss Governments with reference to the utilisation of the Rhine at Laufenburg for generating power in connection with the extension of the Rheinfelden works, to which we referred in our issue of April 29. It will be remembered that in the course of this enlargement use is being made of an island in the Rhine, and as at this point the river forms the boundary between the two countries, the works will be situated partly in each. This will be the first international convention for the regulation of electric power.

Iron and Steel Institute.—We have received a copy of the revised programme in connection with the American itinerary. On arrival in the capital one party will enter upon a tour to Cleveland, extending from Oct. 27 to Nov. 9, in the course of which they will visit several points of interest, including the Schenectady works of the General Electric Power Company. A second party will proceed to the St. Louis Exhibition. An earlier function has been fixed for the 13th inst., when the institute will give a dinner to a party of the Liège Association of Engineers at the Hotel Cecil, the time fixed being 7.30. Tickets (price £1. 1s., including wine) may now be had from the secretary, 28, Victoria-street, S.W.

New Publications.—"The Diseases of Electrical Machinery," by E. Schulz (London: E. and F. N. Spon). This little volume provides a concise handbook on a subject that has received limited attention in electrical publications. In a brief preface, humorous and felicitous, it has the recommendation of Dr. S. P. Thompson.—"Relations between the Effects of Stresses Slowly Applied and of Stresses Suddenly Applied in the Cases of Iron and Steel Comparative Tests with Notched and Plain Bars," by M. Pierre Breuil (London: E. and F. N. Spon). The secretary of the Iron and Steel Institute has forwarded us a copy of this publication, which is issued as a supplement to vol. lxv. of the institute's *Journal*, and describes the author's researches into this subject, which gained him the gold medal for 1904. The work, we may add, is admirably illustrated.

The Ether-Pressure Theory.—A paper was contributed by Mr. J. Macfarlane Gray to Section A at the Cambridge meeting of the British Association, in which he examined the important experiments of Dr. Grindley in the light of the ether-pressure theory, the basis of which is indicated by the following: Newton regarded the pressure of the ether as very great and sufficient, by its slope, to account for terrestrial and stellar gravitation. Ether-pressure cannot be selective; if it acts upon stars it must also press upon every atom of matter and be the most important of all natural forces, and the fundamental factor in every physical phenomenon. Neothermodynamics therefore begin with ether-pressure as in equilibrium with every other pressure, whether of solids, liquids, or gases. The play space of every contributory molecule of gas, as its amplitude of vibration was acquired, from absolute zero temperature—even if in an envelope of constant volume—must have been obtained by driving back the ether, and, just as external work is $p\,v$, so this internal work is also $p\,v$. The translation energy of gas is $1\frac{1}{2}$ times its $p\,v$; or, the constitutional energy of a gas exclusive of external work is $2\frac{1}{2}\,pv$. Including the external $p\,v$, the total energy from absolute zero is $3\frac{1}{2}\,p\,v$, and the ratio is 1·4. By this reasoning the same ratio must hold good for all gases.

An "Electric Thinking Machine."—A correspondent writing from Baden, Switzerland, sends us a facsimile of a letter received by him, the text of which we reproduce, and asks if any of our numerous readers can solve the enigma. We think we can do so, and that the writer is a gentleman who has called at this office making much the same statements as those contained in the letter. He is an electrical engineer who has been responsible for outdoor work on mains, and is now afflicted with an idea that his thoughts and actions are influenced by some malicious person from a distance. When he called to see us he stated that he had been informed by this means (?) that he had been appointed chief electrician on board the King's yacht. So implicit is his faith in such delusions that he actually went to join the yacht, which was then at Southampton. The letter, which is sent from South Wales, England, and dated Aug. 23, 1904, reads as follows: "Sirs,—Please is there at your Estab. Electric Thinking Machine if so. which Gentleman has ordered a Machine to speak me. & give thoughts to me. Wrong explanations speaking & thoughts given to me. *Very Bad*, 2 persons Welsh. follow my thoughts Day & Night, *Scandal. Search your Machine & Stop persons at once* I dont know where to Apply. *Machine open not Locked.* Some person did pass by me or somehow for Electric Machine when I did not know."

Chamber of Commerce.—The London Chamber of Commerce has for some time past been in communication with the representatives of the Commonwealth of Australia, the Government of India, and the Canadian Government relative to the levying of duty upon price-lists and catalogues sent to Australasia, India, and Canada. As a result of the representations made, the practices of the several customs authorities have been defined, previous to which considerable ambiguity existed as to the levying of duty or otherwise. The Government of India, in a recent communication, have stated that "as they consider it desirable to afford all possible facilities for the development of trade, they have issued instructions that all trade catalogues and circulars imported into India by packet, book, or parcel post shall in future be admitted free of duty.' In reference to Canada, the High Commissioner has informed the chamber that *bonâ fide* trade catalogues and price-lists of goods for wholesale not exceeding three to one person, are admitted into Canada without payment of customs duties. As regards Australasia, the manufacturers and Australasian sections of the chamber have also communicated with the Colonial Chambers of Commerce, who have unanimously supported the representations of the London Chamber in favour of the free admission of trade catalogues into Australasia. It is to be regretted, however, that up to the present the representations have not been favourably considered by the Commonwealth Government, it being officially stated that the primary object of the duty was not for the purpose of revenue, but for the encouragement of local printing, and that, therefore, the Commonwealth Government has no present intention of altering the law in this connection. Further efforts are being made with the object of

Digitized by Google

obtaining a reconsideration of the matter by the Commonwealth Government, and it is suggested that the free importation of trade circulars and price-lists will largely assist in promoting the trade of the Empire.

International Meteorological Committee.—At the meeting of the International Committee on Sept. 11, 1903, a proposal to constitute a sub-committee to combine and discuss meteorological observations from the point of view of their relations with solar physics was adopted, and the following gentlemen were elected thereto: M. A. Angot, Bureau Central Metéorologique, Paris; Prof. S. P. Langley, Smithsonion Institute, Washington; Sir Norman Lockyer, Solar Physics Observatory, South Kensington; Prof. J. M. Pernter, Hohe Warte, Vienna; and Mr. W. N. Shaw, Meteorological Office, London. It was left to the sub-committee to supplement the number of its members and to constitute its bureau, and the sub-committee nominated seventeen scientists belonging to various parts of the globe for membership. A meeting during the Cambridge session of the British Association was decided upon, the subjects enumerated in the programme comprising the selection of the meteorological and magnetic elements which should be collated for the purpose of comparison with solar observations, and the form in which the observations might be presented with the greatest advantage for the purposes of the comparison; the specification of solar observations which should be collected for the purpose of the comparison, and the preparation of a list of observatories which should be asked to furnish such observations; the means that should be adopted to facilitate the collection of observations arranged upon a uniform plan; and the consideration of additional methods of observation bearing upon the subjects which are not yet in general use in solor or meteorological observatories, such as the observations of solar radiation.

Fireproof Insulated Wire.—A description is given in the *Street Railway Journal* (New York) of a fireproof insulated wire devised by the Teter-Heany Developing Company, of York, Pa. Our contemporary remarks that in the general trend of modern engineering toward fireproofing, electrical insulators, especially for wires, have been to a great extent neglected, not so much because of lack of effort in this direction as on account of the difficulties that surround the subject. Asbestos is an excellent though not the only material for this purpose, but its thickness, frailness, unevenness, and cost has precluded its general use. It is to supply this gap that the Teter-Heany Developing Company, of York, Pa., has devised its fireproof insulated wire. By an ingenious device, asbestos, in its fibrous form, is applied directly to the wire, and then is treated with a special cement that on pressure and heat yields a firm, hard, even, thin insulation, that is said to be efficient in every respect. It is stated that the insulation will not crack, peel off, or break under bending or twisting, and that it will withstand temperatures above red heat without being destroyed. The advantages claimed over ordinary asbestos covering are that the total thickness of insulation is but ·011in., and ·009in. may be obtained if desired. This is the same as double cotton-covered insulation, and in its use old forms can be employed without alteration. While asbestos insulation is ordinarily very uneven, this insulation varies on the average about ·003in. Asbestos, while it will not burn, will crumble under heat, and so become useless for insulating purposes. This insulation protects the asbestos, so that it will stand much higher temperatures without crumbling. A coil in possession of Mr. Heany has been heated red-hot several hundred times, for hours on some occasions, yet the coil retains its insulation unimpaired. Temperatures of this degree are rarely met with in practice, and no effect whatever is observed at temperatures that usually cause coils to burn out. This means that coils wound with this wire, armatures, fields, arc lamp and transformer coils, etc., are practically indestructible. As our contemporary remarks, there is a wide field for this wire for use in motor and generator coils, especially for electric apparatus subjected to heavy overloads, and, in fact, wherever a high degree of heat is met with and must be resisted. The insulation has been thoroughly tested, both in the laboratory and in practice, with very satisfactory results.

Presentation to Huddersfield's Tramway Manager.—Mr. H. W. Thomas, who for the past five years has held the position of general manager of the Huddersfield Corporation tramways, was the central figure in a gratifying ceremony at Monday's meeting of the Tramways Committee. The Chairman (Councillor T. H. Moore), in moving a resolution recording the committee's appreciation of the zeal, ability, and success with which Mr. Thomas had discharged his duties, and congratulating him upon his appointment to an important office at Durban, testified from personal experience to the diligence and courtesy he had invariably shown. These sentiments were endorsed by the Vice-Chairman (Councillor Cartwright), who expressed the hope that Mr. Thomas would enjoy health and happiness in his new sphere, and the resolution was carried unanimously. The Mayor (Alderman R. H. Inman), in conveying the vote of thanks to Mr. Thomas, presented him with a piece of plate, bearing an appropriate inscription, and subscribed for by all the members of the committee. His Worship remarked that it afforded him great pleasure to convey these tokens of the high esteem in which Mr. Thomas was held by the committee. They were conscious that as the head of a large and important department like the tramways he had exercised his best efforts and energies, not only in making it a financial success, but also to give a maximum of comfort and convenience to those who used the trams. In conclusion, his Worship associated himself with the views of the chairman, and echoed the hope to which the vice-chairman had given expression. Mr. Thomas, in response, thanked the committee for their manifestations of appreciation, and wished prosperity to the tramway undertaking.

A 500,000-Volt Transformer.—One of the features of the Palace of Electricity at the St. Louis Exhibition is the 500,000-volt transformer exhibited by Mr. C. H. Thordarson, of Chicago, who has made a special study of high-tension apparatus. It is of the closed magnetic circuit type, with a capacity of 20 kw., and is operated from 110-volt 60-cycle mains. The primary and secondary coils are wound on a laminated core, the whole being immersed in oil. The weight of the iron in the magnetic circuit is 700lb., and the weight of copper is 45lb. in the primary and 60lb. in the secondary coils. The tank containing the oil is of wood, lined with metal. The two terminals of the secondary coil rise out of the oil to a height of 2ft. above the top of the tank. These terminals placed 32in. apart are surrounded by standards heavily insulated with paper boiled in paraffin. The wires emerge from glass insulators which cap the paper insulation. After leaving the insulated standards, the current passes through heavy choke coils and then to the terminals proper. As usually operated, a heavy glass plate is placed between the two points, and the discharges, leaping a maximum distance of 32in, around this plate, have a particular fascination for the spectators. The discharges between the two points are attended with a sharp crack when the arc is established. Frequent reports of lesser volume, due to the opening of shorter paths across the atmosphere, when the main arc in its fantastic writhings assumes such a shape that the resistance of a short cut

Digitized by Google

across the air is less than that of the long arc between the two points, continue as long as the arc is sustained. No detriment to the transformer results from these discharges, thus proving that the maximum voltage for transmission is governed by the insulation of the line and not by that of the transformer. For varying the voltage of the transformer a regulator is provided. This consists of a transformer with a ratio of 1 to 1, whose primary is connected to the Exposition mains. The secondary coil is movable, and by operating a regulating wheel can be moved out of the main path of the magnetic flux of the transformer and the voltage so reduced. We summarise the foregoing from the *Electrical World* of New York.

Energy of Water and Steam at High Temperatures.—This subject was dealt with by Prof. C. Dieterici in the paper which he contributed to Section B of the British Association at the Cambridge meeting. The author has devised a method for determining the specific heat of water at temperatures up to 300deg. C. The water is enclosed in quartz tubes, which are sufficiently strong to withstand the pressure of steam—namely, about 100 atmospheres at 300deg. C.—and the determinations are made with the aid of the ice calorimeter. The results obtained may be expressed by the formula $c_t = 1{\cdot}0160 - 0{\cdot}0_3 6057\ t + 0{\cdot}0_5 4302\ t^2$, in which the specific heat, c_t, is given as a function of the temperature. The formula holds between 50deg. and 300deg. C., but does not hold below 50deg. C., because at such low temperatures the point of maximum specific heat first observed by Rowland occurs. The observations made with water completely enclosed in a tube give the difference between the energy of the liquid water at t degrees C. and that of the water at 0deg. C. Since the heat of evaporation is known or calculable, this quantity, diminished by the external work, gives the energy difference between saturated steam and liquid water at t degrees C. Very careful observations have been published by Sir W. Ramsay and S. Young (*Phil. Trans.*, 1891) on the pressure of unsaturated steam between 140deg. and 270deg.; and since the relation between energy change and volume at constant temperature is given by the equation $\left(\frac{\delta\ U}{\delta\ v}\right)_\tau = \tau\ \left(\frac{\delta\ p}{\delta\ \tau}\right)_v - p$ of the mechanical theory of heat, the change of energy of superheated steam depends only on the pressure, and can be calculated from the author's present observations. It is, therefore, possible to calculate the energy isothermals, and to draw the isothermal lines for water. After applying the most accurate methods of calculation possible to the new observations, the author draws the following conclusions: At about 200deg. C. the specific heat of superheated steam at constant volume is 0 5, and is practically independent of the volume if the latter is much greater than the saturation volume. As, however, the volume diminishes to the volume of saturation, the specific heat increases to about 0·7. The specific heat at constant pressure, C_p, similarly varies from 0·6 to 0·8. Further, in the well-known equation of state of Van der Waals, $p + \pi = \frac{R\ T}{v - b}$, the cohesion pressure, π, cannot be taken as $\frac{a}{v^2}$, but is such a function of v and T that it has a considerable value for large volumes at low temperatures, and for small volumes at higher temperatures.

Universal Testing Machine.—The paper presented by Mr. J. H. Wicksteed, the president of the Institution of Mechanical Engineers, to Section G at the Cambridge meeting of the British Association had for its subject "A Universal Testing Machine of 300 Tons for Full-sized Structural Members." The machine will admit a column or strut 88ft. long, 3ft. 3in. square in cross-section. It will admit a beam 3ft. 3in. broad, 6ft. 6in. deep, and 20ft. between supports. It will shear a bar of mild steel 8in. by 2½in. It will break a steel wire rope 9in. in circumference. It makes autographic stress-strain diagrams in all these tests. The sensibility of the machine with a pull of 100 tons is 1 in 10,000. The purpose of the machine is not simply that of testing the strength of material itself, but it is for testing the strength of a full-sized member of any structure—that is, the strength which results from the disposition of the material in the sections and in the proportions of, for example, a strut, an eye-link, or a beam. The reason for employing a machine for the purpose of making tests instead of loading on full loads directly upon the specimen is, that for no reasonable cost could you possibly make experiments with heavy loads applied in bulk. Three hundred tons of accurate dead weights would themselves cost about £2,400; their application to the specimen would be so tedious that each experiment would cost as much in time and in labour as 100 experiments conducted in the machine to be described, where the full load is applied through hydraulic pressure and balanced by small accurate weights acting through levers and knife-edges. To minimise time and labour in making tests on various forms of structural members, this machine has been so designed as to be applied, without any change of apparatus, either to thrusting strains or pulling strains, and this is accomplished by making the straining frame in the form of a large trough, which is pushed forward by a hydraulic plunger, and which carries with it a straining head capable of being locked at any part of its length. This trough, hydraulic ram, and cylinder are completely surrounded by a balancing framework of tension rods and cross-heads, and this enables the straining cross-head to apply its force to one part of the balancing frame which surrounds it for compression tests, and to another part of the balancing frame for tension tests. Wherever the force may be applied to the balancing frame, it is delivered to the levers and poiseweights where it is measured. Besides the facility for bringing forces to bear either in compression or tension, it is requisite that no labour should be involved in arranging the machine to take in long or short pieces, and this is accomplished by mounting the straining head upon wheels, so that it can be quickly run to any part of the moving trough and locked there by bolts, which can be shot with the same facility as those in the door of a strong-room.

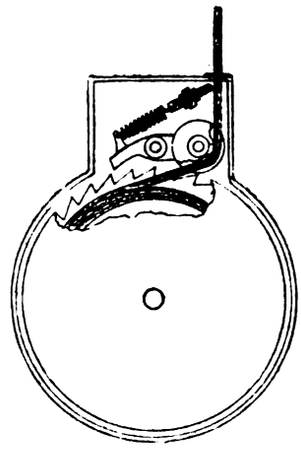
Harcourt Pentane Lamp.—"Some Investigations on the 10-c.p. Harcourt Pentane Lamp made at the National Physical Laboratory" was the title of the paper contributed by Mr. Clifford C. Paterson to Section G at the recent meeting of the British Association. This paper gave briefly the results of investigations carried out at the National Physical Laboratory in order to determine changes in the illuminating power of the 10-c.p. Harcourt lamp due to variation in (1) barometric pressure, (2) in the quantity of water vapour present in the air. When photometric comparisons are made between the pentane standard and a source of light unaffected by atmospheric conditions, as, for instance, an electric incandescent lamp, errors of the order of 5 per cent. may be introduced into candle-power measurements if corrections are not made for the hygrometric and barometric conditions existing at the time. In order to ascertain the amount of variation, photometric comparisons were made against two large-bulb Fleming-Ediswan electric standard incandescent lamps. The double comparison method only was employed, and the two electric lamps used to standardise a comparison incandescent lamp anew for each experiment, so that it was only necessary to burn the standards for five or ten minutes at a

Digitized by Google

time. It is found convenient to state humidity volumetrically, as the number of litres of water vapour to a cubic metre of pure dry air, at the barometric pressure existing at the time; so that if b = reading of barometer in millimetres, e = aqueous pressure, and e_1 = vapour tension of carbon dioxide present in the atmosphere, the litres of water vapour per cubic metre of pure air equal $\frac{e}{b-e-e_1} \times 1{,}000$. Upwards of 60 observations have been made on different days over a range of humidity varying from five to twenty litres per cubic metre, which are about the limits obtained under ordinary conditions in a well-ventilated photometer room; 80 per cent. of these, when corrected by means of the formula, fall within + or − ½ per cent. of 10 c.p. The barometric pressure in these observations has varied from 739mm. to 780mm. of mercury, so that, applying the method of least squares for these two variables, the following formula has been obtained for correcting the candle-power of the lamp to the standard atmospheric conditions of 760mm. of mercury and 10 litres of water vapour per cubic metre of pure dry air. Candle-power = $10 + 0\,066\,(10 - \epsilon) - 0{\cdot}0008\,(760 - b)$, where ϵ is the humidity as explained above and b the height of the barometer in millimetres. From this it will be seen that a variation of one litre per cubic metre in the moisture causes a variation in candle-power of about 0·7 per cent., and that 10mm. change in barometric pressure brings about an alteration of 0 8 per cent. in the illuminating power of the lamp. The standard humidity of 10 litres per 1,000 has been fixed upon as being the mean value for three years found at Kew Observatory. The figure is also borne out by observations made at the Meteorological Office.

The Penetrating Power of "N_1-Rays."—Prof Blondlot recently drew attention to a novel kind of N rays, diminishing, instead of augmenting, the phosphorescence of calcium sulphide. These rays, called by him "N_1-rays," are given off from a Nernst lamp simultaneously with the N-rays, and are also produced by stretching out a copper, silver, or platinum wire. In a paper recently presented to the French Academy of Sciences, Mr. Julian Meyer describes some experiments with these N_1-rays, produced by an extended glass or copper wire or by a closed glass tube, in the interior of which the pressure is diminished, an account of which is given in the *Scientific American*. The glass of the tube, on account of the strain resulting from the difference in pressure, was, in fact, found to be a powerful source of N_1-rays. The brilliancy of a screen covered with sulphide spots and introduced into a glass bulb resting on the plate of an air-pump would diminish when the machine was started, but would recover its initial value as the air was allowed to re-enter. If the sulphide screen be placed outside of the bulb, the phosphorescence would likewise diminish from the very first stroke of the piston. An incandescent lamp bulb, not traversed by any current, a hydrogen Geissler tube, a Crookes tube, were all found to be sources of N_1-rays without being actuated by a Ruhmkorff coil. While the N_1-rays from a Nernst lamp are arrested by an oxidised lead plate or by a sheet of moistened paper, those issuing from the sources named are gifted with a high penetrating power; in fact, the action of incandescent lamp bulbs on the screen is not appreciably diminished if between the bulb and the screen there be inserted a board 10cm. in thickness or a sheet of oxidised lead 1mm. in thickness and folded round itself so as to be traversed eight times, or else a glass vessel filled with pure water. Pasteboard, paraffin, aluminium, zinc, iron, copper, silver, gold, mercury, and the hand are also transparent to these radiations. The only opaque bodies found were platinum of a thickness of 1mm. and opalescent glass 3mm. in thickness. While examining the refraction of the rays by means of an aluminium lens, the author stated that this metal would store the rays in great amounts, giving them off again for more than 24 hours after it had been withdrawn from the source. A similar power, though of smaller intensity, was found in the case of ordinary glass; while lead, copper, and pure water did not show it. Salt water and a solution of sodium hyposulphite in water, on being submitted to the action of a source of N_1-rays, would become active themselves, acting as sources for a very long time. When the hand is held for some time at a small distance from a source of N_1-rays or touching the latter, the hand would diminish itself the phosphorescence of the screen, this property being kept for some minutes. N_1-rays as given off from the above sources are refracted by glass, copper, and aluminium prisms and diffracted by a grating. We notice, by the way, that the French Academy of Sciences has awarded the Le Compte prize of 10,000fr. to Mr. Blondlot for his researches into the N-rays.

New Trolley Catchers.—The accompanying illustration, taken from our contemporary, the *Street Railway Review*, shows a new trolley catcher for preventing the trolley pole from springing up when the trolley leaves the wire, quickly enough to avoid damage to the overhead apparatus, in connection with which application has been made for a patent in the United States by Mr. E. H. Amet.



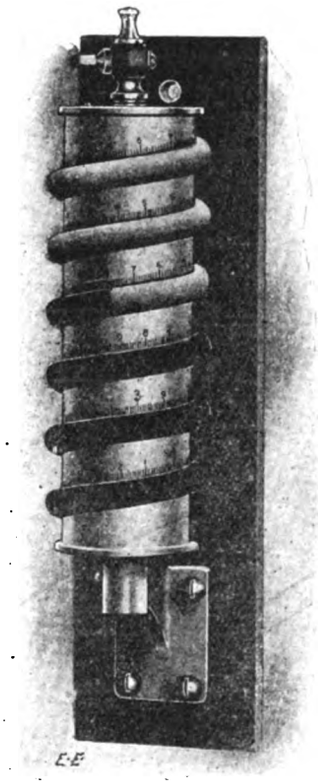
The appliance comprises an ordinary drum for taking up the slack of the cord, which drum acts like a self-rolling window-shade pole, keeping a slight tension on the cord at all times. The locking device is the main feature of this invention. The cord, it will be observed, passes over a small grooved idler, which revolves on a bearing mounted on one end of the pawl or dog, and the other end of the pawl is free to engage with the teeth of the ratchet on the winding drum. As long as the trolley wheel remains on the wire the cord passes smoothly back and forth from the winding drum, and the spring attached to the pawl prevents it from engaging the racket. When the trolley wheel leaves the wire, the sudden upward pull on the idler end of the pawl throws the free end of the pawl into the ratchet, and this locks the drum. It will be seen that it is not necessary that the drum should move at all to lock the catcher. The same journal gives a short account of the Shanahan trolley catcher and retriever, recently invented by Mr. T. B. Shanahan, of the Shanahan Trolley Speciality Company, which, it is stated, has emerged successfully from numerous tests, and invariably performs its work regardless of speed, rain, snow, or ice. It works entirely automatically, and the instant the trolley leaves the wire, from any cause whatever, it will pull it down from 2ft. to 6ft. as may be desired, and hold it there until released. Replacing the trolley and resetting the retriever are accomplished easily and quickly. The motive power of the retriever is a

Digitized by Google

large spring, and this can be adjusted to any tension desired, so as to correspond with the tension of the trolley pole. Two bases are furnished with each retriever, and these are attached to the ends of the car, and by the use of a small locking lever the device can be changed from one end of the car to the other very readily without the use of tools.

Wireless Telegraphy.—The developments of the last few months show that the ethergram has entered upon a new phase. How far the promises that have been held out for its extensive development will be realised it would be premature to say; but the system may fairly claim now to have obtained a distinct footing commercially and in other important spheres, while there are indications that considerable expansion is in prospect. Following on its partial adoption by the Eastern Telegraph Company, news comes from America that the De Forest wireless telegraph is working commercially between the St. Louis Exhibition and Springfield, Illinois, a distance of 105 miles. Other installations are in progress, notably between New York and Philadelphia, which are to be used for ordinary telegrams by day and Press work at night. The De Forest Company has also entered into a contract for the erection of 20 stations in Morocco, where the system will, at any rate, have the advantage of being immune from the wire-mutilating operations of the brigand; and the same company has been engaged to instal a service connecting the various islands of the Azores, which are not suited to cables, owing to the rocky condition of the ocean bed. In France the control of the system has lately been transferred to the Ministry of Commerce. The agreement recently entered into by the Canadian Government with the Marconi Company calls for the installation by July 1 next of seven stations, two of which have already been in communication with Allan Line steamers. In Italy, where the Government have taken up an encouraging attitude, the largest station in the world is to be installed at Pisa, and will be designed to establish communication with Great Britain, Holland, the Northern Continent of America, the Indian Ocean, and the Baltic. The belligerents in the Far East have employed the system with much success, and in last Saturday's *Times* there appeared a complete and highly interesting account, dated June 20, from the special correspondent of that journal, describing the achievements of the De Forest wireless telegraph in the interests of journalism, and the now historic action of the Russian authorities in closuring the enterprise. The *Times* correspondent expresses the opinion that this will prove to be the first and last instance of the system being used by a journal to report naval warfare, and predicts that in future it will be controlled during military and naval operations by international law as constituting a menace in the hands of unscrupulous users. The new Wireless Telegraphy Bill and the report of the Board appointed by the United States Government afford some confirmation of this view, and it is probable that political considerations will cause this field to be materially circumscribed, if not extinguished. Apart from this, the invention has played a unique part in journalism by the establishment of the "ocean daily." Another use is exemplified by the wireless telegrams for meteorological purposes inaugurated by the *Daily Telegraph*, pending Government action, and in this repect the promptitude of the United States in adopting a similar recommendation by the above-mentioned Board to that previously advanced by the English committee, is in marked contrast to the dilatoriness of the authorities in this country. These are some instances of the system *in esse*, and the advent of the thermo-galvanometer and other apparatus may appreciably facilitate progress. It has just been reported from Rome that a young student of the Lycée of Arpino has invented a device for neutralising attempts to intercept messages. A series of tests were conducted at the laboratory of the college, as a result of which an application has been made to the Government for a grant to pursue the experiments on a large scale.

A Draft Gauge.—The necessity of accurate determinations and the desirability of a strong, portable, direct-reading, ornamented, unbreakable draft gauge or monometer which can be mounted on a gauge board and read to $\frac{1}{100}$in., with a capacity of 6in. pressure or vacuum, led Mr. C. E. Sargent, of Chicago, to design the instrument shown in the accompanying diagram, some particulars of which are given in the *Electrical World* of New York. It consists of a nickel-plated brass cylinder, closed at both ends, encircled with a spiral groove in which is wound a transparent flexible celluloid tube, the bottom end of which is cemented in and communicates with the interior of the brass chamber. An extension of its lower head passes through the bracket, which supports the gauge,



yet allows it to be revolved at will, around its vertical axis. The whole device can be attached to a gauge board if desired. A small hose cock to which a rubber tube can be attached admits pressure through the top head of the cylinder. Distilled water, usually coloured, is put in the cylinder through this cock until the zero mark is reached on the scale. Pressure will cause the level of the liquid to ascend in the tube, and for every inch of vertical rise it will travel around the cylinder a distance of about 9in., which is divided into 100 equal parts. The angle of the tube is such that the plane of the meniscus is radial, making close reading possible. The cylinder can be rotated so that the level of the liquid comes on the front side. Rarefaction causes the liquid to descend, and by adjusting the cock any degree of steadiness of the level in the tube may be obtained. The upper end of the tube is closed with a screwed brass plug, and the inlet cock is shut when the gauge is carried about, maintaining the liquid in place without danger of spilling. As the tube is tough and elastic it is not liable to be broken. The whole device is 3in. in diameter by about 12in. long, and weighs about 3lb.

FLAME TEMPERATURES IN INTERNAL-COMBUSTION MOTORS.*

BY DUGALD CLERK, M.I.C.E.

Had we lived in an atmosphere of much greater density, it is probable that the internal-combustion motor would have developed on very different lines from those actually followed. Assuming an atmosphere of double the present density, say 30lb. pressure absolute per square inch instead of 15, for given flame temperatures the explosion pressures would have been double, and the non-compression engine of Lenoir would have been much more successful; perhaps, also, the schemes of the earlier English inventors, such as Brown (1826), to produce a gas-engine using vacuum and condenser like the steam-engine, would have been crowned with success. Had we lived in a very dense atmosphere, say of the order of 70 existing atmospheres, there can be little doubt the compression combustion motor would not have appeared at all, because it would not have been really needed. The explosion pressures to be dealt with would have been so great that the necessity would have arisen for reducing pressure instead of increasing it. This is very well shown by some most interesting explosion experiments recently made by Mr. J. Petavel, of Victoria University, with gas and air mixtures previously compressed over 70 atmospheres and then ignited. These mixtures produced pressures of the order of four to five tons per square inch.

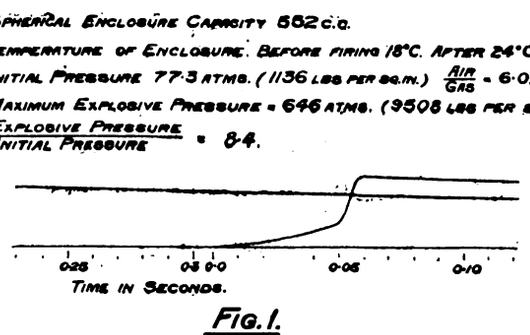

FIG. 1.

RISE OF PRESSURE.

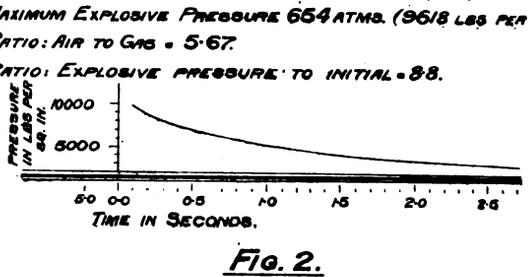

FIG. 2.

FALL OF PRESSURE.

Mr. Petavel's Experiments with High-Pressure Gaseous Explosions Coal Gas and Air.

Figs. 1 and 2 are prepared from photographic diagrams which Mr. Petavel has been good enough to send me. They show Mr. Petavel's rising and falling curves with explosive mixtures with about one volume of gas to six volumes of air. It is quite apparent that a gas-engine constructor existing in a world having an atmosphere 70 times as dense as our own would be dealing with explosion pressures of up to five tons per square inch at ordinary atmospheric pressure instead of the modest 100lb. per square inch, which is the limit of pressure obtained from ordinary gaseous explosions without compression at present. It is interesting to follow to some extent the effect of such changed conditions as these. It has long been assumed by gas-engine designers that the heat loss to the enclosing walls of an explosion chamber does not increase in proportion to the increase of pressure or density of the gaseous mixture before explosion. No accurate measurements, however, appear to have been made under rigidly determined conditions until some experiments, also by Mr. Petavel, upon the loss of heat to atmospheres of different densities from incandescent metallic wires kept at constant temperatures. Mr. Petavel finds (what gas-engine people long believed) that the loss of heat increases relatively slowly with increase of density. Roughly, his figures appear to prove that, with an atmosphere of 100 density, the loss to the walls increases only six times that of the loss at unit density. This, of course, means that, if a gas-engine could be operated in an atmosphere of double density using exactly the same temperatures, the heat loss would not by any means be doubled. With the same temperatures, therefore, gas-engines under such conditions would be more economical at the high-pressure atmosphere than at the low. Something of this kind has been experienced by gas-engine constructors where engines have been operated at high mountain levels; such engines usually experience not only loss of total power, but also some loss of heat efficiency.

In view of certain difficulties which are experienced, especially in large gas-engines of considerable cylinder dimensions, due to impossibility of securing equality of expansion of the metal parts in contact with the hot flame, it is interesting to consider what could be done by reducing cylinder dimensions and increasing mean pressures within a given cylinder. It becomes interesting, in fact, to consider whether there is no way of working at artificially enhanced atmospheric pressures, because it is obvious that such enhanced atmospheric pressures permit of great flame temperature reductions without requiring reduced maximum or mean pressures. With an atmosphere of double the existing density it is obvious that in a given engine mean pressures may be doubled, or, if desirable, mean pressures may be kept of the same value and flame temperatures reduced—that is, engines may be made much more powerful for a given cylinder diameter, and cylinder losses may be greatly reduced, not only by increased density, but by reduced temperatures capable of giving the desired pressures.

In small engines high temperatures may be used with comparative impunity, and, accordingly, we find with both coal-gas and petrol engines flame temperatures in the cylinder as high as 1,800deg. C. to 1,900deg. C. With larger coal-gas engines operating without water-cooled pistons and exhaust valves lower temperatures become imperative, and, accordingly, we find in such engines the maximum temperature reduced to 1,500deg. C., or a little under. Nearly all makers have been forced to recognise the necessity of reducing flame temperature with unwatered pistons and exhaust valves where the cylinders are of dimensions of the order of even 18in. diameter. In coal-gas engines, accordingly, the gas and air passages are so set as to produce a sufficiently dilute mixture to prevent the temperature rising unduly. In engines using producer gases of various kinds, the temperature is naturally somewhat lower than with coal-gas, so that special dilution is not so much required. This is also true of the very large engines using blast-furnace gas. In such engines, where the main constituent of the gas used is carbonic oxide, the flame temperature possible is not high, mainly because of the slow-burning nature of the carbonic oxide and the small heat value per cubic foot of the mixture of blast-furnace gas and air. To study the question I have calculated out from a number of recent diagrams the flame temperatures attained in standard engines of various types under the conditions found by the respective makers to give the best economy.

Fig. 3 shows diagrams taken from engines operating with coal-gas by well-known makers—Messrs. Crossley, the National Gas-Engine Company, and an engine built by Messrs. Fielding and Platt and experimented with by Prof. Burstall. From these diagrams it appears that the maximum temperatures range from 1,500deg. C. to over 1,900deg. C. Fig. 4 shows similar diagrams taken from engines using producer gas obtained from Dowson, Wilson, and Mond producers. Fig. 5 shows a series of diagrams taken from a very interesting tandem double-cylinder double-acting engine erected by Messrs. Richardsons, Westgarth, and Co., Limited, at Middlesbrough at the

In the producer-gas diagrams the temperatures, it will be observed, vary from 1,300deg. to 1,650deg. The blast- observed that the mean pressure obtained is somewhat low—70lb. per square inch, or under.

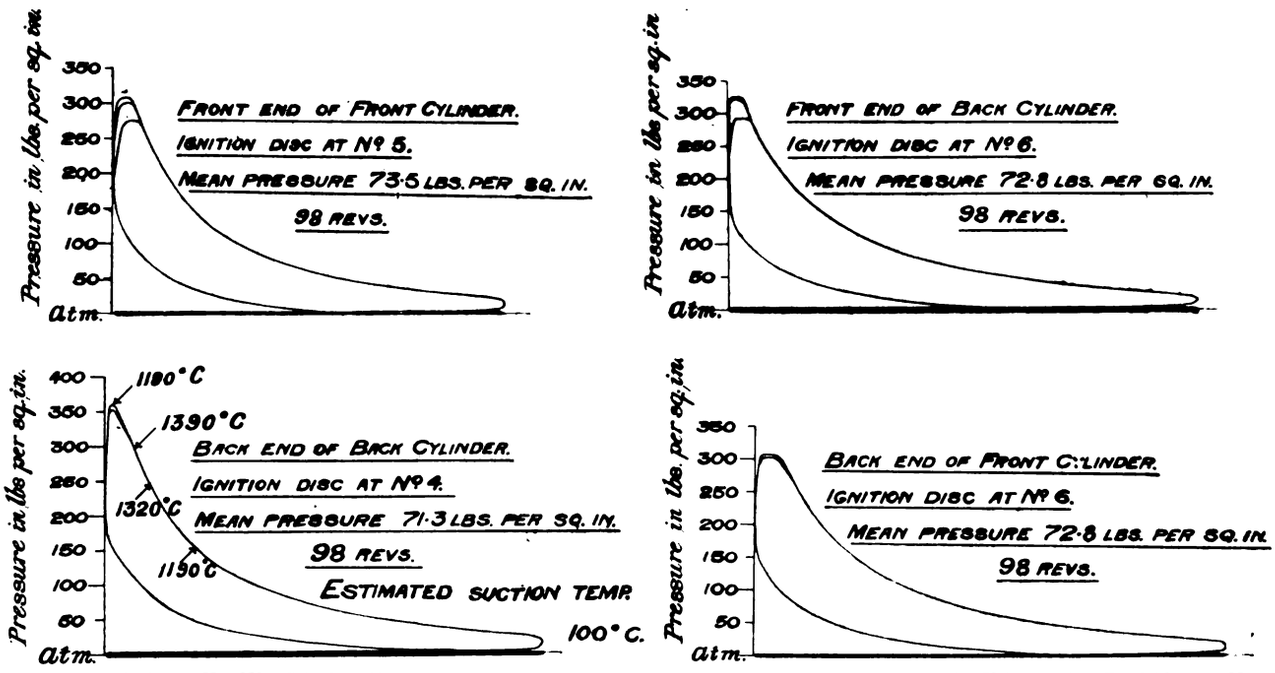
Digitized by Google

Two years ago it appeared to me possible to reduce the maximum temperatures to 1,200deg. C., or something near that figure, while maintaining a mean pressure only heretofore possible with high temperatures. My idea was to increase the atmospheric pressure artificially, in order to work under conditions which would permit of any desired mean pressure without requiring a corresponding flame temperature. For this purpose I experimented with two engines—one of 7in. diameter cylinder by 15in. stroke, and the other 10in. cylinder by 18in. stroke.

its return stroke. The suction valve of the engine had to be closed a little earlier than usual to prevent the added charge of air from blowing back into the supply pipe. The exhaust valve, too, in this experiment had to be opened a little earlier to prevent the exhaust gases passing up the overrun ports. With this engine I am able to study the effect of adding an air charge to a charge drawn into the cylinder without altering the amount of gas drawn in.

Two diagrams are shown at Fig. 6. One diagram shows the ordinary diagram such as the engine gives without

FIGS. 5.



Gas-Engine, Cochrane No. 250. Cylinders, 29½in. dia by 35½in. stroke. Piston rods, 7¼in. dia. Mean m.p. of 4 cards = 72·6lb. sq. in. Total i.h.p. at 98 revs. = 810. Indicator diagrams taken on July 15, 1904, with temporary load on dynamo. Diagrams handed to author by Mr. Westgarth.

The 10in. by 18in. engine arranged for these experiments is one of the ordinary four-cycle type operated with coal-gas. At the outer end of the stroke the piston over-runs a number of ports placed all round the cylinder, leading into an annular space which is carefully water-jacketed. Two sets of experiments were made with this engine. In one set an additional charge of air was used to increase the pressure within the cylinder after the ordinary charging stroke was complete. The air was compressed by means of a pump driven by belt from the flywheel of the engine. This air

added air. It is not quite as good, however, as the usual diagram obtained from this type and size of engine, as the alterations have slightly impaired the efficiency. The thermal efficiency, however, calculated from the indicator is 27·7 per cent. The usual results obtained from this engine show a thermal efficiency of 28 7 per cent. The other diagram with added air shows clearly the increase of efficiency due to dropping the temperature. The addition of air here increases the thermal efficiency of 27·7 to 34 4, while the temperature falls from about 1,700deg. to

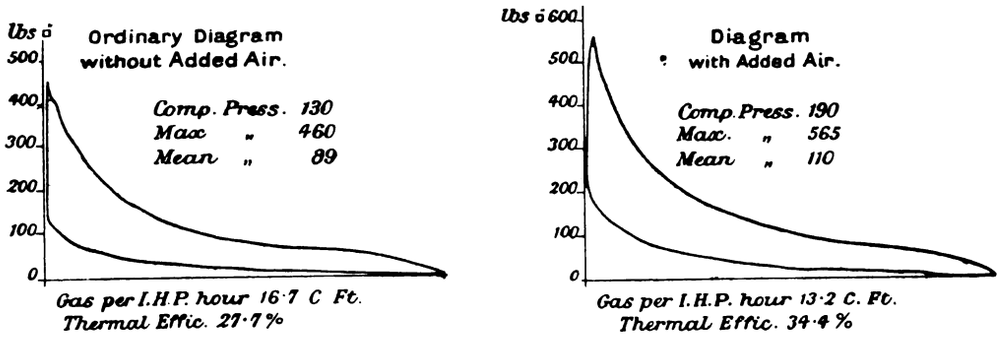


FIG. 6.—Average Diagrams from 10in. by 18in. National Engine.

was passed into a reservoir, and the reservoir was connected to the annulus in front of the engine cylinder by a pipe. A piston valve was provided operated from the engine-valve shaft, which valve opened at a proper time to fill up the annulus. This annulus was thus filled with air when desired at a determined pressure. The valve actions were so arranged that when the piston over-ran the ports, just completing its charging or suction stroke, air was discharged into the cylinder by way of the ring of ports so as to fill up the cylinder to nearly the pressure in the reservoir, during the time the piston was crossing the ports in completing its out stroke and closing the ports in beginning

1,200deg. The real improvement effected by the addition of air is better taken as compared with 28·7, the ordinary efficiency, rather than 27 7. A substantial improvement, however, is here shown—about 20 per cent. on the diagram. In this particular experiment, the brake power with added air is, of course, considerably increased; but as the compressing pump was attached in an entirely experimental way, the results of the brake tests made during the experiments are not of much interest.

Another set of experiments were made on this engine, in which the additional atmosphere was supplied without a separate pump by means of the exhaust gases passing from

Digitized by Google

the engine itself. In this experiment the same engine was used with the annulus and ring of ports at the front end of the cylinder, but here the piston valve was so operated in conjunction with the exhaust valve that the exhaust gases under pressure from the cylinder were allowed to pass through the front ports by way of a cooled pipe to a reservoir, and the opening of the ordinary exhaust valve was adjusted to discharge into the reservoir exactly the amount of exhaust required to give the desired exhaust pressure. At the end of the suction stroke, before the out end ports are over-run, the piston valve opens to the cold end of the reservoir, and shuts off communication to the hot pipe. Cooled exhaust products thus fill the ring, and, discharging into the cylinder, bring the pressure up to the artificial atmosphere desired.

Fig. 7 shows three diagrams with particulars marked under them taken from this engine under these circumstances. The upper diagram is the power diagram; the lower two diagrams show on a scale of one-fortieth and one of one-tenth the effect of adding the exhaust charge under pressure. In this case, comparing the best results obtained with the engine by Prof. Robinson in his test found at p. 254 of his book, we find an increase of 5 b.h.p., an improvement in indicated efficiency, increasing the indicated thermal efficiency from 28·7 to 32·5 per cent., and an

Brake thermal efficiency, 27·5 per cent. Test made by author with Ashton gas; 566 B.T.U. at 32deg. F. gas temperature, lower value. A later test with slightly diminished combustion space gives 27·2 brake h.p. Indicated thermal efficiency, 34 per cent. Brake thermal efficiency, 29 per cent.

improvement in the brake efficiency from 25 to 27·5 per cent. This improvement is obtained entirely by adding exhaust products under pressure to increase the weight of charge present, to increase the pressure before compression, and to diminish the flame temperature. This method of exhaust super-compression has the great advantage over air super-compression that no additional pumping is required. There are certain advantages, however, to be obtained from the use of air super-compression, notwithstanding the addition of a pump, and these advantages have induced the National Gas-Engine Company to build an engine (shown at Fig. 8) to carry out the fundamental idea of reducing flame temperatures while increasing mean pressures. This engine is intended to indicate 300 h.p. when working with producer gas of about 150 British thermal units per cubic foot. The idea is to keep up mean pressures while keeping down flame temperatures in order to avoid the well-known liability of heavily loaded gas-engines to overheating and pre-ignition. The engine is now at work with a weaker gas, and diagrams are shown at Fig. 9. In this engine the back end of the cylinder is arranged as a four-cycle motor of normal type; the front end is arranged as an air-pump, and is closed with cylinder cover, through which a piston rod passes from a cross-head guide of usual construction. One air-valve is operated at the pump end from the cam shaft. On one back stroke a charge of air is taken into the cylinder, the valve is closed, and on the out stroke this air charge is compressed into a reservoir forming the clearance space between the piston and the cylinder head. Ports over-run by the piston communicate with this clearance space, which is well water-jacketed, and the pressure causes the air to flow into the cylinder when the charging stroke is nearly complete. In this way the pressure of the charge is raised to about 7lb. per square inch.

The pressure in the front reservoir is raised to about 16lb. per square inch, as is shown upon the diagram, but the fall is only sufficient to raise the pressure within the cylinder to about 7lb. above atmosphere. The reservoir still contains some air at a little above 7lb. pressure, and this air is used on the next exhausting stroke to act as a scavenging air charge to displace the exhaust products from the cylinder and secure that no exhaust remains to form part of the further charge. The engine is thus not only a super-compression engine, but it is a scavenging engine. The pump side is arranged to draw air in on one stroke only—that is, the valve only opens once in two revolutions. One air charge is sufficient both for the purpose of super-compression and scavenging. Calculation from the diagrams proves clearly that a high mean pressure of over 100lb. per square inch is obtained with the very low maximum temperature of 1,200deg. C. The effect of this reduction of temperature in the smooth working of the engine is most remarkable. The tendency to pre-ignition or overheating is found to be entirely absent. Notwithstanding the fact that no watered piston is employed, the engine runs with perfect certainty at full load, with consecutive ignitions, at 160 revolutions per minute. So far as my experience goes, no engine of these dimensions without a watered piston could run at an average pressure of over 100lb. per square inch without difficulty due to pre-ignitions. So far, my attempt to use higher atmospheric pressures has succeeded. It has allowed increased load for a given cylinder and permitted consecutive ignitions at full load and speed without requiring any water cooling of the piston. It appears probable that temperatures may be still further reduced with advantage, especially in operating large gas-engines.

I need not inform the body of engineers before me that the difficulties with which the large gas-engine is at present struggling, are in main due to the high temperatures of the flame in the interior of the cylinder. So long as high-temperature flames are used within cylinders of relatively small dimensions, the difficulties due to unequal expansion of parts does not appear. The steam engineer is well aware of the care which has to be exercised in using large steam-cylinders in such a way as to avoid cracking, and he can quite well imagine that the difficulties of allowing for free expansion in a gas-engine cylinder are much more serious than his own when he considers the relatively low temperature of his steam. Even with superheated steam, 300deg. C. is a fairly high temperature, while in existing gas engines of either large or small types it may be taken that the lower limit of maximum temperature at present is nearly 1,400deg. C. The water-jacketing of a moving piston is an admirable expedient most carefully and ably carried out by many Continental and English engineers; but it is an expedient which has never satisfied me, and is, I believe, regarded with distrust by a considerable number of English engineers. In my view many of the troubles which have been experienced with large gas-engines—cracking pistons, back covers, and the like—are due to the difficulties introduced of getting rid of very large heat flow through cylinder and piston walls, and it appears to me desirable, if possible, to reduce this flow to the lowest point consistent with maintaining the economy of the engines. In doing this, of course, it will not do to reduce the mean pressures of the engines. Large gas-engines are at present undesirably heavy for the power as compared with steam-engines, and it will not do to increase the weight in any way by reducing the temperatures. This

Digitized by Google

plan of artificially raising atmospheric pressure, either by the addition of air under pressure or by the addition of cooled exhaust gases under pressure, appears to me to furnish a very promising solution of the problem. In gas-engines operated with producer gas or blast-furnace gas the question of maximum possible economy is not at present a pressing one. The thermo-dynamic efficiency of all gas-engines is now so much greater than any heat efficiency attained in steam-engines that we can well afford to reduce economy, if need be, in order to make more certain of good practical results—that is, to make more certain of low cost for upkeep and repairs. In my view it would pay in large gas-engines even to reduce fuel economy if by so doing entire immunity from breakdown was secured. So far the best means of limiting temperature in a simple way appears to be found in the addition of cooled exhaust gases to the charge before compression; and this method, although reducing flame temperature, has actually increased the efficiency instead of diminishing it. This is quite evident from the figures shown with reference to air and exhaust super-compression diagrams found at Figs. 6 and 7. The results obtained with the 10in. by 18in. engine are, so far as I am aware, the best heat efficiencies ever obtained from a gas-engine of the dimensions. It will be noted that the exhaust super-compression indicated efficiency is 32½ per cent., while the air super-compression indicated efficiency is 34·4 per cent. The exhaust super-compression thus appears to give slightly lower results than the air super-compression in the same engine. Theoretically, under equal conditions, the efficiencies should be the same for either air or exhaust gas additions. No doubt the cause of difference is due to a somewhat smaller clearance space which was used in the engine while the air experiments were in progress. It would have been interesting to compare the heat efficiency of the large air super-compression engine with the smaller one, but unfortunately I have not been able yet to instal apparatus for making accurate measurements of the producer gas supplied to this large engine. The results obtained I will have pleasure in publishing later.

In bringing forward this question of flame temperature in gas-engines, both large and small, I must not be understood to depreciate in any way the efforts of those able Continental and English engineers who have made so brilliant an advance in the application of the large gas-engines to producers and blast-furnace gas within the last few years. The present position of the large gas-engine in Britain is due to the work of Thwaites, Hamilton, Crossley, Atkinson, and Humphreys in England, and that of Delamere Debautteville, Krafts, Koerting, Oechelhauser, and the Deutz Company on the Continent, while Westinghouse has contributed his share of work in America. The progress made in solving the large gas-engine problem is a notable one, and most creditable to all these able engineers and firms. Nothing is to be gained, however, by over-estimating our present position either with regard to large or small gas-engines. With small and moderate engines, no doubt, it may be considered with truth that all the problems have been solved, and that in these engines, not only on the point of heat efficiency, but also in all points of reliability and low cost of repairs, the gas-engine more than holds its own with the steam-engine. This cannot yet be said, however, of the really large gas-engine. At present these engines are in a state of somewhat rapid change, and the types upon the market are so numerous and varied that they are engaged in a struggle of which the fittest will survive. This question of flame temperature, however, affects them all, and much will be gained if engineers will frankly recognise flame temperature as a matter to be dealt with in itself instead of merely providing palliatives to neutralise the effects of high flame temperatures when generated. The advance in the knowledge of the theory of internal-combustion motors has made it quite clear that so long as flame temperatures are higher than temperature of adiabatic compression, so long will the full thermo-dynamic efficiency be attained for a given compression. This fact, however, barely requires restatement; it is so largely recognised by all gas engineers.

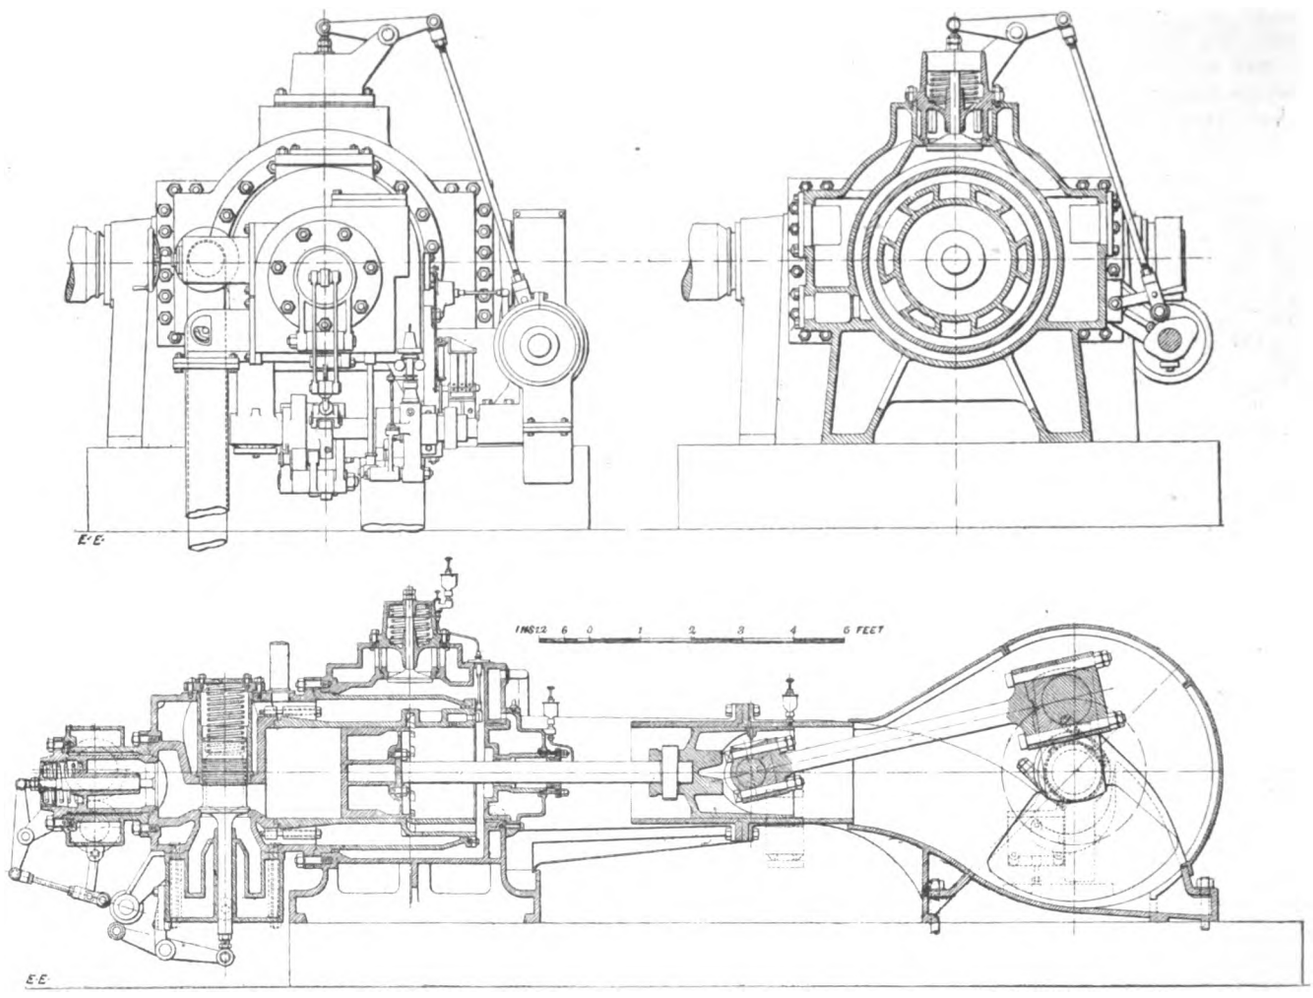

FIG. 8.

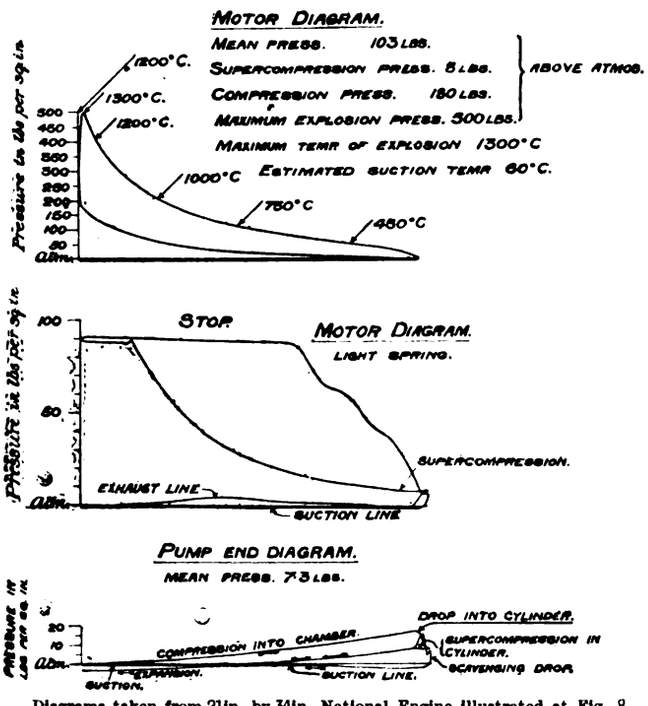
In Britain at present we are fortunate in having before us examples of all the leading internal-combustion motors of the world, large or small. British makers are now occupied in building, among large gas-engines, those of the Cockerill, Ochoelhauser, Koerting, and Westinghouse types, while other English firms, such as Crossley Bros., the National Company, and the Premier Company, are producing large gas-engines of British invention on British lines. Indeed, some of the Continental engines may also be said to be operated on British lines, because both the Koerting and the Oechelhauser engines are really modifications of the Clerk cycle invented and operated in this country over 20 years ago. From this it will be seen that British makers are no longer neglecting—if they can be said to have ever neglected—the large gas-engine problem. So far as small and moderate gas-engines are concerned, British engineers have a very long lead. From information supplied me by many English firms, I estimate that there have been manufactured and sold from Britain alone some 100,000 stationary gas-engines, the average power being something like 20 h.p. The present output of gas-engines in Britain is very large. It at present amounts to at least 200 engines per week. This includes

FIGS. 9.



Diagrams taken from 21in. by 34in. National Engine illustrated at Fig. 8. Revs. at test, 160 per min.

stationary gas and oil motors, but takes no account of petrol motors for cars. So far as these engines are concerned, the British position could not be improved upon. In the large gas-engines, too, the problem is being seriously attacked. I had the pleasure of visiting the works of Messrs. Richardsons, Westgarth, and Co., Limited, a couple of weeks ago, and inspecting at Middlesbrough and Leeds a number of large engines built by them. They show a very interesting installation of seven Cockerill engines coupled to blowing cylinders in one engine-house. These engines are rated at 600 h.p. each, so that this one engine-house contains 4,200 h.p. of gas power for using blast-furnace gas. The engine installation is practically complete, and will be in operation when the scrubbing plant for the gas is finished fitting up. Messrs. Richardsons, Westgarth, and Co. also showed me a tandem-cylinder double-acting gas-engine of very interesting construction, from which the diagrams shown at Fig. 5 have been taken. This engine was shown to me in operation at the works of Messrs. Cochrane, of Middlesbrough, driving a dynamo. It worked with all the steadiness of a steam-engine, and the governing was effected by varying the gas admission, keeping compression constant, so that two impulses were given to the crank at every revolution under all circumstances, light and loaded. This is a most interesting engine, which promises very well. I also inspected two single-cylinder single-acting Cockerill engines of 250 h.p. at the pits of the Yorkshire Coal and Iron Company, near Leeds, where they were driven by coke oven gas, also an interesting installation.

This question of flame temperature appears to me, perhaps, the most important and fundamental at present before engineers engaged in the design of these internal-combustion motors. It is fitting that this branch of the subject should be considered before the British Association, and assistance is particularly desirable from physicists who have interested themselves in temperature measurements, especially high-temperature measurements. The determination of these flame temperatures is one of great difficulty, and the data available are very incomplete. Certain assumptions have to be made, for example, as to the temperature of the total charge at the moment of filling the cylinder before compression begins. The only serious attempt to determine this charge temperature has been made by Prof. Burstall in the very able experiments conducted by him for the Gas-Engine Research Committee of the Institution of Mechanical Engineers. In arriving at the flame temperature numbers given in this paper, I have made free use of Prof. Burstall's results to enable me to assume some reasonable temperature for the "suction temperature," as Prof. Burstall calls it. The whole of this subject requires investigation, and new methods require to be discovered to enable the determination of the suction temperatures to be easily made for every experiment. I am glad to say that a committee of the Institution of Civil Engineers has been formed to attack the whole question of the thermo-dynamic standard for these engines; and, among other points, I hope that this point of flame temperature and its determination will be duly considered. There can be no doubt that in these times, when internal-combustion motors are being applied to every purpose of motive power both on land and sea, the scientific problems, which, after all, are fundamental and necessary to rapid progress, require much more serious consideration than has been yet given them.

In addition to the figures referred to, the paper is illustrated by a large number of photographs and sections of large and small gas and oil engines.

THE SPECIFIC HEAT OF GASES AT HIGH TEMPERATURE.*

BY PROF. H. B. DIXON.

Prof. Dixon gives in his paper a description of some original work carried out at Manchester on the above subject. The paper was not in manuscript, and the following is a brief abstract of the author's description of this work. Dealing with the combustion of gases, Prof. Dixon showed that carbon monoxide would not burn at a very high temperature. This fact tended to keep down the temperature after explosion. He had experimented on the specific heat of gases on the bomb method. The bomb was first heated when empty and dropped into a calorimeter. It was then filled with CO and again dropped in. By means of differences the specific heat of the gas could be calculated. It was difficult, however, to use this method for temperatures over 400deg. C., owing to the steam given off when the bomb was dropped in. Instead, he had developed a method of determining this specific heat from the velocity of sound through the heated gas. He used a tube for this purpose which could be uniformly heated, and obtained the following results:

Temperature.	Ratio of specific heats. Air.	CO.
15deg. C.	1·398	1·314
100deg. C.	1·395	1·29
200deg C.	1·390	1·25
300deg. C.	—	1·19

It will be seen from this that the specific heat of carbon monoxide decreases considerably with the temperature. Prof. Dixon is carrying his experiments up to higher temperatures. He also dealt in his remarks with the explosive pressure in a confined space. Bunsen has shown

* Abstract of paper read before the British Association at Cambridge.

Digitized by Google

that this pressure was only one-third of what would be expected. The reason for this had been attributed to a rapid rise of specific heat, and also to incomplete combustion. Photographs taken in a glass cylinder by Prof. Dixon showed that the combustion was by no means instantaneous. The flame actually travelled the full length of the cylinder and half way back before the pressure began to rise.

Discussion.

The discussion on Mr. Dugald Clerk's paper and on the one by Prof. Dixon was commenced by Prof. B. Hopkinson, who said that there must be a considerable amount of stratification in the gases in Mr. Clerk's engine. The normal proportion of air to gas is 9 to 1. Mr. Clerk added extra air, making the mixture 14 to 1, which was very near the non-explosive point. The rapid explosion shown by the diagram, therefore, indicated stratificaticn. Prof. Hopkinson attributed the loss of heat referred to by Prof. Dixon to a turbulent motion in the gases caused by the explosion. He thought that the energy was converted into kinetic energy in the moving gas, which was then again converted into heat at the cylinder walls.

Sir Andrew Noble referred to the behaviour of explosive mixtures under pressures of from 500 to 5,000 atmospheres. This resulted in very high temperatures, with the result that carbon monoxide would not burn to carbon dioxide. He concluded from the results of experiments that this specific heat of gases was very much less at high temperatures.

Prof. Schuster, of Munich, congratulated Mr. Clerk on the success of his experiments. He knew of an instance in Germany where the temperature in an oil-engine cylinder had been successfully reduced by the injection of small quantities of water. It was a happy idea of Mr. Dugald Clerk's to use the products of combustion as the inert material to reduce the temperature. He had experimented some two years ago on Prof. Hopkinson's calorimetry method of testing gas-engines, and had secured accurate results within 2 or 3 per cent.

THE CALORIMETRY OF EXHAUST GASES.*

BY B. HOPKINSON.

So far as I am aware, in all gas-engine tests hitherto made, the indicated work, the heat in the cooling water, and the calorific value of the gas used are the only quantities which have been directly measured. The balance of heat unaccounted for has been put down to exhaust gases, radiation, and conduction. In some cases an attempt has been made to separate the last-mentioned items by estimation, but these attempts have been very rough in character, and have led to very divergent results. The special point of the tests to be described is that the exhaust gases were passed through a calorimeter, and so cooled to near atmospheric temperature, the heat rejected by them being measured. In this way a complete heat account has been obtained, in which the only item not directly determined is the loss by conduction and radiation.

The first set of tests were made on a Crossley engine in the engineering laboratory, Cambridge, of somewhat old pattern, giving about 5 h.p. on the brake. The following are the particulars of the engine: speed, 250 revolutions per minute; cylinder diameter, 7½in.; stroke, 9in.; compression space, 143 cubic inches; ignition, hot-tube with timing valve. Cylinder only is water-jacketed, piston and exhaust valve being uncooled. Cambridge coal gas was used, having an average calorific value of 680 British thermal units at 0deg. C. and 760mm., of which about 70 British thermal units are the heat evolved in condensing and cooling the steam produced in the explosion.

The calorimeter for the exhaust gases is shown in Fig. 1, from which its construction will sufficiently appear. It consists of a section of flanged cast-iron pipe fitted with baffle plates, by which the gases are caused to pass several times backwards and forwards through its length, and finally to bubble through the water collected at the bottom. The water, after passing through the jacket surrounding the calorimeter, meets the exhaust gases in a fine jet, and is partly caught by them and carried round with them, and partly trickles down the baffle plates. It was found that in this way the gases could be cooled, with the engine fully loaded, down to 120deg. F. or less, the cooling water rising in temperature from about 60deg to 90deg. This instrument was designed of ample proportions, so that it should be certain to work satisfactorily; there can be no doubt that it is big enough to serve for a much larger engine. In a test on an engine of double the power—to be described later—the calorimeter was very much smaller and the results quite satisfactory.

There is no need to particularise the methods of indicating the engine or of measuring the amount and temperature rise of the jacket water, about which there was nothing peculiar. Some pains, however, were taken to secure accurate measurement of heat put into the engine. The gas was measured with a wet and dry meter in series, and both meters were calibrated with a standard holder at the rate of flow of gas actually used. The calorific value of the gas was determined with a Junker calorimeter at the time of the test on the engine. The amounts of heat stated as having been supplied to the engine are probably correct to within 2 per cent. The results obtained are given in Table I. The fifth column is an estimate of the energy still left in the exhaust gases after passing the calorimeter in those cases in which it is not negligible. It is based on the assumption that the volume of gas discharged per cycle is that of the engine stroke, corrected for the suction pressure (observed) and the suction temperature (assumed), and that these gases are saturated with water vapour. Their temperature is observed, and thence can be calculated the heat which they would evolve (by cooling and condensation of steam) on cooling to 80deg. F., which is about the temperature at which the gases leave the Junker calorimeter.

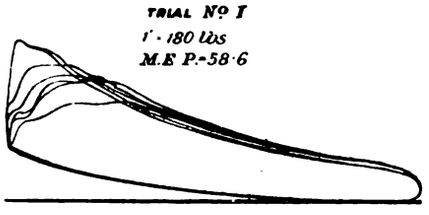
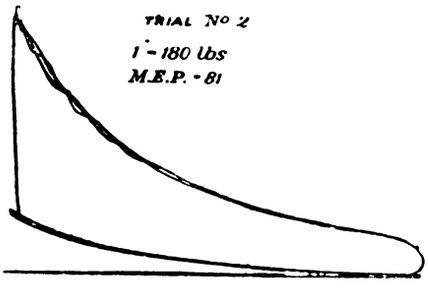
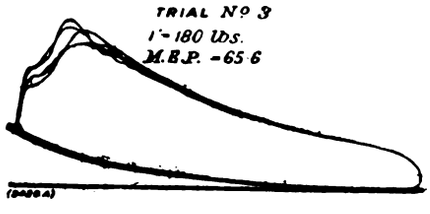
9	15·2	2·65 = 17½	5·7	4·2	0·4	2·2 = 14½	111	52	7·0	1,200	100	82	144	Late ignition.

All the figures are stated in British thermal units per explosion and the first four columns need no further explanation.

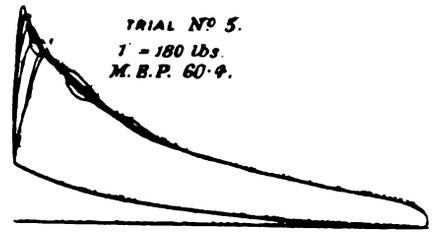
This estimate is a very rough one, as the volume may be in error by 10 per cent. in certain cases, and the gases may not be fully saturated; but the item is a very small one. The sixth column shows the balance unaccounted for, and consists of the radiation and conduction losses, and the sum of the errors in the first five columns. In the first three trials, as appears from the seventh column, there was no load on the engine, and practically all the explosions were preceded by one or more scavenging strokes. In the other trials the engine was nearly fully loaded, so that very few of the explosions were preceded by a scavenging stroke. The release pressure

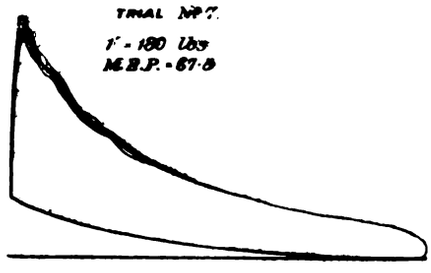


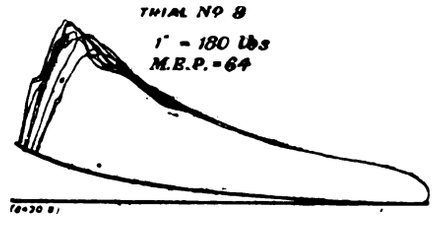




in the eighth column is the pressure at a point one-tenth of the stroke short of the out-centre at or about which point the exhaust valve begins to open. The energy of the gases at release is calculated from the release pressure on the assumption that we have then perfect gas mixed with the steam produced by the explosion, the amount of which is known from the gas analysis. The heat of condensation and cooling of this steam is added to the heat in the gas considered as perfect gas. The actual energy is probably more than this, since the steam and CO_2 are almost certainly somewhat dissociated at the temperature of release. In the tenth column are the temperatures of release. These are calculated from the suction temperature (assumed) and release pressures. In the case of the light-load trials the suction temperature cannot be far different from the temperature of the gas before admission, and I have taken a round figure of 27deg. C. or 300deg. absolute. In the full-load trials the suction temperatures are very uncertain. I have drawn on Prof. Burstall's measurements for these, and have assumed a round figure of 77deg. C. (350deg. absolute) for Nos. 4, 5, 6, and 7, and 127deg. C. (400deg. absolute) for the others in which the release temperatures are higher. It will be seen that the temperature measurements are extremely rough, but I have only based conclusions on their relative order of magnitude in the several trials, and that is, no doubt, correctly shown. The "liner temperature" is that of the







outer end of the cylinder liner where it projects in front of the cylinder. Since this portion is not water-jacketed, is not exposed to the flame, and is in all trials except No. 5 hotter than the jacket water, it must receive its heat entirely from the piston, which comes into contact with it on the out centre. Its temperature is, in the case of the full-load trials, a rough indication of the heat being given to the piston. In trials Nos. 3, 8, and 9 the ignition was retarded, so that it commenced about one-thirtieth of the backward stroke after the in-centre. In the other trials the ignition was normal, and commenced slightly before the in-centre. The following points are worthy of note:

1. The gases lose much heat between release and entering the calorimeter. Table II. shows the difference between the estimated energy at release and the energy given to the calorimeter, and sent up the exhaust pipe. The actual difference is greater, since, as already

Digitized by Google

explained, the energy at release is certainly underestimated.

TABLE II.

Number of trial	1	2	3	4	5	6	7	8	9
Release temperature	780	870	930	900	800	880	880	1250	1200
Temperature of passages	cold	cold	cold	hot	hot	hot	hot	hot	hot
Loss in passages	2·4	2·3	2·1	1·8	0·8	1·6	1·9	2·8	2·4

The gases lose heat after release, partly in the exhaust valve and passages, and partly to the cylinder walls in the exhaust stroke of the piston. The latter part of the loss goes to swell the jacket losses; the former is largely radiated away from the hot exhaust valve. We should expect the amount of loss to depend mainly on the difference of temperature between the gases and the passages or cylinder walls. Thus, high-release temperatures should mean much loss of heat, and in the light-load trials, where the passages are fairly cool, the loss should be greater than in the full-load trials, where they are kept hot. The conclusions are confirmed by the last table. The smallest losses are in trials 4, 5, 6, and 7, where the release temperature is low, and the passages hot. Then come Nos. 1, 2, and 3, where, though the release temperature averages about the same as in 4, 5, 6, and 7, the passages are cold and the losses undoubtedly higher. Finally, we get the largest losses of all in Nos. 8 and 9.

2. The balance unaccounted for (column 6 of first table) seems to consist mainly of radiation from the exhaust valve. The biggest balances are those in trials Nos. 8 and 9, where, by reason of the late ignition, the release temperature is high. The exhaust valve in these trials was observed to be very hot. It will be noticed that in these cases the temperature of the liner, and therefore of the piston, was lower than in the other full-load trials, and the temperature of the jacket water was by no means excessive. In No. 5, although the jacket water was nearly boiling, the balance is low, because here the exhaust valve was fairly cool.

3. There is no marked improvement in efficiency caused by scavenging.

4. The piston is cooler with the late ignition. Compare the liner temperature of Nos. 8 and 9 with the other full-load trials of Nos. 4, 6, and 7.

One object of these trials was to ascertain whether a practical method of testing gas-engines for efficiency could be based on the calorimetry of the exhaust gases. At the present time manufacturers are mainly concerned with making their engines reliable; the thermal efficiency, being with any design far and away better than in the steam-engine, is a secondary consideration. But it cannot be doubted that in the future gas-engines will have to be as closely tested for efficiency as steam-engines now are. Now to measure the heat put into a large engine worked with producer gas is a very difficult and costly undertaking. The volume of gas is very great, and its quality may vary largely in the course of a day's trial. It seems to me that it may be easier and more accurate to measure the indicated work and the heat rejected, as is usually done in testing a steam-engine. One large part of the rejected heat—that is, the heat in the jacket water—presents no difficulty; we have therefore only to measure the heat carried away in the exhaust gases. The only question is whether the balance of heat unaccounted for, which cannot be measured, is too large a percentage of the total heat. From this point of view the tests made on the small Crossley engine are not very satisfactory, the heat unaccounted for in the full-load tests ranging from 8 to 16 per cent. of the total. Moreover, in those tests the calorimeter was very much more bulky than was necessary for the purpose. It appeared to me from consideration of the results that the lost balance of heat must have gone mainly in radiation from the exhaust valve and other uncooled parts of the engine. I therefore made a similar trial on a second and larger engine in the laboratory, in which, as it had a water-cooled exhaust valve, it appeared probable that the radiation loss would be substantially less. This engine is by the Forward Engineering Company, and gives about 10 h.p. on the brake. The following are the principal particulars of it: speed, 250 revolutions per minute; cylinder diameter, 7in.; stroke, 15in.; compression space, 140 cubic inches; ignition, hot-tube with timing valve. Cylinder and exhaust valve are water-jacketed, piston being uncooled. This engine compresses to 115lb. absolutely against 70lb. in the Crossley. In the case of this trial the exhaust-gas calorimeter was made very much smaller. Fig. 2 sufficiently shows its construction. The water is sprayed through two flat-flame gas burners into the exhaust pipe, so that the exhaust gases immediately on leaving the engine encounter a sheet of cold water, and they are further cooled by churning up the water at the bottom of the calorimeter. The gases, after leaving the calorimeter, were taken into the ordinary exhaust box of the engine, which was provided with a drain and acted as a water separator. It was found, however, that very little water was carried over from the calorimeter by the gases. With this apparatus the gases were cooled down to a temperature of 120deg. F. or less, the engine being fully loaded, and the apparatus itself occupied but very little more space than the bit of exhaust pipe which it replaced.

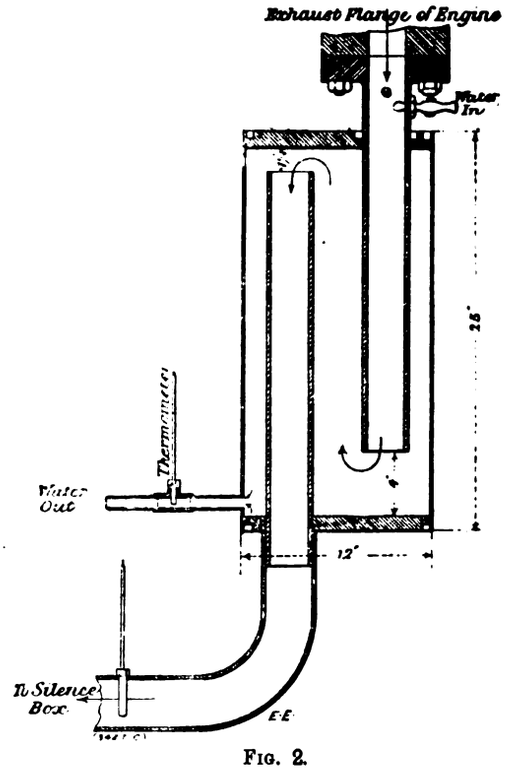


FIG. 2.

The following are the results of a trial made on this engine:

TABLE III.

	B.Th.U. per explosion.	Per cent.
Jacket water	7·0	32
Exhaust calorimeter	7·5	34·5
Heat up chimney (estimated)	0·3	1·5
Indicated work	5·7	26
Balance unaccounted for	1·3	6
Heating value of gas used	21·8	100·0

Temperature of exhaust gases after passing calorimeter, 107deg. F. temperature of jacket water at exit = 105deg. F.; explosions per minute, 106; indicated horse-power = 14·2. The gas measurement in this trial is correct to within 2 per cent., the indicated power is correct to within 5 per cent., and the other measurements to within 2 per cent.

It will be seen that the heat lost by radiation and conduction certainly does not exceed 10 per cent. of the heat put into the engine, and is probably a good deal less. I have made a large number of trials of the same kind on this engine, in all of which the balance unaccounted for is less than 6 per cent., even when the jacket water was very hot. This seems to me a sufficiently good result to justify trying this method of testing engines on a larger scale, especially having regard to the very compact character of the exhaust-gas calorimeter. In ordinary steam-engine trials it requires extraordinary precautions to get a closer agreement than this between the heat put in and the heat rejected, plus indicated work. Moreover, I think it is reasonable to suppose that in a large engine with a water-

Digitized by Google

cooled piston, the loss unaccounted for would be smaller still. Of course, the precise design of the calorimeter for the exhaust gases would have to depend on the arrangement of engine and piping in each case; but there is no doubt, I think, that the secret of success is to spray a sheet of water under high pressure into the exhaust pipe close up to the engine. The gases rushing out break up this sheet into minute drops, and are thus very effectually cooled. The only difficulty then is to separate the suspended water from the gas, and to collect and measure its amount and rise in temperature. The separation is by no means so difficult as I had anticipated, and could no doubt be effected in a box somewhat similar to that which I have shown in Fig. 2. It will be found, on calculating out the heat contained in the gas after leaving the calorimeter, that this item does not become seriously high so long as the temperature of the gases is below about 140deg. F. I find, however, that the radiation and conduction from this particular calorimeter become rather large at temperatures above 115deg. But it is easy to determine the amount of this by a separate experiment.

I append some typical indicator diagrams, sufficient to show the character of the explosion in each case. The whole of the experiments were carried out at the engineering laboratory, Cambridge, by my pupils, Messrs. G. Harrison and A. Blackie, of Peterhouse. They also reduced most of the observations, and I wish to express my indebtedness to them.

THE EFFECTS OF RECEIVER DROP IN A COMPOUND ENGINE.*

BY JOSEPH W. HAYWARD, M SC., CENTRAL TECHNICAL COLLEGE, SOUTH KENSINGTON.

This paper deals with the results of four experiments undertaken to demonstrate the effects of varying the point of cut-off in the low-pressure cylinder of a compound engine, other conditions being maintained constant. The tests were made at the Central Technical College. The engine employed was of the horizontal compound surface-condensing type, with cranks set at right angles; its high-pressure cylinder is fitted with an expansion valve, whose travel is controlled by the governor; its low-pressure cylinder is also fitted with an expansion valve, the lap of which was set to give the cut-off required for each experiment. The cylinder constants for this engine are as follows:

Cylinder.	H.P.	L.P.
Diameter (inches)	8·728	15·76
Stroke (inches)	22	22
Mean volume described by piston per stroke (cubic feet)	·7463	2·4485
Mean clearance volume (cubic feet)	·076	·1364

During the trials the barrel of each cylinder was jacketed with steam at boiler pressure, and the receiver was drained

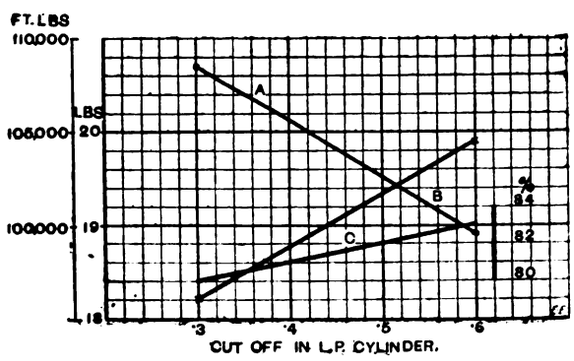

FIG. 1.

continuously through a steam trap. The shortest experiment lasted 1¼ and the longest 4¾ hours. A summary of the results appears in Table I.

Fig. 1 shows lines plotted between periods of admission to the low-pressure cylinder as abscissæ, and the following as ordinates: (*a*) work done upon the pistons per pound of steam used; (*b*) pounds of steam used per indicated horse-power per hour; (*c*) mechanical efficiency of engine.

* Paper read before Section G, British Association, Cambridge.

TABLE I.

Trial number	79	81	78	80
1 Cut off in low-pressure cylinder, front	·29	·39	·5	·62
,, ,, ,, back	·31	·41	·5	·58

* The resistance of a short line of countershafting is included in the engine friction.

The work done upon the pistons per pound of steam decreases continuously as the receiver drop increases, but the consequent loss is partially counterbalanced by an increase in mechanical efficiency. It was quite noticeable that the engine worked more smoothly during trial 80 than during trial 79, and, even with the latest cut-off used, more than half the power was developed in the low-pressure cylinder. The mean indicator diagram for the extreme trials, 79 and 80, are given in Fig. 2, and the same diagrams, reduced to a common scale of volume occupied per pound of working steam, are reproduced in Fig. 3.

Although the range of temperature in the high-pressure cylinder was 88deg. F. in trial 80, as against 62deg. F. in trial 79, the steam was 3 per cent. drier at 80lb. pressure in the former case than in the latter. This increase in dryness appears to a smaller extent in the intermediate trials (see Table I., line 13). It may be accounted for by the fact that condensation in the steam-

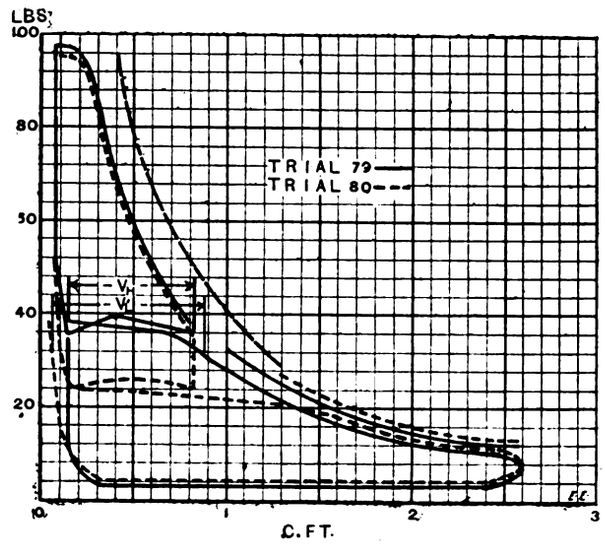

FIG. 2.

pipe and high-pressure valve chest is a function of the time alone; consequently, the greater the quantity of steam passing through these the drier a given weight of that steam will appear. In the low-pressure diagram for trial 80 the result of free expansion and reduction of temperature range is evident.

One of the chief difficulties in making comparable trials is to maintain the glands in the same condition throughout. Unfortunately, the packing in these was excessively tight

Digitized by Google

during trial 79 and excessively loose during trial 81. In the former case, the back pressure was reduced to 3·0lb. per square inch with a hot-well temperature of 135deg. F., but the mechanical efficiency fell to 80 per cent. In the latter case, the mechanical efficiency rose to 84 per cent., but the back pressure was 3·8lb. per square inch, with a hot-well temperature of only 130deg. F.

In a recent paper dealing with "receiver drop"—see *Proceedings* of the North-East Coast Institution of Engineers and Shipbuilders, vol. xvi., 1900—Prof. Weighton states that, "For maximum economy of consumption, steam must be cut off at a certain point in the stroke in the larger cylinders of multiple-expansion engines. For any given cylinder this point depends solely upon the ratio between the capacities of that cylinder and the preceding cylinder, R, and is expressed as follows—viz.,

$$\frac{\text{Maximum economy cut-off}}{\text{stroke}} = \cdot 15 + \frac{I}{R}"$$

The general application of this conclusion to all engines is not borne out by the experiments under discussion. Prof. Weighton's formula gives the best point of cut-off at ·46 of the stroke, whereas Fig. 1 shows that it is not later than ·3 of the stroke.

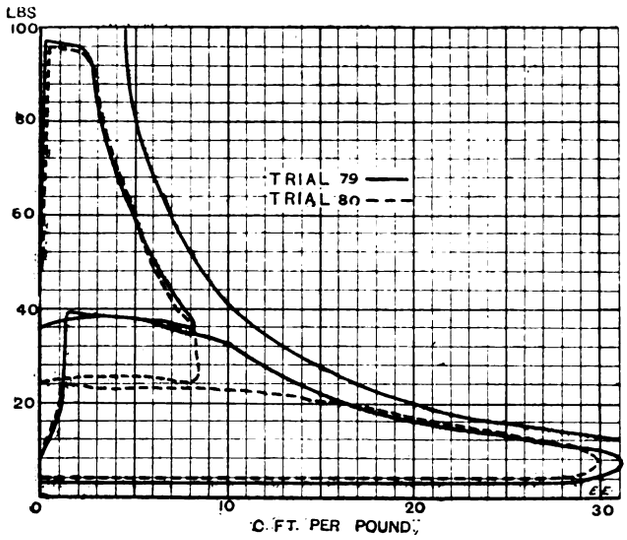

FIG. 3.

The author considers that the amount of clearance volume and the extent to which compression occurs in both cylinders of a compound engine must have an important influence over the receiver drop, and consequently over the best ratio of expansion in the low-pressure cylinder. For example, in trial 79 the volume, V_H (see Fig. 2), of the working steam after its expansion in the high-pressure cylinder was ·69 cubic feet. The volume, V_L, of the same steam at cut-off in the low-pressure cylinder was ·83 cubic feet.

$$\frac{V_L}{V_H} = 1{\cdot}20.$$

Had there been no compression, this ratio of free expansion would have become 1·15, and had there been neither clearance nor compression, it would have become ·99. A change in the above quantities in one cylinder only would have a still more marked effect. It is hoped that by further experiment evidence of the true extent of these influences may be obtained.

THE ACTION OF LIGHTNING STROKES ON BUILDINGS.*

BY KILLINGWORTH HEDGES, M.I.C.E., HON. SECRETARY, LIGHTNING RESEARCH COMMITTEE.

In a paper entitled "The Protection of Buildings from Lightning," which was read at the Glasgow meeting of the association in 1901, the author mentioned the establishment of the Lightning Research Committee, organised jointly by the Royal Institute of British Architects and the Surveyors' Institution, who have since investigated a very large number of occurrences from the reports furnished by their observers. It was decided after the first year to confine the committee's investigations to buildings which were fitted with conductors, and, following this course, the reports on about 40 protected buildings affected by lightning have been summarised by a sub-committee, and are having the attention of the General Committee, who will in due course issue a report.

The principal causes of the failure of the usual style of lightning rod as fitted on the buildings investigated, appear to be due to the following: (1) insufficient number of conductor and earth connections; (2) the absence of any system of connecting the metallic portions of the buildings to the lightning conductor, especially the interconnection of the finials, rain-water pipes, and gutters. In the author's opinion the frequent damage by side-flash from the conductors might be lessened by running a horizontal conductor along the ridge, or along the parapets of all the roofs, somewhat after the method which is almost universally adopted in Central Europe.

The lightning strokes may be divided into three classes: (1) Those where the conductor conveyed a portion of the flash to earth, but the side-flash to other unearthed metallic conductors damaged the building; the practice of running the conductor round the projecting masonry, often taking sharp bends, doubtless facilitated the deviation of the current from its direct path to the earth. (2) In several observations a metallic roof of large area received the flash, consequently became highly charged, and the single conductor failed to convey the whole of the stroke, a portion of which took a circuitous path—for instance, through a speaking-tube and an electric bell wire. (3) A flash struck the building at two points simultaneously, a lightning conductor taking one part of the stroke, but damage was caused by the other portion selecting an unprotected part of the roof.

Earth Connections.—With a few exceptions, these had the defect common to nearly all earth-plates which are simply buried in the ground close to the foundations of a building, and owing to drainage soon became dry, consequently are of very high resistance. Architects, as a rule, object to sufficiently deep holes being made near a structure; consequently the permanently moist ground is not reached. The tubular earth designed by the author does away with this objection, and can be kept moist by leading a small tube to the nearest rain-water pipe.

Interconnection with the Metal Work of a Building.—Although the utility of the external metal was specially put forward in the report of the Lightning Rod Conference in 1882, their recommendation has been apparently disregarded in all the cases under review. The Cavendish Laboratory (No. 64) stroke, which was fortunately unattended with danger owing to the gas in the gas-pipe which formed the path of the current being turned off, would have not taken this circuitous path had the leaden roof been connected to the conductors which ran down the tower only, also to the rain-water gutters and pipes, which should have been interconnected at the bottom and properly earthed. Again, at Bedford (No. 88) last year, St. Paul's Church was seriously damaged by the flash leaving the single conductor on the tower by the water on the roof and passing thence to earth by means of the rain-water pipes. In this case it is interesting to note that the lead pipes were not fused, but their round section was changed into an oval one; the iron water-pipes were broken. This incident and No. 68 (St. Pancras Church, Euston) show clearly that the damage was due not to direct stroke, but by a portion of the flash leaving the main conductor and taking a circuitous path round the unconnected metal work outside and inside the buildings.

Observation No. 2: Kea Church, Truro.—The copper sheathing of the spire, owing to its great capacity, could not discharge through the one excellent conductor to earth, consequently the flash divided, part going by the conductor and part by the alternative path formed by the copper covering of the spire to a rain-water pipe, thence sparking through a parapet wall to lead flashing down another pipe, and then along a very small copper wire used for training

* Paper read before the British Association at Cambridge.

Digitized by Google

plants, to the main conductor. Similar effects were noted in Stoers Lighthouse (No. 54) and Devaar Lighthouse (No. 56), the divided flash in the former leaving the conductor for a telephone wire and in the latter for a speaking-tube. In these observations the conductors may be said to have acted to a certain extent, and if the structures had been entirely unprotected the damage would have been greater, but by proper attention to the necessities of each case, and increasing the number of the conductors, the risk would probably be nil, as there would be a definite path for the lightning to take.

Quite the most interesting case is that at Possingworth House (No. 67), struck in June and again in August, 1902, although the roof fairly bristled with air terminals, every chimney being protected, mostly with its own conductor and earth connection. It is probable that on the second occasion the flash divided, one part selecting a chimney stack, which it damaged, bending the air terminal to an angle of 45deg., while the other, neglecting the many points, fell on an unprotected statue much lower than the chimney and went to earth by the iron frame of a conservatory, showing the unreliability of a number of independent conductors which should have been interconnected by means of a horizontal wire led along the ridge; this would in all probability prevent any serious damage.

Sir Oliver Lodge has shown by an interesting experiment that a column of hot air is often selected by a flash although a lightning rod may be affixed to the side of the chimney. Most of our large stacks have a band of metal to which the air terminals are fitted, and from these two conductors should be led to earth. The method adopted in Germany appears to be simpler, and consists of a heavy iron frame rising to a sufficient height above the stack, and continued at the apex so as to form an aigrette. That lightning may prefer the smoke issuing from a chimney was shown by the stroke at the East London Waterworks, Sunbury, last year, the flash doing some damage to the capping before it arrived at the standpipe inside, which was a perfect earth in that it was in direct connection with the company's mains.

The general conclusions arrived at by the author are that there is very little advantage in placing isolated rods on an ordinary building without it has a high tower. A church, for instance, with a spire should have at least two conductors from top to earth. Even then, if any other part of the structure happens to be in the path of a discharge from a cloud to the ground, the stroke may disregard the protected towers or spire and fall on the building, choosing some lower point. If the suggestion put forward by Sir Oliver Lodge at the Bath meeting in 1888 were more closely followed, and the conductors so arranged that they form a protective network over all the roofs, a flash would in all probability be received by some portion of the system and pass without harm to the ground by one of the numerous earths to which the network would be connected.

The insurance offices appear to disregard the question of adequate protection, and are quite content if the single conductor which has not prevented serious damage, for instance, to a church is replaced, and, moreover, take no steps to have the earth connection tested periodically; also the few unconnected lightning rods erected on our national museums, picture galleries, and other public buildings contrast most unfavourably with the more scientific methods adopted on the Continent, more especially in Germany, where in some districts the local authorities have issued rules as to the erection and testing of lightning conductors, to which the various public bodies have to conform, and in some cities householders are subject to penalties if the system is allowed to get out of order.

REVIEWS.

The Steam-Turbine. By ROBERT M. NEILSON. Longmans, Green, and Co. 10s. 6d. net.

We have a lively recollection of being present, some 16 to 18 years ago, at—what was then a complete novelty—the first starting up of a Parsons steam-turbine. Our recollection is vivid, inasmuch as the speed of the machine was the—then unheard of—figure of 16,000 revolutions per minute, and on this speed being attained, the attendant hum was so alarming that most of those present, including the writer, incontinently fled. Since that day our knowledge of turbines has increased and speeds have been brought to more moderate values, except in the De Laval.

The literature of the steam-turbine is more or less scanty, and is scattered about in various publications. Engineers owe the author of the present volume a debt of gratitude for bringing into a compact and reasonable compass the history, theory, and latest practice of steam-turbines. The historical part is treated with admirable restraint, whilst the theory and practice is dealt with in a manner that renders it most valuable. The evolution of types is carefully traced showing the gradual weeding out of the unfit, until the Hon. C. S. Parsons enters the field in 1884, which, as it were, marks the epoch from whence the steam-turbine as a practical machine may be said to date: the progress since that time has been one of steady growth, and now it is all the fashion, if not the rage.

We are introduced to the theoretical work by a useful chapter on the "Points of resemblance and difference between the steam-turbine and other motors," and from the considerations there given one feels that the steam-turbine ought to score in efficiency "hands down"—whether it does so or not in practice will appear later. Incidentally we should like to point out a statement that appears somewhat ambiguous. It occurs on p. 58 and reads: "It should be borne in mind, however, that in a multiple-expansion turbine like a Parsons, *heat produced by friction raises the temperature of the steam and increases its energy*" (the italics are ours). The meaning—viz., that some portion of the heat of friction is recovered—we think might with advantage, especially to students, be rendered more simply and direct.

The chapter on vanes and velocities is good in the treatment of the subject matter, but the style is far too diffuse, with consequent lack of power, even in places leading to statements that are illogical—*e.g.*, on p. 74 we have

"Let the velocity . . . . . be represented by V_1 and the radius . . . . . by R_1.

Therefore velocity at any radius $r = \frac{V_1 \times r}{R_1}$."

In this same chapter we have a most tiresome reiteration of the word *therefore*, the effect on a reader trying to grasp the argument being irritating to a degree.

That controversial subject, entropy, is dealt with in a commendably brief chapter—we say commendably brief, because in our opinion it might have been omitted without loss. It may be heretical to say so, but we have never found "entropy" of any practical use. Prof. Perry, as the author tells us, calls it a "ghostly quantity." The truth of this description becomes apparent when the more or less intelligible statement, $d\,Q = \tau \times d\,\phi$, is put into words. We quote from Chapter vi., p. 82: "When heat is put into or taken out of a substance, any small part of the heat so dealt with is equal to the temperature at which it was put in, or taken out, multiplied by some quantity. This quantity is called change of entropy."

Advantageous as the steam-turbine is in many respects on the score of economy of steam, it does not shine greatly as would be imagined. From the test figures given on p. 199, we see that a 500-kw. turbo-alternator at full load and with 27·8in. vacuum gave a result of over 25lb. of steam per kilowatt. Recently the writer obtained with a 250-kw. reciprocating engine-alternator 24·4lb. of steam per kilowatt, 25in. vacuum, and no superheat, and we believe that only in large sizes—1,000 kw. and upwards and a 29in. vacuum—can the steam-turbine compete in steam consumption with a good reciprocating engine. As we have previously stated, this is hardly what would be expected, showing how much room for improvement there is remaining.

There are many interesting points that could be dealt with did space permit, but we must refer those interested in the subject to the book itself. We can cordially recommend it, it is full of valuable information, is well printed, and is illustrated with such a wealth of clear diagrams and blocks that make it a real pleasure to read.—G. W. G.

GAS-ENGINES.

Many years ago the late Sir Frederick Bramwell prophesied that steam-engines would in a certain time become extinct, and that they would be replaced entirely by the internal-combustion engine. His belief in his prophecy was so strong that he left the sum of £100 in order that a lecture might be given at the end of the period which he prophesied would be required for this radical engineering change to be effected. The developments of recent years lead one to believe that the gas-engine is likely to succeed in the future in ousting steam-engines at least for power purposes on land. With the increase in size of gas-engines, however, numerous mechanical difficulties have been met with which were predicted beforehand, and which tend to neutralise the advantages from the higher thermal efficiencies of the engines. Chief amongst these is the cooling question. The quantity of heat in a cylinder immediately after explosion is proportional to the volume of the charge, or, to put it roughly, to the cube of the engine dimensions. On the other hand, the cooling surface which is available for keeping the engine parts at reasonable temperatures only increases as the square of the dimensions. The result is that means of cooling which are quite effective in small engines become insufficient when the size and output is increased. In consequence, builders of large engines have found it necessary to provide water-jackets not only round the cylinder, but also in the cylinder ends, and even in the piston itself. In his interesting paper before the Mechanical Section of the British Association, Mr. Dugald Clerk described a new method he had invented for improving gas and oil engines in this respect. The paper is given in full in this week's issue, and is well worthy of careful study. In it it is clearly shown that the exceedingly high temperatures found in ordinary cylinders immediately after explosion is uneconomical for two reasons. In the first place, it is higher than the range of expansion in an ordinary engine can utilise, and hence results in the exhaust gases being too hot and carrying away an unduly large proportion of the heat. Secondly, it causes the mean temperature of the inside of the cylinder walls to be unnecessarily high, and hence increases the loss of heat into the jacket water. Mr. Dugald Clerk's invention consists in introducing at the end of the charging stroke a certain amount of inert gas under pressure. This raises the pressure of compression, but, owing to the presence of the inert gas, the temperature after explosion is greatly reduced — for instance, in one special case the temperature of the gas was reduced from 1,700deg. C. to 1,200deg. C. The curious point which will be of great interest to theorists on the perfect heat engine, is that with this reduction of maximum temperature there is an increase in the actual thermal efficiency of the engine of from 27·7 per cent. to 34·4 per cent. In the paper will be found a description of the ingenious method adopted by Mr. Dugald Clerk of abstracting a certain portion of the exhaust gases under pressure during the working stroke and returning the same into the cylinder after cooling at the end of the charging stroke. It is true that the engine has a few more parts, but the increase in output, as well as in the thermal efficiency, quite warrant extra expense. Thus, with a given engine the output was increased from about 23 b.h.p. to 28 b.h.p.—*i.e.*, over 20 per cent.—by returning a small portion of the exhaust gases into the charge, as explained above. Again, quite apart from the increased efficiency in output, we find a big reduction in maximum temperature, which with engines of a large output will decrease the trouble of cooling the working parts

Digitized by Google

and increase the life of the same. On the same morning at Cambridge, Prof. B. Hopkinson read a paper on the "Calorimetry of Gases exhausted from an Internal-Combustion Engine." This we are also reproducing, as it should be studied simultaneously with Mr. Dugald Clerk's communication and the abstract of Prof. H. B. Dixon's remarks on his experiments on the specific heats of gases at high temperatures. These three communications were the subject of joint discussion of the most interesting character, in which theory and commercial practice were both referred to. For instance, Sir Andrew Noble carried the subject of the properties of gases after explosion up to the pressures and temperatures of that earliest form of gas-engine—the gun. Lord Kelvin gave some interesting remarks on the theory of combustion, with the result that the morning of Friday, Aug. 19, was the most instructive one spent in Section G during the Cambridge meeting.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

MISMANAGEMENT OF THE BRITISH ASSOCIATION MEETING.

SIR,—With great pleasure those of your readers who were at the British Association this year will notice your censure of the organisation of Section G. Is it not an extraordinary thing that of all the sections into which the British Association is divided, the engineering section, which is that most closely connected with the commercial world, should show the most lamentable lack of business principle? So much is this the case that I notice in the special articles contributed to the *Manchester Guardian* by their Cambridge correspondent, twice—viz., on Tuesday and Thursday, Aug. 16 and 18—the engineering section is singled out as *the* badly-organised section. "The engineering programme appeared to have been arranged for the last three days by shuffling or balloting, Friday having the only syllabus which showed signs of intelligent forethought and arrangement," says this correspondent with strong common-sense, and all who were there will feel the truth of the statement. How was it, I may ask, that on Monday morning, for instance, the authors of the first two papers were allowed to read *in extenso*, from end to end, their contributions, instead of giving a reasonable *résumé*, with the result that papers quite as valuable, like those of Sumpner and Weekes, Thornton and Dr. Fleming, had to be rushed through without even time for a proper *résumé*, some with no discussion at all. How is it that with a committee boasting men of business and a recorder connected with a large engineering firm, such a medley as Wednesday's programme could have been put together? Last year exactly similar complaints were made, and I know that I am only voicing the opinion of many regular attendants of Section G when I say that steps should be taken to prevent such a muddle occurring again.—Yours, etc., B. A.

RE ARTIFICIAL LOADS.

SIR,—Your correspondent "Yrreb" has devoted so much attention to me in your last issue (one letter and parts of another) that I am compelled to acknowledge his lavish courtesy. Possibly, like Micawber, he finds relief for a surcharge of emotion in letter-writing.

I have very carefully considered the oil-can theory, and fully agree that if one did drop an oil-can between the electrodes of a water resistance, marked changes of load would occur. I must, however, reject this charmingly original suggestion on the ground that one cannot keep on dropping oil-cans into the tank. The unsteadiness of load was a recurrent phenomenon occurring during the use of running water.

I cannot claim the profundity of special knowledge that is vouchsafed to "Yrreb," but write as a general practitioner with a particularly unpleasant experience of the use of canal water for a testing tank. I am, however, only too glad to sit at the feet of "Yrreb" or any other sage so long as he has something useful to impart, and does not carp at other workers.

I admit that the tank suction was in the wrong place—it was in the canal. If we had taken it up to the fountain head, we might have got some decent water in place of the dilution of mill effluents we had to put up with. We did as well as we could, practically, and used the town supply.

As regards my capabilities and the measure of success which I have obtained, I am afraid I must leave that matter to those who by their actual acquaintance with me are more fitted than "Yrreb" to indulge in personal criticisms.

Finally, I would suggest to "Yrreb" that when he next seeks to accentuate the importance of his own publications by trying to depreciate the value of another man's work, which appeared to be the motive of his first letter, he should pay for his epistle at the usual advertisement rates.—Yours, etc., A M.I.C.E.

WIRELESS TELEGRAPHY.

SIR,—I notice that Mr. Blaine in his article on "Wireless Telegraphy" on p. 200 of your issue of Aug. 5, accredits the De Forest system of wireless telegraphy to Dr. Lee De Forest and Prof. C. E. Freeman. I merely wish to call your attention, and the attention of Mr. Blaine, to the fact that the receiving device or responder, which is the particularly novel element of the system, is due to Mr. De Forest and myself, as will appear from the copies of the United States letters patent 716,000, 716,203, and 716,334 of Dec. 16, 1902, which I am mailing you under separate cover.—Yours, etc., EDWIN H. SMYTHE.

Chicago, Aug. 16, 1904.

LETTERS FROM AN OLD HAND TO A YOUNG ONE.

VI.—ON THE TIME-ELEMENT.

MY DEAR YOUNG 'UN,—H. G. Wells has written a remarkable little story, which I daresay you have read, called the "Universal Accelerator." You will remember that a doctor invented a stimulant which affected every part of the body exactly equally, so that no out-of-balance strain was thrown upon any portion, the result being that for a time the whole existence of the man under the influence of the decoction was accelerated; he could think, act, speak in a thousandth of the time usually taken. Great stress was laid on the immense advantage which a man under this stimulating influence would have over his *entourage* which moved and thought at ordinary rates; and one finished the story with a half-sigh for the impossibility of the realisation of the dream of quick life. Behind the grotesqueness of the story lies one of the prime factors of success—rapidity; smartness. It is the hustler who gets the contracts nowadays. Our forefathers thought they were going strong when "Puffing Billy" did 10 miles an hour. Now we have rival electrical firms seeing who can break their necks quickest on the Marienfelde-Zossen railway at anything up to 120 miles an hour. Once upon a time contractors went slowly and did careful work. Nowadays they cannot, because "Time to be the essence of the contract" is written on every specification.

The Time-Element, then, is one of the most potent factors in your success or failure, and I want you to get hold of the importance of being "right *there*"—toe on the line, waiting for the starting pistol, whenever you begin to do anything.

In the shops where I was inducted into the mysteries of engineering there was no five minutes' grace after six o'clock. You had to be in on the stroke, or else the gates were slammed in your face and you lost a quarter. That was all right; but there was the added terror of an old Scotch foreman who was always there 10 minutes before time and kept his eye on the apprentices. When asked his opinion about a sluggard who was just able to squeak in as the gates closed, he would say: "Nae dom gude! Snoops

in at the wicket like a lawyer gaein' ta heaven!" Which remark was very galling on a frosty morning, but was useful in impressing on us that in order to retain our places in the ever-increasing ranks of the army of engineers we had to *keep step*.

Now the pace is so fast in modern engineering, that in order to be up to time at the various points on the route one must do a considerable amount of bucking-up. There are two ways of getting along in a race: one is to scramble, the other is to scud. The man who scrambles generally gets a stitch in the side and sits down suddenly. The man who scuds begins to enjoy himself after he has got his second wind. But you can only scud when you have been in training for some time and are thoroughly fit. It is no good "slommocking" through engineering; you must train yourself to do things with a snap.

When a warship goes into action two or three preparations are made. All useless impedimenta—things likely to catch fire or get in the way—are thrown overboard. The decks are cleared for action and everything made snug; nothing is let flopping about for the enemy to make a mess of. Then provision is made to serve the guns with ammunition at the quickest possible rate, and the ship goes in with full steam up. If you have made up your mind to be above all things a successful engineer, don't try to be a footballer, an artist, a comic singer, and a husband as well. All these are good in their way, but a man of ordinary capacity for work hasn't time for them all; his movements will be hampered. Keep your ammunition where you can use it. In the bad old days a fitter could spend half the morning looking for his tools. There is no use for that man in the modern shop. He draws his heavy gear from the tool store, his ordinary kit is kept in tool racks; and if he doesn't work smartly, he gets the sack. Arrange your knowledge; index your notebooks. Store your technical papers after throwing away the advertisement leaves, and keep the index handy. Classify your books, so that you can turn up any subject at once.

I knew the chief of a lighting station who, when he wanted an item of information, used to make hay with the papers on his desk for a quarter of an hour before he found the scrap he was after. He wasn't a quick worker.

Classify your brains as well. Don't have a lot of vague ideas floating about, but nail them down under headings.

And, finally, keep your steam up; if you don't, your propeller will go slow, you will lose "way" and won't answer your helm. If you find your attention flagging in study in spite of well-meant efforts to concentrate, bustle out of doors and take a sharp walk. If you have a bicycle, do your reasonable best to get a hot bearing on the cyclometer. You need all the constitution you have got in order to satisfy the time-conditions of present-day engineering.—Yours, THE OLD 'UN.

THE ELECTRICAL CONDUCTIVITY OF CERTAIN ALUMINIUM ALLOYS AS AFFECTED BY EXPOSURE TO LONDON ATMOSPHERE, AND A NOTE ON THEIR MICROSTRUCTURE.*

BY ERNEST WILSON.

The physical properties of certain light aluminium alloys have formed the subject of communications,† and, as stated therein, a specimen of each alloy was placed on the roof of King's College, London, in order to investigate the effect of exposure to London atmosphere. The specimens are in the form of wire 0·126in. (3·2mm.) diameter, and were placed on the roof on June 11, 1901. They have been taken down in July of each of the years 1902 3 4, and their electrical resistance measured. The results are set forth in Table A.

It was shown that during the first two years' exposure the series of copper-aluminium alloys (Nos. 16, 4, 13, 14, 15) diminished conductivity to a greater extent the greater the percentage of copper. It will be seen that this process has progressed still further, but the yearly variation is not now so great as during the first year. This last year's exposure still confirms the conclusion previously arrived at, that copper alone should not be used in fairly large quantities when alloyed with aluminium to be exposed to London atmosphere. Of the nickel-copper-iron-aluminium alloys (Nos. 20, 21) the former (No. 20) has changed

* Paper read at the British Association, 1904.

Digitized by Google

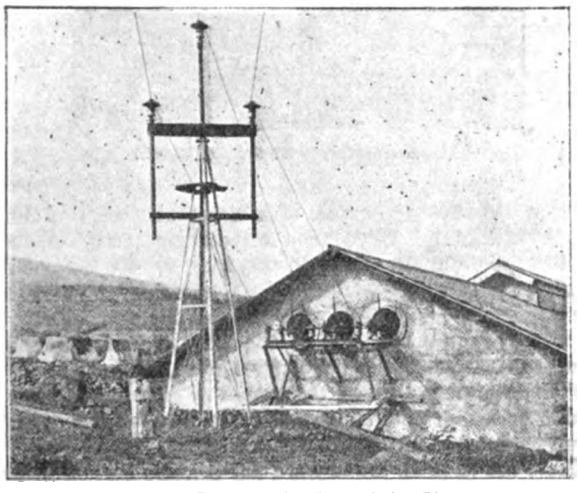
comparatively little, and it is richer in nickel; the latter (No. 21) is richer in iron and shows a gradually increased rate of deterioration. Each of these alloys has a comparatively high tensile strength. The nickel-copper-aluminium alloy (No. 22), which showed such remarkably increased tensile strength as compared with good commercial aluminium, has now (like No. 21) considerably diminished total conductivity. On the other hand, the manganese-copper-aluminium alloys (Nos. 10, 9, 23) have suffered comparatively small diminution in conductivity, and No. 23 has a comparatively high breaking load. The iron-copper-aluminium alloy (No. 24) has also shown little change in conductivity during the three years' exposure, and its breaking load is considerably higher than that of good commercial aluminium. The alloys (Nos. 17 and 20) have also suffered small diminution in electrical conductivity.

It was thought that an examination of the structure of these alloys by aid of micro-photography might throw some light upon the great difference which exists between some of their physical properties. Alloy No. 22 has a breaking load of 45,900lb. per square inch, as compared with about 28,000lb. per square inch for ordinary drawn commercial aluminium. After grinding and etching with various solutions, practically no structure could be discovered under a magnification of 800 diameters. Considering the remarkable crystalline structure exhibited by ordinary commercial aluminium near the surface of an ingot when allowed to solidify at an ordinary rate, the want of structure in these alloys may be attributed to the process of drawing down. The inference is that the great difference which exists between their tensile strengths and other qualities is probably not due to variation in structure.

I am indebted to the council of the Royal Society for a portion of the Government grant, which has enabled me to carry out these experiments in micro-photography, and I wish to acknowledge the help I have received from Mr. R. E. Shawcross.

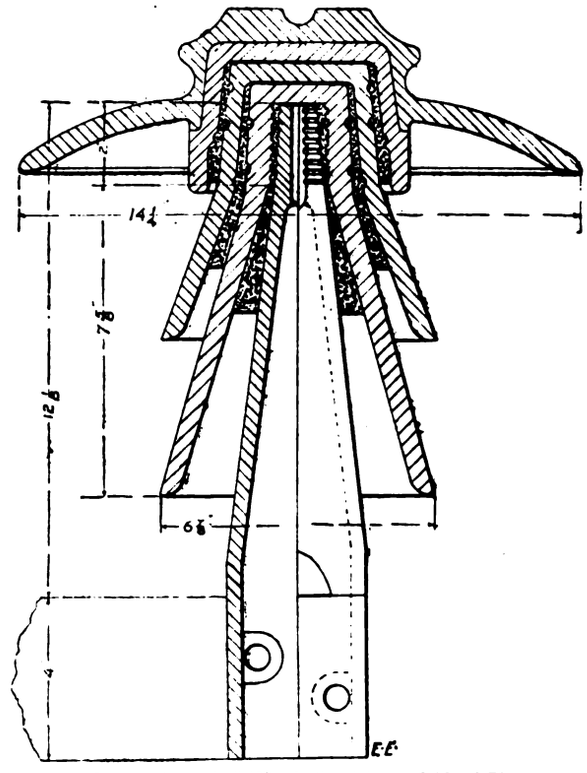
POWER TRANSMISSION IN MEXICO.

Some particulars are given in the *Electrical World* of New York of the 100-mile 60,000-volt transmission line of the Guanojuato power plant, which has been installed to supply energy for the mining and other industries of that city. American ingenuity and capital are responsible for the undertaking. The generating station is situated at the



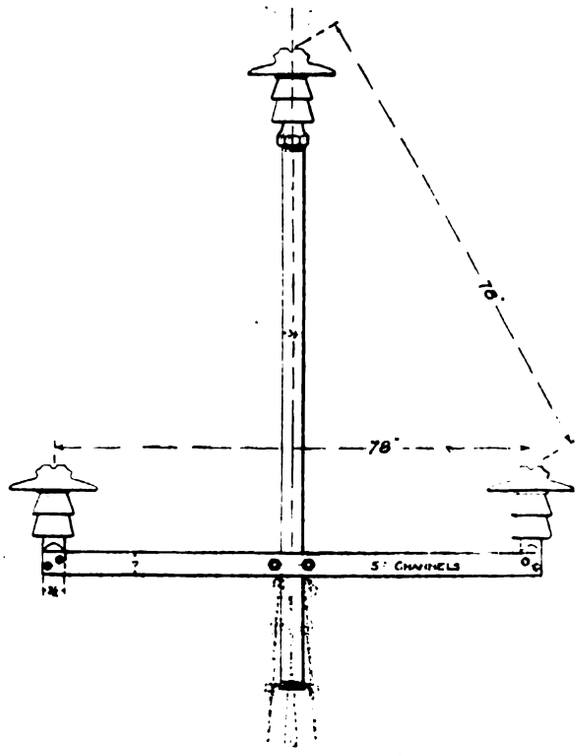
The First Tower of the Transmission Line.

little Indian village of El Platanal, near the city of Zamora, and for some 30 miles the line passes over rough mountainous territory, as it also does in approaching Guanajuato, but the intervening tract of about 60 miles consists of open country. The transmission apparatus is of a somewhat novel character, its distinctive features comprising the employment of metal pins, cross-arms, and special galvanised steel towers instead of strong ordinary poles for supporting the insulators, the substitution of hard-drawn copper cable in the place of the usual solid conductor for the transmission line, and the unusual length of the spans. While not exactly original, the design is probably unique in point of extent.



Cross-section of 60,000-volt Insulator and Metal Pin.

The conductors are 19-strand, hard-drawn copper cables about ⅜in. in diameter, equivalent in carrying capacity to No. 2 B. & S.G. wire, and weighing 1,340lb. per mile. This type of conductor was finally decided upon after much



Elevation of Cross Arm and Pipe.

study and many tests, because of its high conductivity, flexibility, and mechanical strength, the wires composing it having a tensile strength of over 55,000lb. per square inch. The cable was made and shipped in lengths of about two miles. The joints were made with special copper tube connectors 12in. long, and elliptical in cross-section. The two ends to be joined were passed through the connector in opposite directions, and three complete twists were given

Digitized by Google

by means of special wrenches. No soldering was done. The cables are placed in grooves on top of the insulators, 78in. apart, at the points of an equilateral triangle, and are tied in with No. 14 soft copper wire, it being considered that the small wire wrapped about several times would make an easy tie, and not be apt to damage the small hard-drawn strands of the cable. Diagrams showing the proper sag to be allowed at various temperatures and for spans up to 1,320ft. were prepared, based on a maximum strain of 20,000lb. per square inch in the coldest weather and with the most severe wind.

The towers are special 40ft., four-post, galvanised steel structures, weighing about 1,500lb., made of 3in. by 3in. by $\frac{3}{16}$in. angles, braced and stayed with smaller angles and rods. Each post terminates in an anchor, consisting of a piece of angle iron 30in. long secured at right angles. One of these towers is shown in the accompanying diagram.

The advantages of long spans, with consequent reduction in number of supports and of insulators required, were so obvious that it was at once decided to adopt that type of construction. After careful study and many calculations and estimates, the 40ft. towers spaced 12 to the mile were determined upon. The towers are spaced 440ft. apart, 12 per mile, except near Guanajuato, where the nature of the ground necessitated the use of a few 60ft. towers and spans up to 1,320ft. in length.

The No. 9 B.B. double galvanised iron wires for a telephone circuit are fastened on the transmission towers 10ft. below the copper power cables. They are tied to regular glass insulators placed on 12in. painted oak brackets bolted to tower legs. The telephone wires are transposed one complete revolution every four towers; the power cables are not transposed. High-resistance instruments are used, and the telephone service is quite satisfactory. The climatic conditions for high-voltage transmission are usually good, and during the dry season, when the water is lowest, and when all the losses should be kept at a minimum, the atmospheric conditions are very favourable.

We reproduce diagrams illustrating a cross-section of the 60,000-volt insulator and main pin and an elevation of cross-arm and pipe. The enterprise presented several local difficulties, but the task of harnessing the rapid and boisterous Duero was completed in about a twelvemonth, which is accounted distinctly a record for an undertaking of such magnitude in Mexico.

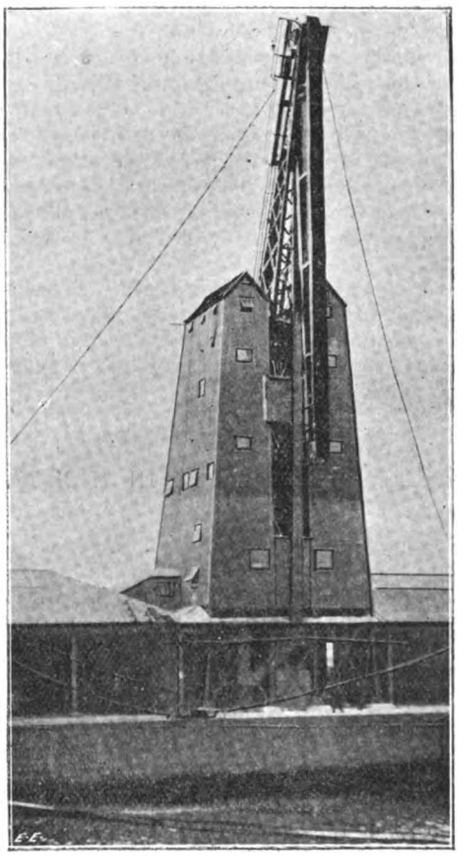
ELECTRICITY AND GRAIN ELEVATORS.

BY G. T.

The new grain elevator which has just been erected at Leith Docks demonstrates the great benefit to the owner by the adoption of motors. There are so many appliances to control in a narrow space that steam-engines would be impossible unless much more room was afforded in the designer's plans. As this is the first grain elevator to be built in Scotland, and as the likelihood is that others may follow, a description of the motive power will be of interest. The elevator tower is built of steel, and rises to a height of 78ft. The outside leg is that which lifts the grain from the ship's hold. It is lowered and raised by a balanced girder worked by a 5-h.p. motor. This girder is 84ft. long, and the combined weight of the outside elevator leg, girder, and balancing material is 60 tons. Yet it is handled with ease by one man in the conning tower, who has an electric switch at his hand, and can move about the 74ft. leg with its endless band of small buckets by a touch of the hand, without requiring to take his eyes off the ship's hold. He can swing the leg a distance of 27ft. from the quay wall, can lower the bottom to a depth of 31ft. below quay level, and can raise it until it is 44ft. above the quay level. The movements are noiseless, and the motor is on one of the platforms inside the narrow tower, and is reversible, with the drum alongside on which is coiled the wire rope.

A 50-h.p. motor is used for driving the endless band of buckets which scoop up the grain in the ship's hold and carry it to the top of the leg, whence it is shot down a tube to a receptacle at the bottom of the tower. Another motor, one of 40 h.p., is then turned on to move another endless band of buckets, which lift the grain to the top of the tower inside. There is also a 25-h.p. motor installed for operating the trimming gear in the ship's hold. That gear consists of four large shovels, which draw the grain from the far depths of the hold to the place where the buckets in the elevator leg are working. Smoothness and rapidity are the essentials in the working of these buckets, and they travel at the rate of 500ft. per minute.

There is a fifth motor in operation in connection with the elevator. This is used for driving the broad rubber band conveyor which carries the grain from the elevator tower to the warehouse. The distance is over 600ft., and therefore the pull on a 1,200ft. endless band of rubber weighing (without any grain) nearly two tons is considerable. The motor in this case is the most powerful, and is of 60 h.p. The current is obtained from the Leith Docks authorities, and the elevator is lighted by both arc and incandescent light. For the smaller elevator, which has been erected at some distance from the ship elevator, and is to be used for discharging lighters, there are also five small motors installed.



New Grain Elevator at the Leith Docks.

In the warehouse, which is a great structure of brick with bins like a honeycomb for receiving the grain, there are no fewer than 16 motors—viz., four of 40 h.p, one of 15 h.p., and 11 small motors each working up to 5 h.p. The large ones are necessary for driving the elevators which lift the grain to the top of the bins in the warehouse. These run at 640 revolutions per minute, giving a speed of 600ft. per minute; while the smallest motors are for the conductor belts, and run at 960 revolutions per minute. A motor works a swing lift capable of carrying 10cwt.

There are thus no fewer than 26 electric motors in position in connection with this new system of discharging grain at Leith. From first to last the grain is handled by motor power, and in the warehouse it travels along the whole length of the building, top or bottom, and can be sacked at the rate of 4,000 sacks per hour. The feature of the electric power installation is the skilful manner in which the space has been utilised and the wonderful ease in working. Messrs. Spencer and Co., Limited, of Melksham, fitted up the elevators; and Messrs. James Milne and Son, Limited, Edinburgh, supplied all the machinery in the warehouse.

THE BRITISH ASSOCIATION.

Address to the Mathematical and Physical Section.

BY PROF. HORACE LAMB, LL D, D SC, F.R S, PRESIDENT OF THE SECTION.

The losses sustained by mathematical science in the past twelvemonth have perhaps not been so numerous as in some years, but they include at least one name of world-wide import. Those of us who were students of mathematics 30 or 40 years ago will recall the delight which we felt in reading the geometrical treatises of George Salmon, and the brilliant contrast which they exhibited with most of the current text-books of that time. It was from him that many of us first learned that a great mathematical theory does not consist of a series of detached propositions carefully labelled and arranged like specimens on the shelves of a museum, but that it forms an organic whole, instinct with life, and with unlimited possibilities of future development. As systematic expositions of the actual state of the science, in which enthusiasm for what is new is tempered by a due respect for what is old, and in which new and old are brought into harmonious relation with each other, these treatises stand almost unrivalled. Whether in the originals, or in the guise of translations, they are accounted as classics in every university of the world. So far as British universities are concerned, they have formed the starting point of a whole series of works conceived in a similar spirit, though naturally not always crowned by the same success. The necessity for this kind of work grows, indeed, continually; the modern fragmentary fashion of original publication and the numerous channels through which it takes place make it difficult for anyone to become initiated into a new scientific theory unless he takes it up at the very beginning and follows it diligently throughout its course, backwards and forwards, over rough ground and smooth. The classical style of memoir, after the manner of Lagrange, or Poisson, or Gauss, complete in itself and deliberately composed like a work of art, is continually becoming rarer. It is, therefore, more and more essential that from time someone should come forward to sort out and arrange the accumulated material, rejecting what has proved unimportant, and welding the rest into a connected system. There is perhaps a tendency to assume that such work is of secondary importance, and can be safely left to subordinate hands. But in reality it makes severe demands on even the highest powers; and when these have been available the result has often done more for the progress of science than the composition of a dozen monographs on isolated points. For proof one need only point to the treatises of Salmon himself, or recall (in another field) the debt which we owe to such books as the "Treatise on Natural Philosophy" and the "Theory of Sound," whose authors are happily with us.

A modest but most valuable worker has passed away in the person of Prof. Allman. His treatise on the history of Greek geometry, full of learning and sound mathematical perception, is written with great simplicity and an entire absence of pedantry or dogmatism. It ranks, I believe, with the best that has been done in the subject. It is to be regretted that, as an historian, he leaves so few successors among British mathematicians. We have amongst us, as a result of our system of university education, many men of trained mathematical faculty and of a scholarly turn of mind, with much of the necessary linguistic equipment, who feel, however, no special vocation for the details of recent mathematical research. Might not some of this ability be turned to a field, by no means exhausted, where the severity of mathematical truth is tempered by the human interest attaching to the lives, the vicissitudes, and even the passions and the strife of its devotees, who through many errors and perplexities have contrived to keep alive and trim the sacred flame, and to hand it on burning ever clearer and brighter?

Of the various subjects which fall within the scope of this section there is no difficulty in naming that which at the present time excites the widest interest. The phenomena of radioactivity, ionisation of gases, and so on, are not only startling and sensational in themselves, they have suggested most wonderful and far-reaching speculations, and, whatever be the future of these particular theories, they are bound in any case deeply to influence our views on fundamental points of chemistry and physics. No reference to this subject would, I think, be satisfactory without a word of homage to the unsurpassed patience and skill in the devising of new experimental methods to meet new and subtle conditions which it has evoked. It will be felt as a matter of legitimate pride by many present that the University of Cambridge has been so conspicuously associated with this work. It would, therefore, have been natural and appropriate that this chair should have been occupied, this year above others, by one who could have given us a survey of the facts as they at present stand, and of their bearing, so far as can be discerned, on other and older branches of physics. Whether from the experimental or from the more theoretical and philosophical standpoint, there would have been no difficulty in finding exponents of unrivalled authority. But it has been otherwise ordered, and you and I must make the best of it. If the subject cannot be further dealt with for the moment, we have the satisfaction of knowing that it will, in due course, engage the attention of the section, and that we may look forward to interesting and stimulating discussions, in which we trust the many distinguished foreign physicists who honour us by their presence will take an active part.

It is, I believe, not an unknown thing for your president to look up the records of previous meetings in search of inspiration, and possibly of an example. I have myself not had to look very far, for I found that when the British Association last met in Cambridge, in the year 1862, this section was presided over by Stokes, and, moreover, that the address which he gave was probably the shortest ever made on such an occasion, for it occupies only half a page of the report, and took, I should say, some three or four minutes to deliver. It would be to the advantage of the business of the meeting, and to my own great relief, if I had the courage to follow so attractive a precedent; but I fear that the tradition which has since established itself is too strong for me to break without presumption. I will turn, therefore, in the first instance, to a theme which, I think, naturally presents itself—viz., a consideration of the place occupied by Stokes in the development of mathematical physics. It is not proposed to attempt an examination or appreciation of his own individual achievements; this has lately been done by more than one hand, and in the most authoritative manner. But it is part of the greatness of the man that his work can be reviewed from more than one standpoint. What I specially wish to direct attention to on this occasion is the historical or evolutionary relation in which he stands to predecessors and followers in the above field.

The early years of Stokes's life were the closing years of a mighty generation of mathematicians and mathematical physicists. When he came to manhood, Lagrange, Laplace, Poisson, Fourier, Fresnel, Ampère, had but recently passed away. Cauchy alone of this race of giants was still alive and productive. It is upon these men that we must look as the immediate intellectual ancestors of Stokes, for, although Gauss and F. Neumann were alive and flourishing, the interaction of German and English science was at that time not very great. It is noteworthy, however, that the development of the modern German school of mathematical physics, represented by Helmholtz and Kirchhoff in linear succession to Neumann, ran in many respects closely parallel to the work of Stokes and his followers.

When the foundations of analytical dynamics had been laid by Euler and d'Alembert, the first important application was naturally to the problems of gravitational astronomy. This formed, of course, the chief work of Laplace, Lagrange, and others. Afterwards came the theoretical study of elasticity, conduction of heat, statical electricity, and magnetism. The investigations in elasticity were undertaken mainly in relation to physical optics, with the hope of finding a material medium capable of conveying transverse vibrations, and of accounting also for the various phenomena of reflection, refraction, and double refraction. It has often been pointed out, as characteristic of the French school referred to, that their physical speculations were largely influenced by ideas transferred from astronomy—as, for

Digitized by Google

instance, in the conception of a solid body as made up of discrete particles acting on one another at a distance with forces in the lines joining them, which formed the basis of most of their work on elasticity and optics. The difficulty of carrying out these ideas in a logical manner were enormous, and the strict course of mathematical deduction had to be replaced by more or less precarious assumptions. The detailed study of the geometry of a continuous deformable medium which was instituted by Cauchy, was a first step towards liberating the theory from arbitrary and unnecessary hypothesis; but it was reserved for Green, the immediate predecessor of Stokes among English mathematicians, to carry out this process completely and independently, with the help of Lagrange's general dynamical methods, which here found their first application to questions of physics outside the ordinary dynamics of rigid bodies and fluids. The modern school of English physicists, since the time of Green and Stokes, have consistently endeavoured to make out, in any given class of phenomena, how much can be recognised as a manifestation of general dynamical principles, independent of the particular mechanism which may be at work. One of the most striking examples of this was the identification by Maxwell of the laws of electromagnetism with the dynamical equations of Lagrange. It would, however, be going too far to claim this tendency as the exclusive characteristic of English physicists. For example, the elastic investigations of Green and Stokes have their parallel in the independent though later work of Kirchhoff; and the beautiful theory of dynamical systems with latent motion which we owe to Lord Kelvin stands in a very similar relation to the work of Helmholtz and Hertz.

But perhaps the most important and characteristic feature in the mathematical work of the later school is its increasing relation to and association with experiment. In the days when the chief applications of mathematics were to the problems of gravitational astronomy, the mathematician might well take his materials at second hand; and in some respects the division of labour was, and still may be, of advantage. The same thing holds in a measure of the problems of ordinary dynamics, where some practical knowledge of the subject-matter is within the reach of everyone. But when we pass to the more recondite phenomena of physical optics, acoustics, and electricity, it hardly needs the demonstrations which have involuntarily been given to show that the theoretical treatment must tend to degenerate into the pursuit of mere academic subtleties unless it is constantly vivified by direct contact with reality. Stokes, at all events, with little guidance or encouragement from his immediate environment, made himself from the first practically acquainted with the subjects he treated. Generations of Cambridge students recall the enthusiasm which characterised his experimental demonstrations in optics. These appealed to us all, but some of us, I am afraid, under the influence of the academic ideas of the time, thought it a little unnecessary to show practically that the height of the lecture-room could be measured by the barometer, or to verify the calculated period of oscillation of water in a tank by actually timing the waves with the help of the image of a candle-flame reflected at the surface.

The practical character of the mathematical work of Stokes and his followers is shown especially in the constant effort to reduce the solution of a physical problem to a quantitative form. A conspicuous instance is furnished by the labour and skill which he devoted from this point of view to the theory of the Bessel's function, which presents itself so frequently in important questions of optics, electricity, and acoustics, but is so refractory to ordinary methods of treatment. It is now generally accepted that an analytical solution of a physical question, however elegant it may be made to appear by means of a judicious notation, is not complete so long as the results are given merely in terms of functions defined by infinite series or definite integrals, and cannot be exhibited in a numerical or graphical form. This view did not originate, of course, with Stokes; it is clearly indicated, for instance, in the works of Fourier and Poinsot, but no previous writer had, I think, acted upon it so consistently and thoroughly.

We have had so many striking examples of the fruitfulness of the combination of great mathematical and experimental powers that the question may well be raised, whether there is any longer a reason for maintaining in our minds a distinction between mathematical and experimental physics, or at all events whether these should be looked upon as separate provinces which may conveniently be assigned to different sets of labourers. It may be held that the highest physical research will demand in the future the possession of both kinds of faculty. We must be careful, however, how we erect barriers which would exclude a Lagrange on the one side or a Faraday on the other. There are many mansions in the palace of physical science, and work for various types of mind. A zealous, or over-zealous, mathematician might indeed make out something of a case if he were to contend that, after all, the greatest work of such men as Stokes, Kirchhoff, and Maxwell was mathematical rather than experimental in its complexion. An argument which asks us to leave out of account such things as the investigation of fluorescence, the discovery of spectrum analysis, and the measurement of the viscosity of gases, may seem audacious; but a survey of the collected works of these writers will show how much, of the very highest quality and import would remain. However this may be, the essential point, which cannot, I think, be contested, is this, that if these men had been condemned and restricted to a mere book knowledge of the subjects which they have treated with such marvellous analytical ability, the very soul of their work would have been taken away. I have ventured to dwell upon this point because, although I am myself disposed to plead for the continued recognition of mathematical physics as a fairly separate field, I feel strongly that the traditional kind of education given to our professed mathematical students does not tend to its most effectual cultivation. This education is apt to be one-sided, and too much divorced from the study of tangible things. Even the student whose tastes lie mainly in the direction of pure mathematics would profit, I think, by a wider scientific training. A long list of instances might be given to show that the most fruitful ideas in pure mathematics have been suggested by the study of physical problems. In the words of Fourier, who did so much to fulfil his own saying, "L'étude approfondie de la nature est la source la plus féconde des découvertes mathématiques. Non-seulement cette étude, en offrant aux recherches un but déterminé, a l'avantage d'exclure les questions vagues et les calculs sans issue; elle est encore un moyen assuré de former l'analyse elle-même, et d'en découvrir les éléments qu'il nous importe le plus de connaître, et que cette science doit toujours conserver: ces éléments fondamentaux sont ceux qui se reproduisent dans tous les effets naturels."

Another characteristic of the applied mathematics of the past century is that it was, on the whole, the age of linear equations. The analytical armoury fashioned by Lagrange, Poisson, Fourier, and others, though subject, of course, to continual improvement and development, has served the turn of a long line of successors. The predominance of linear equations, in most of the physical subjects referred to, rests on the fact that the changes are treated as infinitely small. The electric theory of light forms at present an exception, but even here the linear character of the fundamental electrical relations is itself remarkable, and possibly significant. The theory of small oscillations, in particular, runs as a thread through a great part of the literature of the period in question. It has suggested many important analytical results, and it still gives the best and simplest intuitive foundation for a whole class of theorems which are otherwise hard to comprehend in their various relations, such as Fourier's theorem, Laplace's expansion, Bessel's functions, and the like. Moreover, the interest of the subject, whether mathematical or physical, is not yet exhausted; many important problems in optics and acoustics, for example, still await solution. The general theory has, in comparatively recent times, received an unexpected extension (to the case of "latent motions") at the hands of Lord Kelvin; and Lord Rayleigh, by his continual additions to it, shows that, in his view, it is still incomplete.

When the restriction to infinitely small motions is abandoned, the problems become, of course, much more arduous

Digitized by Google

The whole theory, for instance, of the normal modes of vibration which is so important in acoustics, and even in music disappears. The researches hitherto made in this direction have, moreover, encountered difficulties of a less patent character. It is conceivable that the modern analytical methods which have been developed in astronomy may have an application to these questions. It would appear that there is an opening here for the mathematician; at all events, the numerical or graphical solution of any one of the various problems that could be suggested would be of the highest interest. One problem of the kind is already classical—the theory of steep water-waves discussed by Stokes; but even here the point of view has perhaps been rather artificially restricted. The question proposed by him, the determination of the possible form of waves of permanent type, like the problem of periodic orbits in astronomy, is very interesting mathematically, and forms a natural starting point for investigation; but it does not exhaust what is most important for us to know in the matter. Observation may suggest the existence of such waves as a fact; but no reason has been given, so far as I know, why free water-waves should tend to assume a form consistent with permanence, or be influenced in their progress by considerations of geometrical simplicity.

I have tried to indicate the kind of continuity of subject-matter, method, and spirit which runs through the work of the whole school of mathematical physicists, of which Stokes may be taken as the representative. It is no less interesting, I think, to examine the points of contrast with more recent tendencies. These relate not so much to subject-matter and method as to the general mental attitude towards the problems of Nature. Mathematical and physical science have become markedly introspective. The investigators of the classical school, as it may perhaps be styled, were animated by a simple and vigorous faith; they sought as a matter of course for a mechanical explanation of phenomena, and had no misgivings as to the trustiness of the analytical weapons which they wielded. But now the physicist and the mathematician alike are in trouble about their souls. We have discussions on the principles of mechanics, on the foundations of geometry, on the logic of the most rudimentary arithmetical processes, as well as of the more artificial operations of the calculus. These discussions are legitimate and inevitable, and have led to some results which are now widely accepted. Although they were carried on to a great extent independently, the questions involved will, I think, be found to be ultimately very closely connected. Their common nexus is, perhaps, to be traced in the physiological ideas of which Helmholtz was the most conspicuous exponent. To many minds such discussions are repellent, in that they seem to venture on the uncertain ground of philosophy. But, as a matter of fact, the current views on these subjects have been arrived at by men who have gone to work in their own way, often in entire ignorance of what philosophers have thought on such subjects. It may be maintained chiefly, indeed, that the mathematician or the physicist, as such, has no special concern with philosophy, any more than the engineer or the geographer. Nor, although this is a matter for their own judgment, would it appear that philosophers have very much to gain by a special study of the methods of mathematical or physical reasoning, since the problems with which they are concerned are presented to them in a much less artificial form in the circumstances of ordinary life. As regards the present topic I would put the matter in this way: that between mathematics and physics on the one hand and philosophy on the other there lies an undefined borderland, and that the mathematician has been engaged in setting things in order, as he is entitled to do, on his own side of the boundary.

Adopting this point of view, it would be of interest to trace in detail the relationships of the three currents of speculation which have been referred to. At one time, indeed, I was tempted to take this as the subject of my address; but, although I still think the enterprise a possible one, I have been forced to recognise that it demands a better equipment than I can pretend to. I can only venture to put before you some of my tangled thoughts on the matter, trusting that some future occupant of this chair may be induced to take up the question and treat it in a more illuminating manner.

If we look back for a moment to the views currently entertained not so very long ago by mathematicians and physicists, we shall find, I think, that the prevalent conception of the world was that it was constructed on some sort of absolute geometrical plan, and that the changes in it proceeded according to precise laws; that, although the principles of mechanics might be imperfectly stated in our text-books, at all events such principles existed, and were ascertainable, and, when properly formulated, would possess the definiteness and precision which were held to characterise, say, the postulates of Euclid. Some writers have maintained, indeed, that the principles in question were finally laid down by Newton, and have occasionally used language which suggests that any fuller understanding of them was a mere matter of interpretation of the text. But, as Hertz has remarked, most of the great writers on dynamics betray, involuntarily, a certain *malaise* when explaining the principles, and hurry over this part of their task as quickly as is consistent with dignity. They are not really at their ease until, having established their equations somehow, they can proceed to build securely on these. This has led some people to the view that the laws of Nature are merely a system of differential equations. It may be remarked in passing that this is very much the position in which we actually stand in some of the more recent theories of electricity. As regards dynamics, when once the critical movement had set in, it was easy to show that one presentation after another was logically defective and confused, and no satisfactory standpoint was reached until it was recognised that in the classical dynamics we do not deal immediately with real bodies at all, but with certain conventional and highly idealised representations of them, which we combine according to arbitrary rules, in the hope that if these rules be judiciously framed the varying combinations will image to us what is of most interest in some of the simpler and more important phenomena. The changed point of view is often associated with the publication of Kirchhoff's lectures on mechanics in 1876, where it is laid down in the opening sentence that the problem of mechanics is to describe the motions which occur in Nature completely and in the simplest manner. This statement must not be taken too literally; at all events, a fuller, and I think a clearer, account of the province and the method of abstract dynamics is given in a review of the second edition of Thomson and Tait, which was one of the last things penned by Maxwell, in 1879. A "complete" description of even the simplest natural phenomenon is an obvious impossibility; and, were it possible, it would be uninteresting as well as useless, for it would take an incalculable time to peruse. Some process of selection and idealisation is inevitable if we are to gain any intelligent comprehension of events. Thus, in astronomy we replace a planet by a so-called material particle — *i.e.*, a mathematical point associated with a suitable numerical coefficient. All the properties of the body are here ignored except those of position and mass, in which alone we are at the moment interested. The whole course of physical sciences and the language in which its results are expressed have been largely determined by the fact that the ideal images of geometry were already at hand at its service. The ideal representations have the advantage that, unlike the real objects, definite and accurate statements can be made about them. Thus two lines in a geometrical figure can be pronounced to be equal or unequal, and the statement is in either case absolute. It is no doubt hard to divest oneself entirely of the notion conveyed in the Greek phrase, ἀεὶ ὁ θεὸς γεωμετρεῖ, that definite geometrical magnitudes and relations are at the back of phenomena. It is recognised, indeed, that all our measurements are necessarily to some degree uncertain, but this is usually attributed to our own limitations and those of our instruments rather than to the ultimate vagueness of the entity which it is sought to measure. Everyone will grant, however, that the distance between two clouds, for instance, is not a definable magnitude; and the distance of the earth from the sun, and even the length of a wave of light, are in precisely the same case. The notion in question is a convenient fiction, and

Digitized by Google

is a striking testimony to the ascendancy which Greek mathematics have gained over our minds, but I do not think that more can be said for it. It is, at any rate, not verified by the experience of those who actually undertake physical measurements. The more refined the means employed, the more vague and elusive does the supposed magnitude become; the judgment flickers and wavers, until at last in a sort of despair *some* result is put down, not in the belief that it is exact, but with the feeling that it is the best we can make of the matter. A practical measurement is, in fact, a classification; we assign a magnitude to a certain category, which may be narrowly limited, but which has in any case a certain breadth.

By a frank process of idealisation a logical system of abstract dynamics can doubtless be built up, on the lines sketched by Maxwell in the passage referred to. Such difficulties as remain are handed over to geometry. But we cannot stop in this position; we are constrained to examine the nature and the origin of the conceptions of geometry itself. By many of us, I imagine, the first suggestion that these conceptions are to be traced to an empirical source was received with something of indignation and scorn; it was an outrage on the science which we had been led to look upon as divine. Most of us have, however, been forced at length to acquiesce in the view that geometry, like mechanics, is an applied science; that it gives us merely an ingenious and convenient symbolic representation of the relations of actual bodies; and that, whatever may be the *a priori* forms of intuition, the science as we have it could never have been developed except for the accident (if I may so term it) that we live in a world in which rigid or approximately rigid bodies are conspicuous objects. On this view the most refined geometrical demonstration can be resolved into a series of imagined experiments performed with such bodies, or rather with their conventional representations.

It is to be lamented that one of the most interesting chapters in the history of science is a blank: I mean that which would have unfolded the rise and growth of our system of ideal geometry. The finished edifice is before us, but the record of the efforts by which the various stones were fitted into their places is hopelessly lost. The few fragments of professed history which we possess were edited long after the achievement.

It is commonly reckoned that the first rude beginnings of geometry date from the Egyptians. I am inclined to think that in one sense the matter is to be placed much further back, and that the dawn of geometric ideas is to be traced among the prehistoric races who carved rough but thoroughly artistic outlines of animals on their weapons. I do not know whether the matter has attracted serious speculation, but I have myself been led to wonder how men first arrived at the notion of an outline drawing. The primitive sketches referred to immediately convey to the experienced mind the idea of a reindeer or the like; but in reality the representation is purely conventional, and is expressed in a language which has to be learned. For nothing could be more unlike the actual reindeer than the few scratches drawn on the surface of a bone: and it is, of course, familiar to ourselves that it is only after a time, and by an insensible process of education, that very young children come to understand the meaning of an outline. Whoever he was, the man who first projected the world into two dimensions, and proceeded to fence off that part of it which was reindeer from that which was not, was certainly under the influence of a geometrical idea, and had his feet in the path which was to culminate in the refined idealisations of the Greeks. As to the manner in which these latter were developed, the only indication of tradition is that some propositions were arrived at first in a more empirical or intuitional, and afterwards in a more intellectual way. So long as points had size, lines had breadth, and surfaces thickness, there could be no question of exact relations between the various elements of a figure, any more than is the case with the realities which they represent. But the Greek mind loved definiteness, and discovered that if we agree to speak of lines *as if* they had no breadth, and so on, exact statements became possible. If any one scientific invention can claim pre-eminence over all others, I should be inclined myself to erect a monument to the inventor of the mathematical point, as the supreme type of that process of abstraction which has been a necessary condition of scientific work from the very beginning.

It is possible, however, to uphold the importance of the part which abstract geometry has played, and must still play, in the evolution of scientific conceptions, without committing ourselves to a defence, on all points, of the traditional presentment. The consistency and completeness of the usual system of definitions, axioms, and postulates has often been questioned, and quite recently a more thorough-going analysis of the logical elements of the subject than has ever before been attempted has been made by Hilbert. The matter is a subtle one, and a general agreement on such points is as yet hardly possible. The basis for such an agreement may perhaps ultimately be found in a more explicit recognition of the empirical source of the fundamental conceptions. This would tend, at all events, to mitigate the rigour of the demands which are sometimes made for logical perfection.

Even more important in some respects are the questions which have arisen in connection with the application of geometry to purposes of graphical representation. It is not necessary to dwell on the great assistance which this method has rendered in such subjects as physics and engineering. The pure mathematician, for his part, will freely testify to the influence which it has exercised in the development of most branches of analysis—for example, we owe to it all the leading ideas of the calculus. Modern analysts have discovered, however, that geometry may be a snare as well as a guide. In the mere act of drawing a curve to represent an analytical function, we make unconsciously a host of assumptions which are difficult not merely to prove, but even to formulate precisely. It is now sought to establish the whole fabric of mathematical analysis on a strictly arithmetical basis. To those who were trained in an earlier school, the results so far are in appearance somewhat forbidding. If the shade of one of the great analysts of a century ago could revisit the glimpses of the moon, his feelings would, I think, be akin to those of the traveller to some mediæval town, who finds the buildings he came to see obscured by scaffolding, and is told that the ancient monuments are all in process of repair. It is to be hoped that a good deal of this obstruction is only temporary, that most of the scaffolding will eventually be cleared away, and that the edifices when they reappear will not be entirely transformed, but will still retain something of their historic outlines. It would be contrary to the spirit of this address to undertake in any way the critical examination and revision of principles; we must acknowledge that it tends ultimately to simplification, to the clearing up of issues, and the reconciliation of apparent contradictions. But it would be a misfortune if this process were to absorb too large a share of the attention of mathematicians, or were allowed to set too high a standard of logical completeness. In this particular matter of the "arithmetisation of mathematics" there is, I think, a danger in these respects. As regards the latter point, a traveller who refuses to pass over a bridge until he has personally tested the soundness of every part of it is not likely to go very far; something must be risked, even in mathematics. It is notorious that even in this realm of "exact" thought discovery has often been in advance of strict logic, as in the theory of imaginaries, for example, and in the whole province of analysis of which Fourier's theorem is the type. And it might even be claimed that the services which geometry has rendered to other sciences have been almost as great in virtue of the questions which it implicitly begs as of those which it resolves.

I would venture, with some trepidation, to go one step further. Mathematicians love to build on as definite a foundation as possible, and from this point of view the notion of the integral number, on which (we are told) the mathematics of the future are to be based, is very attractive. But as an instrument for the study of Nature, is it really more fundamental than the geometrical notions which it is to supersede? The accounts of primitive peoples would seem to show that, in the generality which is a

Digitized by Google

necessary condition for this purpose, it is in no less degree artificial and acquired. Moreover, does not the act of enumeration, as supplied to actual things, involve the very same process of selection and idealisation which we have already met with in other cases? As an illustration, suppose we were to try to count the number of drops of water in a cloud.*

I am not thinking of the mere practical difficulties of enumeration, or even of the more pertinent fact that it is hard to say where the cloud begins or ends. Waiving these points, it is obvious that there must be transitional stages between a more or less dense group of molecules and a drop, and in the case of some of these aggregates it would only be by an arbitrary exercise of judgment that they would be assigned to one category rather than to the other. In whatever form we meet with it the very notion of counting involves the highly artificial conception of a number of objects which for some purposes are treated as absolutely alike, whilst yet they can be distinguished.

The net result of the preceding survey is that the systems of geometry, of mechanics, and even of arithmetic, on which we base our study of Nature, are all contrivances of the same general kind: they consist of series of abstractions and conventions devised to represent, or rather to symbolise, what is most interesting and most accessible to us in the world of phenomena And the progress of science consists, in a great measure, in the improvement, the development, and the simplification of these artificial conceptions, so that their scope may be wider and the representation more complete. The best in this kind are but shadows, but we may continually do something to amend them.

As compared with the older view, the function of physical science is seen to be much more modest than was at one time supposed. We no longer hope by levers and screws to pluck out the heart of the mystery of the universe. But there are compensations. The conception of the physical world as a mechanism, constructed on a rigid mathematical plan, whose most intimate details might possibly some day be guessed, was, I think, somewhat depressing. We have been led to recognise that the formal and mathematical element is of our own introduction; that it is merely the apparatus by which we map out our knowledge, and has no more objective reality than the circles of latitude and longitude on the sun. A distinguished writer not very long ago speculated on the possibility of the scientific mine being worked out within no distant period. Recent discoveries seem to have put back this possibility indefinitely; and the tendency of modern speculation as to the nature of scientific knowledge should be to banish it altogether. The world remains a more wonderful place than ever; we may be sure that it abounds in riches not yet dreamed of; and although we cannot hope ever to explore its innermost recesses, we may be confident that it will supply tasks in abundance for the scientific mind for ages to come.

One significant result of the modern tendency is that we no longer with the same obstinacy demand a mechanical explanation of the phenomena of light and electricity, especially since it has been made clear that if one mechanical explanation is possible there will be an infinity of others Some minds, indeed, revelling in their new-found freedom, have attempted to disestablish ordinary or "vulgar" matter altogether. I may refer to a certain treatise, which by some accident does not bear its proper title of "Ether and *no* Matter," and to the elaborate investigations of Prof. Osborne Reynolds, which present the same peculiarity, although the basis is different. Speculations of this nature have, however, been so recently and (if I may say it) so brilliantly dealt with by Prof. Poynting before this section that there is little excuse for dwelling further on them now. I will only advert to the question whether, as some suggest, physical science should definitely abandon the attempt to construct mechanical theories in the older sense. The question would appear to be very similar to this, whether we should abandon the use of graphical methods in analysis. In either case we run the risk of introducing extraneous elements, possibly of a misleading character; but the gain in vividness of perception and in suggestiveness is so great that we are not likely altogether to forego it, by excess of prudence, in one case more than in the other.

We have travelled some distance from Stokes and the mathematical physics of half a century ago. May I add a few observations which might perhaps have claimed his sympathy? They are in substance anything but new, although I do not find them easy to express. We have most of us frankly adopted the empirical attitude in physical science; it has justified itself abundantly in the past, and has more and more forced itself upon us. We have given up the notion of causation, except as a convenient phrase; what were once called laws of Nature are now simply rules by which we can tell more or less accurately what will be the consequence of a given state of things. We cannot help asking, How is it that such rules are possible? A rule is invented in the first instance to sum up in a compact form a number of past experiences, but we apply it, with little hesitation, and generally with success, to the prediction of new and sometimes strange ones. Thus the law of gravitation indicates the existence of Neptune, and Fresnel's wave-surface gives us the quite unsuspected phenomenon of double refraction. Why does Nature make a point of honouring our cheques in this manner; or, to put the matter in a more dignified form, how comes it that, in the words of Schiller,*

> "Mit dem Genius steht die Natur im ewigen Bunde,
> Was der eine verspricht, leistet die andre gewiss"?

The question is as old as science, and the modern tendencies with which we have been occupied have only added point to it. It is plain that physical science has no answer; its policy, indeed, has been to retreat from a territory which it could not securely occupy. We are told in some quarters that it is vain to look for an answer anywhere. But the mind of man is not wholly given over to physical science, and will not be content for ever to leave the question alone. It will persist in its obstinate questionings, and however hopeless the attempt to unravel the mystery may be deemed, physical science, powerless to assist, has no right to condemn it.

I would like, in conclusion, to read to you a characteristic passage from that address of Stokes in 1862 which has formed the starting point of this discourse:

"In this section, more perhaps than in any other, we have frequently to deal with subjects of a very abstract character, which in many cases can be mastered only by patient study, at leisure, of what has been written. The question may not unnaturally be asked, If investigations of this kind can best be followed by quiet study in one's own room, what is the use of bringing them forward in a sectional meeting at all? I believe that good may be done by public mention, in a meeting like the present, of even somewhat abstract investigations; but whether good is thus done, or the audience merely wearied to no purpose, depends upon the judiciousness of the person by whom the investigation is brought forward."

It might be urged that these remarks are as pertinent now as they were 40 years ago, but I will leave them on their own weighty authority. I will not myself attempt to emphasise them, lest some of my hearers should be tempted to retort that the warning might well be borne in mind not only in the ordinary proceedings of the section, but in the composition of a presidential address!

The Electrolytic Production of Water-Jackets on Automobile Engines.—*L'Industrie Electrique* describes a novel method employed by Messrs. Napier for keeping down the over-all dimensions and the weights of their engines to a minimum. The water-jackets of these engines are made of thin copper deposited in position electrolytically. The outside of the cylinder is given a coating usually of a mixture of wax and plumbago of just the thickness of the space required for the water to circulate in. Those parts of the cylinder to which the water-jacket is to adhere are left bare, and the whole cylinder is then put into the electrolytic bath, and a uniform coating of the required thickness is deposited. The whole is then heated to melt out the wax, and the operation is complete. The same method should prove serviceable in many other cases.

* Applied by Herschel to the discovery of Neptune.

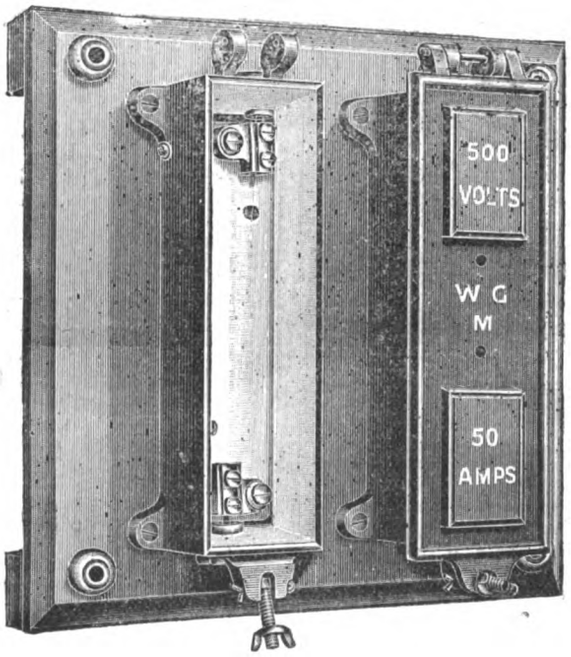
TRADE NOTICES AND NOVELTIES.

G.E.C. Specialities.

The progress sheet issued by the General Electric Company, Limited, 71, Queen Victoria-street, E.C., for August illustrates a new type of "Stanley" measuring instrument, known as the "Aperiodic," which has been designed to suit the requirements where absolutely dead-beat instruments are a necessity. It is claimed that on fluctuating loads readings may be made with this instrument with the strictest accuracy. All ammeters and voltmeters of the new type are ruby jewelled and calibrated throughout their range by direct comparison with standards. We also note that another addition has been made to the firm's extensive list of "Freezor" fans. This is a portable fan, which is being supplied in two sizes—viz., 12in. and 16in., with a current consumption of 55 and 110 watts respectively. A form of "Quadrant" tumbler switch is illustrated with a detachable key or lever, and an announcement appears that the company are now making oval tube "Union" conduit, in three sizes, both close joint and brazed, prices being given.

"Vitro" Fuse Boxes.

We illustrate herewith a new type of fuse box, known as the "Vitro," which is being introduced by Messrs. Ward and Goldstone, Dutton-street, Strangeways, Manchester. "Vitro" fuse boxes are enamelled inside with vitreous glass enamel, applied to the iron at an intense heat, and which covers the iron with a surface similar to white porcelain, and of equal insulating properties to that of china. It is claimed that this lining stands heat and compression much better than asbestos, which latter is unsatisfactory owing to its retention of damp and a tendency to buckle, also that the insulating properties of asbestos are very poor compared with vitreous enamelling.



With reference to these claims, it is stated that the enamelling will withstand the heat and compression which occurs on a dead short-circuit of heavy current on high voltages.

Miniature Arc Lamps.

The Union Electric Company, Limited, 151, Queen Victoria-street, E.C., are issuing a new list of their miniature arc lamps to the trade. Attention is called to a few more important features of these lamps. They embody all the well-known good qualities of the firm's larger arc lamps, the mechanism alone being carried out on a smaller scale. The working parts, all of which are interchangeable, are surrounded by a durable bronze metal protecting cover, which maintains its handsome appearance even in the most trying atmospheres for a long period. It is claimed that these lamps are unique in their long-burning qualities, 22 hours of burning being obtained with satisfactory and economical working while using small-size carbons. Special finishes have been designed to adapt the lamps for many classes of interior and exterior illumination.

Car-Lighting Resistances.

The A.E.G. English Manufacturing Company, Limited, 4, New Compton-street, Charing Cross-road, W.C., have sent us some particulars of their car-lighting resistances. In these resistances use is made of the high temperature coefficient of iron, which makes it possible to keep the current constant within a certain range of voltages. They are made for four currents: 0·4, 0·8, 1, and 1·2 amperes. The following example will explain their working. Several trains on the Prussian State railways are equipped with the system. A battery of 30 cells is charged from a dynamo on the locomotive. No accumulator switches are employed, the regulating of the pressure being done by the car-lighting resistances only, of which there is one to every incandescent lamp. The highest pressure obtained is $30 \times 2{\cdot}5 = 75$ volts; the lowest $30 \times 1{\cdot}85 = 55$ volts. The resistances, therefore, have to regulate between 55 and $75 - i.e.$, 20 volts. They, however, do not regulate from 0 to 20 volts, but from 10 to 30 volts, or generally, if the difference of pressure (in the above case 20 volts) is called x, from $\frac{x}{2}$ to $\frac{3x}{2}$. In the above-mentioned case 45-volt lamps have to be used, so that at the lowest $(45+10=55$ volts) as well as at the highest pressure $(45+30=75$ volts), the resistance remains inside its range of regulating capacity. The variation of current these car-lighting resistances are subject to does not exceed 4 per cent. either way—*i.e.*, a 1-ampere 20-volt resistance will, at 10 volts, not take less than 0·96, and at 30 volts not more than 1·04 amperes. For tramways these resistances have also been used with great success. In a case like this, where the voltage varies from 450 to 550 volts, the resistances regulate from 50 to 150 volts. Four incandescent lamps of 100 volts were therefore used in series. The tramway resistances are made for 0·4 ampere only. The life of the car-lighting resistances is, under normal conditions, several thousand hours. They are constructed on similar principles to the firm's Nernst lamp resistances. To avoid mistakes, the different size resistances are supplied with different caps.

Show Card.

The Simplex Steel Conduit Company, Limited, Westinghouse-building, Norfolk-street, Strand, W.C., are issuing a flexible trade show card illustrating the majority of the fittings supplied by them, together with a sample of their tubing, giving an idea of the style and finish of the same. This card should prove of use to the firm's customers for reference purposes.

STOCKTON-ON-TEES ELECTRICITY ACCOUNTS.

We give herewith abstracts of the revenue account and general balance sheet for the year ended March 31, 1904, as issued by the Stockton-on-Tees electricity department.

REVENUE ACCOUNT.

Dr. Expenditure.	£	s.	d.
Generation of electricity	1,831	13	7
Distribution of electricity	202	9	8
Building repairs	24	10	6

NEW COMPANIES REGISTERED.

Elsworth Automobile Company, Limited.—Capital, £10,000. Objects: to acquire the business carried on by A. Elsworth at Dudley Hill and 28, Manningham-lane, both in Bradford; to adopt an agreement between A. Elsworth and G. E. Levie; and to carry on the business of manufacturers of and dealers in motorcars, motor cycles, and motor vehicles and lorries of all kinds.

Lien Registered.

Fleetwood and District Electric Light and Power Syndicate, Limited.—A charge, dated Aug. 16, 1904, to secure £500, and further advances up to £700 (created under authority of the High Court by W. Cash, the receiver appointed by the Court), has been registered. Property charged: all the company's undertaking and assets (in priority to trust deed dated Oct. 1, 1899, and certain subsequent debentures created or issued thereunder). Holder: W. C. Johnson, 32, Hyde Park-gardens, London.

LEGAL INTELLIGENCE.

CAR OBSTRUCTION.

Thos. Frederick Hazeldine appeared at Brighton Police Court on Tuesday on a charge of obstructing a Corporation tramcar in Dyke-road on August Bank Holiday.

Mr. Hugh Talbot (town clerk) appeared to prosecute, and Mr. J. Percival Hughes, barrister, instructed by Mr. H. E. Trangmar, represented the defendant.

The **Motorman** deposed that just as his car reached the stopping place opposite the Dyke-road Hotel the char-a-banc driven by the defendant started, and, crossing the line behind the car, got on the track in front and drove up Dyke-road. When witness restarted defendant was about 12 yards ahead of the tramcar, and witness accordingly sounded his gong. Defendant took no notice, however, although witness sounded the gong repeatedly, and continued on the track in front of the car until the end of the journey, delaying the car three minutes. There was no traffic to prevent the defendant pulling to the offside and letting the car pass.

Cross-examined by Mr. Hughes, witness denied that he was behind time. He could not say with certainty that the car would have cleared the char-a-banc if defendant had pulled to the near side. Unless defendant had gone to the offside he was not certain he could have cleared him at any point of the route.

The **Conductor**, in giving corroborative evidence, admitted that there was a good deal of traffic about.

Frederick Noel Hudson, assistant surveyor in the tramways department, produced a plan of the route, showing the trees on each side of the road, and gave evidence with the object of showing that there was room for defendant to have pulled to one side and let the car pass.

Defendant deposed that, except at certain points, the trees on the near side of the road would have stopped him pulling to the near side, and it was not possible without danger to pull to the off side, owing to the traffic. He made his horses travel faster so as not to delay the car, and when he came to a place where he could pull in to the near side, he stopped and did so; but the car also stepped and so witness drove on. He did not at any point wilfully obstruct the car. He had orders not to pull to the off side, as it was dangerous.

The **Driver** of the mail coach from London to Brighton said he had driven the char-a-banc in question up the Dyke-road, and found it was not safe to do anything but keep going, and that to pull to the off side would be dangerous, while the trees interfered with pulling to the near side.

Mr. Hughes, for the defence, contended that there was nothing wilful on the part of the defendant, who had a perfect right to use the road fairly and reasonably. An important principle was involved, which it might be necessary for even a higher court to consider—viz., as to whether a tramcar had the right to so monopolise the use of the road so that other vehicles, who had an equal, if not greater, certainly a prior use to the road, should get out of the way.

The Bench retired to consider the case, and, on returning, the **Chairman** said the conclusion they had arrived at was that there had been an obstruction, and that it was wilful. Defendant would be fined 10s. and costs, or 14 days in default.

The **Magistrates** refused to state a case, as they had decided on the facts adduced.

Mr. Hughes intimated his intention of appealing.

RECKLESS MOTORMAN.

At Aberdeen Police Court Robert Quirie was fined 20s. for driving an electric car carelessly and recklessly, whereby it collided with a brougham. Accused denied that he was driving recklessly, or exceeding the normal speed. He applied the electric brake, but it did not take the necessary effect, as the wheels skidded on the rails. Then he applied the hand brake. All this was done before the collision. The coachman had deliberately turned the horse when the car was coming, and if he had been a little smarter he would have got clear. As it was, the brougham was almost clear.

Corroborative evidence was given by the conductor and a passenger.

In summing up, the **Procurator-Fiscal** said the real fault was that the motorman did not apply the brake in time, thinking, probably, that the horse and brougham would get out of the way. If the gong had been sounded previously, there might have been no accident. The drivers of the tramway cars should be exceedingly careful for the sake of passengers and vehicular traffic.

COMPANIES' MEETINGS AND REPORTS.

YORKSHIRE ELECTRIC POWER.

The third ordinary half-yearly meeting was held at the Hotel Metropole, Leeds, on Tuesday. Mr. A. G. Lupton presided over a large attendance of shareholders. Particulars of the report were given in our last issue.

In moving the adoption of the report and balance-sheet, the **Chairman** said that since the last half-yearly meeting the directors had had a busy and somewhat anxious time. The administration expenses during the half-year had been swelled by law charges to the amount of over £900, and he regretted to say there was still a further amount which would appear in the next balance-sheet under the same heading. When the Company's Act was drafted, clauses were included for the protection of local authorities, so that the company could in no case without their consent go into the areas

Digitized by Google

of those authorities who had obtained distributing powers to compete with them. All the rights and privileges which ought to belong to those local authorities were thus amply protected, but in spite of that in several cases during the last session of Parliament local authorities had promoted Bills asking to supply electricity outside their own areas, and to risk the money of their ratepayers by entering into competition with the company. It had been the duty of the directors to oppose those Bills, and so to protect the interests of the shareholders who had invested the large amount of the capital of the Company in laying down plant for that very supply, and he was glad to say that the committees of Parliament before whom the Bills were fought had upheld the action of the directors in the most decisive manner. The directors hoped that now that the Company was at work local authorities would support and make use of the Company rather than waste the money of both sides in payments to the legal profession for profitless fighting. A more satisfactory side of the half-year's work was the progress made with the central supply station at Thornhill, the building being now completed, whilst the plant was being pushed on and erected with all speed. He had every confidence that their promise of being ready to supply current this year would be carried out. He anticipated that when the cheap supply of electric power for small industries was thoroughly understood they would see a very considerable spread of population in all those industries throughout the areas of the local authorities, and one step would be taken to relieve the congestion of population in our big cities. The Company had already arranged the routes for some 12 miles of cables, and further lines were being considered. The Chairman added that payments on account of contracts had not come on quite so rapidly as anticipated, and there was no use in drawing money from the shareholders to lie in the bank. So far as he could foretell, the next call that would be required would fall due for payment early in November.

Mr. Callender seconded the motion, which was carried *nem. con.*

A vote of thanks to the chairman concluded the business.

CHILIAN ELECTRIC TRAMWAY AND LIGHT.

The report for 1903 shows, after payment of interest due on loan account and other charges, a balance to credit of £1,946. From this is deducted the debit balance brought forward from the previous year of £324, leaving a net balance to the credit of profit and loss account of £1,621 to be carried forward. During the 12 months a net profit on the operation of the tramways was made of 512,195dol., from which was written off the sum of 179,469dol., being for amortisation of the horse account, and sundry incidental expenses in connection with construction outlay. The net profit for 1902 was 271,058dol. The above large amortisations, being of exceptional character, will not reappear in future accounts. The number of passengers carried was 52,427,359, an increase of 7,251,442. During 1903 the electric lighting department earned a net profit of 179,723dol., against 113,390dol. in 1902. This result, although showing an advance on the previous year, still falls far short of the expected development of the lighting business, which the directors hope yet to realise, the capacity of the plant being far in excess of the present consumption. As indicated in last year's report, the capital of the Company was increased by the creation of £100,000 additional 6 per cent. cumulative preference shares, ranking *pari passu* with the existing preference shares; £50,000 of the above shares have since been issued.

BURY, ROCHDALE, AND OLDHAM TRAMWAY.

The report of the Bury, Rochdale, and Oldham Tramway Company, Limited, for the half-year ended July 31 last, to be submitted at to-day's meeting at Manchester, shows a gross profit of £2,651. The directors recommend the addition of £1,307 to debenture interest fund, which, with the sum of £15 balance brought forward, enables the payment of £2. 11s. 8d. per cent. per annum, and leaves £13 to be carried forward, and the appropriation of £1,344 as dividend for the shareholders, which, with £35 balance brought forward, enables the payment of 6½ per cent. per annum, and leaves £14 to be carried forward. As regards the sale of the Company's undertaking, since the issue of the last report an arbitration of the whole of the Company's property has taken place, Mr. H. Graham Harris being the referee appointed by the Board of Trade. It will be remembered that he awarded the Company £159,075, exclusive of a sum of £3,600 for street improvements, which was still in dispute, but which the authorities have since agreed to pay. An arrangement was also come to with the Urban Council of Whitefield in regard to the short length of tramway in that district, the Council agreeing to pay the sum of £350, making a total of £163,025. The directors are unable to say whether the sale will be completed within three months from the publishing of the award, but if not, the purchase money will, after the expiration of that period, carry interest at the rate of 5 per cent. per annum, which interest will take the place of the £5,300 now receivable in lieu of profits on working.

PERSONAL.

Mr. R. H. Wilkinson, late general manager of the Oldham Corporation tramways, has been appointed manager of the Huddersfield tramways at a salary of £350 per annum.

The Portsmouth Electric Light Committee have recommended that the salary of Mr. W. S. Foale, the superintendent of the Corporation electric light station, be increased from £300 to £400 per annum.

Mr. F. A. Bond, chief assistant at the Ilford Urban District Council's electricity department, has been appointed by the Heston and Isleworth Council as their resident electrical engineer.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Swansea.—The Corporation invite tenders for two negative tramway boosters. Tenders by noon on Sept. 7. See advertisement.

Lemberg.—The Government Railways require tenders for accumulator battery at the central station at the railway station. Tenders by Sept. 4.

Pretoria.—The Commanding Royal Engineer at Army Head quarters, Pretoria, is calling for tenders for the electric lighting of cantonments.

Mexico.—The Federal District Railway Company of Mexico require tenders for the electrification of six tramway lines in the town. Applications are to be made direct.

Pangbourne.—Tenders are required for lighting the village during the coming winter, for the Pangbourne Parish Council. Particulars may be obtained of Mr. C. West, jun., clerk.

The Hague (Holland).—The Council of the Hague require tenders for the supply of from 8,000 to 9,000 tons of steel rails, including appurtenances, for electric tramways. Tenders by Sept. 22.

Madrid.—Tenders are required by the Post and Telegraph Department for 70 tons of 4mm. galvanised iron wire, about £16 per ton, and 70 tons of 2mm. bronze wire, about £94 per ton, by Sept. 3.

Madrid.—Tenders are required by the Post and Telegraph Department for 9,000m. telegraph cable of 7 rubber-insulated wires, 2,000m. ditto of 28 paper-insulated wires, and 11,000m. cable of 7 steel wires by Sept. 6.

Belmez (Spain).—The Municipality require tenders for electric lighting of Belmez Pueblo Nuevo del Terrible, and Pennarroya for seven years by Sept. 17. Particulars from the Alcadia Constitutional, Belmez, Cordoba, Spain.

Aberdeen.—The Tramways Committee invite tenders for the supply and delivery of 20 top-deck car-covers. Drawings and specifications may be had from Mr. J. Alex. Bell, city electrical engineer, Aberdeen. Tenders by Sept. 27. See advertisement.

Wallasey.—The Urban District Council invite tenders for the supply and erection of high-tension switchgear (which must be of British manufacture) for a sub-station. Tenders to Mr. N. W. Cook, clerk and solicitor, Public Offices, Egremont, Cheshire, by Sept. 14.

London, S.W.—The London County Council invite tenders for the manufacture, delivery, and erection of three electric car traversers at certain of the Council's tramway depôts in the South of London. Specification, etc., may be obtained at the County Hall, Spring-gardens, S.W. Tenders by 10 a.m. on Oct. 4.

Londonderry.—The Corporation invite tenders for the wiring, fittings, lamps, connections, etc., for the electric lighting of the Guildhall. Specifications and further particulars may be had on application to the Electrical Engineer, Strand-road, Londonderry. Tenders to Mr. F. H. Miller, town clerk, before mid-day on Sept. 6.

Edinburgh.—Tenders will be received for the supply of 600 tons (more or less) of cable ropes, for the Edinburgh and District Tramways Company, Limited. Specification may be obtained of Mr. John E. Pitcairn, general manager, 1, South Charlotte-street, Edinburgh, and tenders must be lodged with him in accordance with specification by Sept. 19.

Tschatschak (Servia).—The Electricity Company Owtschar und Kablar in this town require two turbines of 750 h.p. each, two generators for three-phase currents, and other plant for the erection of a hydro-electric central station, and equipment of lines of distribution within 40 miles, by Oct. 2. Specifications, etc., may be obtained from the Manager of the Company.

Swansea.—The Corporation invite tenders for the supply and delivery of two negative tramway boosters. General conditions, specification, and forms of tender can be obtained from the borough electrical engineer, Mr. C. A. L. Prusmann, Strand, Swansea, on payment of £1. 1s. Tenders to Mr. Jno. Thomas, town clerk, Town Hall, Swansea, by noon on Sept. 7.

Leeds.—The Guardians invite tenders for the wiring installation and subway and underground concentric mains for the electric lighting to the several proposed new hospital blocks and other extensive existing buildings at the workhouse, Beckett-street, Leeds. Send names to Messrs. Thomas Winn and Sons on or before Sept. 12 when specifications and full particulars will be forwarded. Each application must be accompanied by a deposit of £3. 3s.

Greenwich.—The London County Council invite tenders for the manufacture, delivery, and erection at the tramways electricity generating station at Greenwich of the following plant: two 24in. centrifugal pumps and motors, one 3in. centrifugal pump and motor, two 8in. by 8in. three-throw air-pumps and motors, one 3in. artesian well pump, fixed and rotary strainers, etc. Specifications, etc., may be obtained at the County Hall, Spring-gardens, S.W. Tenders by 10 a.m. on Oct. 4.

West Ham.—The Town Council invite tenders for the supply, delivery, and erection of all poles, fittings, wires, and pillars required for the electrical equipment of approximately 3 miles 3 furlongs of tramway track in the county borough of West Ham. Specification, etc., may be obtained from the Borough Electrical Engineer, Electrical Works, Canning Town, E., on deposit of a £5 Bank of England note. Tenders to Mr. Fred. E. Hilleary, town clerk, Town Hall, Stratford, E., by 4 p.m. on Sept. 13.

London, N.—The Edmonton Urban District Council desire to enter into an arrangement with a company for the exercise of their powers under their provisional order. They are prepared to consider offers based upon certain alternative arrangements, particulars of which are set out in the form of tender. Particulars and form of tender may be obtained at the office of Mr. William Francis Payne, clerk, Town

Digitized by Google

Hall, Edmonton. Tenders must be addressed to the Clerk, and delivered by 12 noon on Sept. 27.

La Rochelle (France).—The Chamber of Commerce will shortly issue tenders for a crane with a lifting power for 30 tons. The beam, or the part which projects over the water or vessel alongside, should be long enough to unload from a point about 26ft. 6in. from the edge of the quay. The height of the distal end above the quay should be 15m. (49·21ft.); the vertical distance between the edge of the quay and that part of the crane directly over it, 8m. (26·4ft.). A locomobile is preferred, but should the conditions be unfavourable for installing such a machine, then a fixed crane would be adopted.

Barking (Essex).—The Urban District Council invite tenders for the construction of light railways as follows: (Contract No. 1 and 1A) rails, fishplates, and bolts; (2 and 2A) permanent way construction); (3 and 3A) overhead line equipment; (4 and 4A) underground feeder cables, etc. Specification may be obtained of Mr. H. Hargreaves, clerk, Public Offices, Barking, Essex, on depositing a cheque for £5. 5s. Applicants to state the contract for which they propose tendering. Tenders to Chairman of the Electricity and Tramways Committee, Council Offices, Barking Town, by 12 noon on Sept. 20.

Australian Commonwealth.—Tenders will be received at the office of the Deputy Postmaster-General, Hobart (Tasmania), until noon on Sept. 30, 1904, for the supply and delivery at the General Post Office, Hobart, of one multiple metallic branching switchboard. Specifications may be seen at, and tender forms and conditions obtained from, the General Post Offices at Hobart, Melbourne, Sydney, Adelaide, Brisbane, and Perth. Tenders should be endorsed "Tender for Switchboard," and addressed to the Deputy Postmaster-General, Hobart. Tenders may be deposited in the tender-box at the General Post Office, Hobart, or, if sent by post, must be prepaid and registered. Tenderers must state the name of the country in which the switchboard will be manufactured.

Madrid.—The call for tenders for the service of the electric lighting of Pueblo Nueva del Terrible and Penarroya was without result. The conditions of tender have therefore been modified in certain respects, and a new adjudication is announced to take place on Sept. 18. Tenders are also required for the supply of 25,000 porcelain telegraph insulators, No. 1 of the Spanish type. Tenders, which must be accompanied by a proof that 5 per cent. of the amount has been deposited, will be received at the office of the Direction General of Posts and Telegraphs, No. 10. Carretas, 2° Madrid, up to Sept. 16. The *Gacetas* containing the above notices may be seen by persons interested on application at the Commercial Intelligence Branch of the Board of Trade, 73, Basinghall-street, E.C., any day between 10 a.m. and 5 p.m. (Saturdays, 10 a.m. to 1 p.m.).

RESULTS OF TENDERS.

Pontypool.—The tender of the Pontypool Electric Light Company has been accepted for one year's labour connected with the maintenance of the electric installation in the market, the amount being £5. 5s.

Stoke-upon-Trent.—The Guardians have accepted the tenders of Morley Electrical Engineering Company, Leeds, for motors at £147, cable at £98. 7s., tubes at £32. 17s.; and Dean and Lowe, Stoke, for junction boxes, etc., at £15. 16s.

Dartford.—The Urban District Council have accepted the tender of the Western Electric Company, North Woolwich, at £850. 6s. 10d., for carrying out an extension of underground and pilot cables drawn into existing spareways, and for the laying of private and public lighting cables, together with all necessary roadwork, junction boxes, etc.

Wimbledon.—The Urban District Council have received the following tenders for boiler-house extensions, with Bennis stokers:

	A.			
Richardsons, Westgarth, and Co., Limited	3,615	£4,890	0	0
Musgrave and Son	3,615	5,023	10	0
R. Hornsby and Son	3,615	5,023	10	0
E. Le Bas and Co.	3,615	4,885	0	0
Babcock and Wilcox	3,654	4,870	0	0
Stirling Company (U.S.A.)	3,678	4,975	0	0
Richardsons, Westgarth, and Co., Limited	4,000	5,083	0	0
Babcock and Wilcox (accepted)	4,020	5,069	0	0
Stirling Company (U.S.A.)	4,095	5,100	0	0
Stirling Boiler Company (Meldrum stokers).....	4,100	5,365	0	0

A. Heating surface in square feet of each boiler. The specification called for not less than 4,000 square feet of heating surface.

BUSINESS NOTES.

TRACTION.

Durham.—The Durham Miners' Association favour an electric service by the County Council.

Tyneside Tramways Co.—A further issue of £40,000 5 per cent. mortgage debentures is announced. The subscription list closes on the 10th inst.

Newport (Mon.).—The number of passengers carried on the tramways last week was 126,444, the receipts amounting to £533. 10s. 8d., against £473. 5s. 4d. last year.

Yarmouth.—The extension from St. Peter's-road to Queen's-road was commenced by the Corporation on Monday, and already considerable progress has been made with the work.

Cardiff.—The number of passengers carried on the tramways last week was 503,099, the receipts being £2,194. 6s. 1d. The receipts for the corresponding period last year amounted to £2,035. 5s. 10d.

Newcastle.—The cars of the Tyneside Company made their appearance on the Corporation lines last Monday. The municipal trams commenced running on the company's rails some days previously.

New York Underground.—The cost of constructing and equipping the Manhattan section, which has been completed, and is expected to be opened in two or three weeks, amounts to something over £11,000,000.

Manchester.—The Corporation have inaugurated a system of payment of fares by "tokens" in the form of celluloid discs, which can be purchased at the rate of 5s. and 2s. 6d. for packets of 60 1d. and ½d. "tokens" respectively.

Pudsey.—There is stated to be a considerable amount of antagonism to the proposed municipal electric tramway on the part of tradesmen, who contend that it will take their customers to the large adjoining towns of Leeds and Bradford.

King's Norton.—At a public meeting a resolution calling upon the District Council to negotiate with the Birmingham Corporation instead of the company for the working of the lines in King's Norton and Northfield was unanimously carried.

London County Council.—The work of widening the roads from New Cross by way of Brockley to Forest Hill for the new tramlines was begun on Monday, and a commencement is to be made shortly on the line from Camberwell-green to Denmark-hill and Lordship-lane.

Llanelly.—A special meeting of the Council will be held to-day in reference to the electric traction and lighting scheme, when the agreement with the British Insulated and Helsby Cables, Limited, will be discussed, and, it is hoped, an end put to the long-standing deadlock.

Devonshire Light Railways.—The Light Railways Commissioners have submitted to the Board of Trade for confirmation an order made by them authorising the construction of light railways in the county of Devon from Newton Ferrers to Yealmpton, and from Kingsbridge to Slapton, and to Salcombe.

Wirral Railway and Electrification.—At the half-yearly meeting of the Wirral Railway Company held at New Brighton on Monday, Mr. T. H. Jackson (the chairman) said the directors had not lost sight of the possibility of electrical development, but they were waiting for further evidence of its efficiency.

Alsace-Lorraine Electric Railway.—It is reported that a Belgian company has obtained a concession, in accordance with an understanding between the French and German Governments, to construct an electric railway from Moyeuvre la Grande to Joeuf and Homecourt. This will be the first railway connecting Alsace-Lorraine with an exclusively French district.

Dover.—The annual report of Mr. E. Carden, the Corporation electric tramways manager, records gross receipts of £11,840, against working expenses of £6,442. After allowing for interest, sinking fund charges, and general expenses, a net profit of £920 remains. The mileage totalled 280,901, the service being considerably interfered with through alterations to the lines. The energy consumed totalled 319,413 units.

Perth.—Trials were made with the petrol cars on Tuesday, the first one, it is reported, running smoothly and easily. A second car was less successful in dealing with the inclines, though stated to have given every satisfaction on the level sections. The promoters of the system are confident that they can provide an efficient service for £10,000, including new rolling stock. The lowest offer for the trolley electric system is stated to have been £43,000.

Brighton.—A report of the general manager, Mr. T. B. Holliday, deprecating the suggestion of a councillor that a portion of the trams on all routes should run to the railway, has been approved by the Tramways Committee. The manager considers that such an arrangement would disorganise the traffic, but adds that when there is an extension to the eastern part of the borough cars could be run through from the eastern terminus to the railway station.

Falkirk.—It was recently reported that the company which in 1901 obtained parliamentary powers to make and work electric tramways in this district, had made arrangements for selling its rights to a member of an Edinburgh firm of electrical engineers, who intended promoting a limited company to undertake the business. It is now stated that this transaction has been challenged by a member of the original company as being *ultra vires*, and that, if an attempt is made to carry it out, it will be opposed.

Burnley.—The tradesmen of Nelson are complaining at the charges which the Corporation make for carrying parcels on the tramways. To send a parcel to Brierfield, a Nelson tradesman has to pay 3d., whilst the same parcel can be sent to Burnley for 2d. No extra labour is involved, as the receiving office at Brierfield is in line with the regular stopping place at the centre. Rather than submit to the anomaly, the tradesmen are sending the parcels on the car by their assistants, who can travel the return journey for 2d.

Sheffield.—It is expected that at the next meeting of the Corporation there will be a discussion in reference to the powers for tramway construction conferred by the Corporation's Acts of 1897 and 1900. Nearly all the routes comprised in the former measure are in use, but several included in the latter have not been undertaken. The *Sheffield Daily Telegraph* has "reason to believe that the Tramways Committee will recommend the Council to allow the unused powers under the 1897 Act to lapse, and to defer the whole question of extensions for three years, when the term of the second Act expires."

Derby.—A trial trip was made on Tuesday on the Burton-road route. The Board of Trade inspection of the routes comprised in the first contract which have not yet been opened will take place on Tuesday next, after which they will be opened for the use of the public. The opening of the new tramway offices and waiting-rooms in Victoria-street is expected to be almost simultaneous with the opening of the remaining routes. The Tramways Committee received on Tuesday a

Digitized by Google

deputation of inhabitants who requested that the Market-place should be adhered to as the terminus for the cars on the Midland Railway Station route instead of selecting Victoria-street for the purpose. The committee promised that their representations should have careful consideration, and an early answer will be given.

Maidstone.—The following particulars were given at last week's meeting of the Council in reference to the progress of the new tramways. The number of units used between July 14 and Aug. 21 (inclusive) was 9,862, and the numbers carried were 57,640 ½d. passengers, 144 100 1d. passengers, 14,400 2d., and 19,250 3d. passengers. The total, exclusive of season-ticket holders, was 235,390. This worked out at an average of 6,726 a day, or 47,082 passengers a week. The fares amounted to £1,130, and the season tickets to £45. 1s. 6d., while there was £25 for advertisements on the tickets. In the first week £194. 16s. 3d. was taken, in the second £174. 6s., in the third £242. 3s. 7d. (bank holiday week), in the fourth £183. 17s. 1d., and in the fifth £177. 0s. 3d. Some of the speakers advocated a line in the St. Paul's district.

Hull.—The American Consul having reported to the United States Department of Commerce and Labour on the excellent results achieved by the municipal trams, the subject has been commented upon by several American journals, including the *Scranton Tribune*, which states: "The results in Hull are due to limiting capitalisation to actual cost of track and equipment, without any inflation for franchise values or the enrichment of promoters and speculators working through venal councilmen. They are enhanced by a public sentiment for honesty and economy in city administration. None of these things is yet dominantly present in American cities. They may come in time; if they don't, we shall have to shut up shop. But they are not in sight. Our over-capitalisations are the direct result of our civic carelessness and lack of assertive honesty, and from it come the high fares and relatively inferior service which our public has to put up with in order to pay for bribery, stock-watering, and skin-game financiering. We can undoubtedly do as well as Hull when we have the general determination, and when we can extricate ourselves from our entanglements through past mistakes; but this is some distance off."

Belfast.—In reference to the proposed appointment of Mr. Andrew Nance as manager of the Corporation tramways, the Belfast Trades and Labour Council passed the following resolution last Saturday by 26 votes to 11 after a somewhat heated discussion: "That this meeting hereby calls upon the Corporation to make their appointment of tramway manager after advertisement, selecting the best applicant, the appointment to be made on merit, and we strongly protest against the attempt now being made to foist Mr. Nance into the position of manager, a position which all his previous attitude towards municipalisation of the tramways absolutely unfits him for." A deputation subsequently attended before the Tramways Committee requesting that no appointment to the managership should be made without advertising. The town clerk having submitted replies he had received from Birmingham, Leicester, Leeds, Bradford, Manchester, Liverpool, and other cities relative to the salaries of their tramways managers and the conditions attached to the appointment in the different cases, the committee discussed the following resolution, which was several times amended, and finally carried by 10 votes to 2: "That it be a recommendation to the Corporation to appoint Mr. Andrew Nance as manager of the tramways undertaking on the terms contained in his proposal, but modified as follows—viz., that all actions as manager be subject to and under the control of the committee, and that the appointment be terminated at six months' notice on either side, and without any right to pension, and that an agreement be prepared accordingly by the town clerk."

Heywood.—A meeting of the Tramways Committee was held on Thursday of last week to consider the terms submitted by the Corporations of Rochdale and Bury for the construction and working of the lines in the borough. The terms now proposed include the payment by Rochdale and Bury of Heywood's share of the purchase price of the old undertaking, the leasing of the new lines to the two Corporations for a period of 30 years, the Heywood Corporation to construct their own section and maintain it, and the Rochdale and Bury Corporations to pay 10 per cent. per annum on the total cost of construction to cover maintenance and interest. The difference between these terms and those which according to Heywood were originally offered, is that the lease is extended from 21 to 30 years, and it is also contended by Heywood that in the first proposals the pavement of the track was to be granite throughout. The present terms provide for a granite track from Heywood Market-place to Crimble-lane on the Rochdale side, and from the Market-place to the summit on the Bury side, the remainder to be laid with ordinary setts unless Heywood chooses to pay the difference in the cost of substituting granite. After discussing these terms the Tramway Committee decided to approach the Bury and Rochdale Tramways Committees with a view to a joint conference. Just as we go to press we learn that a conference has been held in the Council chamber, Heywood, between representatives of the Tramways Committees of Heywood, Bury, and Rochdale in reference to the further proposals made by Bury and Rochdale. The questions of the term of lease and which authority should supply the electric power were discussed. The points in dispute were not settled, and a further conference will be held.

Salford.—The annual report of the general manager of the Corporation tramways for the year ended March 31 has just been issued. The total length of tramways now worked by the Corporation is 59½ miles (single track). The stock of cars on March 31 was 150, of which 100 are of the double-decked single-truck type, and 50 double-decked bogie cars, all the cars having staircases of the reversed type. Several experiments having been successfully tried during the year with outer deck coverings fitted to the cars, it was decided to equip 20 of the single-truck cars with covers of an approved type. These cars were much appreciated, and an early addition to them is contemplated. Considerable maintenance works have been carried out during the year. The traffic returns show largely increased gross receipts, although a decrease in the earnings per car mile has resulted, due to the unfavourable weather. The number of passengers for the year was 36,956,405, an increase of 8,805,730 as compared with the preceding year. The receipts were £53,936. 5s. more last year than in the previous year—£198,422. 7s. 6d., against £144,486. 2s. 6d. The year's working resulted in a gross profit of £60,106. 14s. 11d., to which must be added the sum of £242. 2s. 9d. for interest on investments, making a total available balance of £60,348. 17s. 8d., and this has been dealt with as follows: payment to local authorities for running powers, etc., £10,903. 4s. 5d.; interest and sinking fund charges, £34,005. 14s. 2d.; contribution in relief of rates, £12,000; reserve and renewals fund, £3,439. 19s. 1d. The amount now standing to the credit of the reserve and renewals fund is £12,202. 10s. 4d. Some fatal accidents occurred during the year, besides which there was a large number of minor injuries through passengers attempting to board or leave the cars whilst in motion. All the cars are provided with lifeguards of the gate and cradle type, and on many occasions these have been the means of saving lives.

Live-Rail Dangers.—The following views have been expressed in reference to the recent Board of Trade reports. Mr. R. Bell, M.P., secretary of the Amalgamated Society of Railway Servants, in the course of an interview, agreed that it might be unnecessary to provide boarding for the "live" rails in certain sections of the line where there was little traffic. The platelayers would certainly need less protection in that way than any other of the employés on the line. They would naturally be best acquainted with the "live rail," and would be most able to avoid all danger from it. The classes which needed most protection are those who were employed in other branches of work, such as porters, guards, drivers, and firemen, who only went occasionally on the line. If they were in danger they ought to be protected. However difficult it might be to protect the line, it must be done where there is danger to the men employed at work other than dealing with the repairs of the line itself. A prominent official of the Board of Trade remarked to a *Daily Chronicle* representative: "You must understand that the Board of Trade has no control over the method of laying the lines. It is only when an accident occurs that our inspectors can hold an enquiry and make recommendations. I must say that, as a rule, the Board finds the railway companies very ready to fall in with suggestions, and to do all that is possible to ensure the safety of the public. Electricity is still a very new method of traction, but it has evidently come to stay, and probably in a comparatively short time it will be in general use on all suburban railways, if not for long-distance traffic. Consequently the best methods of guarding 'live' rails will be carefully considered both by the Board and the companies. It is important to notice that of these accidents only one occurred to a railway employé, the other two happened to trespassers on the line. People are constantly killed or injured on ordinary railways through walking on the line, crossing where they ought not, and so on." Mr. H. A. Watson, general superintendent of the Tyneside line, stated to a representative of the *Yorkshire Post* that the North-Eastern Company were earnestly considering various methods for adequately safeguarding the public against the dangers of the "live" rail. Mr. Cunningham, manager of the Central London Railway, remarked that there was but little danger on that line, but he welcomed investigation into such dangers, as he was convinced that protection against them would be greatly facilitated hereby.

LIGHTING AND GENERAL.

Pittenweem.—The telephone system is being extended by the Post Office from Leven to Anstruther.

Ashford.—The Ashford electric lighting order received the Royal assent just before the prorogation.

Buncrana (Ireland).—At a public meeting resolutions were passed in favour of an electric lighting scheme.

Sales.—Particulars will be found in another column of a sale of private electric light plant by Messrs. Brackett and Sons at Finchley; also of an electrical contractor's business for sale.

Ravensthorpe.—Terms have been discussed between the Urban District Council and the Yorkshire Electric Power Company in regard to the supply of energy by the latter in the event of the Council obtaining a lighting order.

Stockton-on-Tees.—The income for the year ending March 31 amounted to £5,432, against which have to be placed £3,123 for working expenditure and £3,278 absorbed by interest and sinking fund charges, leaving a deficit of £969.

Northampton Institute.—Full day courses in the theory and practice of the engineering, electrical, and horological engineering subjects will commence on Monday Oct. 3, 1904. The examination will take place on Wednesday and Thursday, Sept. 28 and 29. The evening technical courses in all branches of electrical and mechanical engineering will commence on Monday, Sept. 29, 1904. Particulars appear in another column.

Hampstead.—The annual report of Mr. G. H. Cottam, the borough electrical engineer, chronicles further records. 575 customers being connected during the year, and number of lamps totalling 32,489. The income aggregated £58,051, and after payment of all charges a surplus of £5,796 remains, out of which £3,212 are to be contributed to the local rates. The energy sold consisted of 678,585 units, which is an advance upon any previous year. The charges for power have been revised with a view to encouraging a day load. Considerable additions to the mains were made during the year, and three new sub-stations have been erected. The new customers for power include the contractors for the Charing Cross and Hampstead Railway.

Digitized by Google

Barnstaple.—The engineer is preparing a report as to the cost of lighting High-street with arc lamps.

Todmorden.—The laying of the electric cable for the Corporation electric lighting works in course of construction at Millwood has been begun.

Mile End.—The Guardians will shortly require a dynamo in connection with the electric lighting of the old school buildings. The estimate is £500.

Chester.—At the expiration of the vacation the question of a refuse destructor is to again come before the Town Council in the shape of a report by the city surveyor and the electrical engineer.

Leeds.—The Corporation Lighting Committee on Tuesday resolved that all the tramway routes in the city should be lighted by electric arc lamps for a mile from the junction of Briggate and Boar-lane.

Yorkshire Electric Power Co.—With regard to a note that appeared in a former issue, we are informed by this company that electric power will be available from the Thornhill station in December next.

Fire.—With regard to a fire which occurred at the works of Messrs. J. G. Statter and Co., Newhall-street, Birmingham, we are informed that it was only a small affair, and that the damage was slight and entirely covered by insurance.

Stourbridge.—The District Council on Monday dismissed the Electric Power Committee's recommendation that steps be taken to procure a provisional order under the Electric Lighting Acts in regard to the parishes of Pedmore, Hagley, Clent, and Belbroughton.

W. T. Henley's Telegraph Works Co.—The directors of W. T. Henley's Telegraph Works Company, Limited, have declared an interim dividend on the ordinary shares at the rate of 10 per cent. per annum, less income tax, for the half-year ending June 30 last.

St. Pancras.—The Guardians have decided that the workhouse shall be lighted throughout with electric light, and that a sum of £550, being a moiety of the estimated cost of wiring, etc., be included for this purpose in the next precept for rates made on the Borough Council.

Tiverton.—From the account of the Local Government Board enquiry in our issue of the 26th ult. it appeared as if Mr. J. S. Enright had attended as representative of Messrs. Frank Suter and Co., Limited, while as a matter of fact Mr. Enright is the consulting engineer to the Town Council, and gave technical evidence on their behalf.

Stock Exchange.—The Stock Exchange Committee have appointed Sept. 7 special settling day for the North Wales Power and Traction Company's 34,100 shares of £5 each, £4 paid, Nos. 1 to 34,000 and 37,401 to 37,500, and have ordered the Metropolitan District Railway Company's £500,000 4 per cent. perpetual debenture stock to be quoted in the official list in lieu of the scrip now quoted.

Keighley Association of Engineers.—About 20 members of the Keighley Association of Engineers last week visited the works of Sir William Gray and Co., Limited, shipbuilders and engineers, West Hartlepool, where a great expenditure is now being made in installing electric driving to replace the original steam power plant. These works employ about 1,200 men, and 2,000 are engaged in the shipyards.

Stockport.—The Guardians have decided with regard to installing the electric light in the infirmary buildings to advertise for competitive schemes, with reports and estimates of cost, of an electric lighting installation both with Guardians' own plant and with Corporation supply. The schemes sent in are to be submitted to an assessor. A premium will be awarded to the one highest in order of merit.

Llanwrtyd Wells.—It is proposed to form a company to generate electricity for the purpose of lighting the village, and also for traction purposes to convey visitors to and from the village to the Wells, a distance of about half-a-mile. It is thought that there is sufficient water to drive a dynamo to generate the necessary power. The capital of the company will be about £2,000, divided into £10 shares.

Hammersmith.—The Guardians have received from Messrs. R. Waygood and Co. an estimate for supplying two electric lifts to the new infirmary at Wormwood Scrubbs—viz., two lifts at £380 each, £760; two enclosures at £55 each, £110—total, £870; £11 extra per lift to be charged if wiring below the balusters is required. The acceptance has been left with the Building Committee and the architect.

Southwark.—At the last meeting of the Guardians a specification for installing incandescent governed lights to the wards and corridors and other suitable places in the infirmary was considered. The cost of installing incandescent light is £400, and it was suggested that the Board might consider the advisability of having electric light in the infirmary. After the initial cost of the installation a saving would be effected of £250 or £300 a year. The matter was referred to committee.

Wellingborough.—In consequence of a report on the proposed agreements with the Electric Power Distribution Company, Limited, and the County of Northampton Electric Power and Traction Company, Limited, respectively, the surveyor has been instructed to prepare plans and estimates at once with a view to applying to the Local Government Board for a loan for the purpose of providing the machinery necessary for enabling the Council to generate its own electrical energy.

Angus Electric Light and Power Co.—The shareholders, in special meeting, have decided to alter the name of the company to the North of Scotland Electric Light and Power Company, Limited, to increase the ordinary share capital to £100,000, and to issue £25,000 of debenture stock. This step has been taken in view of arrangements being made for taking over the provisional order for supplying electricity in Inverness, and for extensions to the supply of Montrose and Brechin.

Radcliffe.—The ceremony of switching on the electric light in the market hall, which is the first public building to be lighted by current from the electricity station, was performed on the 19th ult. by Mr. J. H. Lund, chairman of the Electricity Committee. The market has been fitted up with 20 clusters of lamps, five lamps each, of 25 c.p., in each cluster, a wonderful improvement in the lighting. The installation has been put in by Mr. Wm. Brierley, of Church-street.

Hackney.—The Guardians have decided that the Electrical Standardising Institute, of Charing Cross-road, be engaged as clerk of the works to supervise the work to be executed by Messrs. Wm. Wallace and Co., Limited, in connection with a system of electric fire-alarm bells at the workhouse, infirmary, and children's homes, at an inclusive fee of 5 per cent. on the value of the work executed. The institute will test all fittings and wire, and supervise and pass all work, visiting the site daily for the purpose.

Colliery Contracts.—Messrs. Graham, Morton, and Co., Limited, Leeds, report the following contracts: (1) Doncaster Corporation gas-works, for the supply of a coal elevating and conveying plant for unloading the barges and distributing the load to the stores; (2) a large plant on this system for H.M. Government at the Royal Gunpowder Factory, Waltham Abbey; and (3) a contract for the supply and erection of a large complete coal-screening plant for the Wheldale Colliery Company, Limited, Castleford.

An American Earl's Court.—We have received from the Edison Electric Illuminating Company, of Brooklyn, N.Y., a copy of the August number of their monthly publication, "The Brooklyn Edison," which is interesting in view of the exceptional illumination features described therein, relating to Coney Island. Enormous sums have recently been spent on this pleasure resort, and the lavish yet most artistically arranged use of the incandescent electric lamp is one of the foremost factors of its success. The illustrations in the booklet giving details of the electric lighting of Dreamland and Luna Park fully bear out the enthusiastic reports we have seen anent this place lately.

Whitehaven.—The Harbour Commissioners have agreed to the last proposal of the Town Council in regard to the harbour lighting contract—viz, that the price for electric energy be 3½d. for lighting and 4d. for motor power; that the Town Council provide and maintain all the means of lighting of an agreed scheme; that the Town Council pay £12. 10s. a year, half the premium on a policy insuring the harbour against possible accident owing to failure of light from any cause, and that the Harbour Commissioners agree to pay a minimum of £350 a year for their energy, whether they consume to that value or not, the £350 to merge in the charge per unit if a greater value be consumed.

Barking.—The accounts of the District Council's electricity department, of which Mr. A. Hugh Seabrook, A.M.I.E.E., A.M.I.Mech.E., is the engineer and manager, again show a surplus. The cost of generating was £2,493, while £4,103 was received for current at rates from 1½d. to 4½d. per unit, £2,443 for public lighting. The gross receipts were £6,619, and the gross expenditure £4,019, leaving £2,900 to be carried to net revenue account. The interest on mortgage debt amounted to £1,371, and the instalments of money borrowed to £1,487. About 10 per cent. of the amount borrowed has been repaid. The following statement is appended: quantity generated in Board of Trade units, 664,246; quantity sold—public lighting (estimated), 214,268; private lighting and power, 231,810; traction, 41,656—total sold, 487,734; quantity used on works, 125,087; quantity used in distribution, 51,425; maximum demand on feeders, 375 kw.

Barnsley.—An enquiry will be held to-day into the Council's application for sanction to borrow £6,868 for electric lighting. At the last meeting of the Council the Electricity and Lighting Committee recommended that incandescent electric lamps be supplied at the works for cash, at cost price, to anyone desiring them. A view being expressed that the proposal savoured somewhat of municipal trading, and that it was not desirable that the Corporation should enter into competition with local tradesmen, the Mayor said the reason they had decided to adopt that course was that there were a large number of inferior lamps being sold in the borough, and justice was not done to the Corporation's works, which were blamed for the inequality of the energy they were sending out. They had been blamed for the electricity being more expensive when they knew they were not to blame, but an inferior type of lamp was. They had adopted the step in justice to themselves and for the credit of the light. The minute was agreed to.

Maidstone.—The Electricity Committee reported at the last meeting of the Urban District Council that they had prosecuted a person for stealing electricity, with the result that the defendant was fined 40s. or a month's imprisonment. They recommended that the salary of Mr. Saunders be increased from £2 to £2. 5s. per week, and that the Finance Committee be requested to take the necessary steps to raise another £6,000 for extension of plant, mains, etc. The recommendations were adopted. The profits for the year ending March 31 last (the second year of working) have been enough to clear off the charges for the year for interest and repayment of principal, but there is a deficiency of £1,275, owing to the way in which repayment of principal has to be made. If three years' grace had been allowed the town would only actually have lost £716 on the first year's working, and on the second year would have made, after the payment of interest, a clear profit of £899, in all equal to a dividend of 5 per cent. They have made a gross profit on the year of £2,508, and there has been a considerable increase all round, the revenue for the past year showing an increase of £1,257 on that of the previous year, while the extra total works costs has only been £220. In the year 1902 the cost averaged nearly 2½d. per unit, but in 1903 it averaged less than 1¾d. Over 20 per cent. of the output was now supplied for power, and the increase in the number of units generated amounted to over 50 per cent.

Aberdeen.—The electric light accounts for the year from July 31, 1903, to July 31, 1904, have just been issued in proof, as prepared for submission to the Town Council by Mr. P. M. Cran, C.A., the gas treasurer, and certified by Mr. James Milne, C.A., the auditor. The *Aberdeen Daily Journal* says: "We find that with regard to loan capital, the total amount authorised by the Secretary of State to be borrowed is £250,000, but the Corporation is still within that amount, as there remains a balance of £12,964. Under the heading of capital account, we find that the amount of expenditure on buildings, machinery, mains and services, less depreciation, and adding expenditure for the year to July 31, 1904, is £220,742. The revenue account shows the total revenue to be £38,209, as compared with £30,336 for the previous year, while the expenditure amounts to £17,135, leaving a balance of £21,073 to be carried to net revenue account. The principal item of revenue is £24,394 derived from the sale of electric current, the sum of £2,782 being got for public lighting. The cost to the Corporation for taxation is £9,517. On the expenditure side the largest item is that of fuel, which cost £6,251; taxes swallow up £2,370; main and service repairs absorb £1,824; wages at generating station, £1,821; and repairs on plant, £1,204; repairs on meters, and depreciation, £672. For oil, waste, water, and engine-room stores the figure paid is £465; repairs on buildings, £332; management, £289; proportion of engineers' salary, £458; general establishment charges, £251; special services, £362; and abatements, £227. The amount of reserve fund at July 31, 1904, was £13,196. From a statement of the amount of electricity generated, etc., it appears that the demand for the current continues largely to increase. For 1904 the quantity generated in Board of Trade units was 4,158,141, as compared with 2,987,487 in 1903. In the latter year the quantity used in the public lamps was 1,085,306, and for 1904 it is 1,698,314. For electric traction the quantity used was 1,698,314, as compared with 1,085,906 last year. The quantity of electricity served out to private customers as gauged by meter was 1,581,909, as compared with 1,274,790 for 1903. In the works the total quantity of electricity used was 324,164, as compared with 160,004 in the previous year. The total quantity accounted for is 3,863,190, and not accounted for, 294,951, the loss being 7·09 per cent., the lowest percentage since the inauguration of the works in 1894. The number of public lamps in the city is 187 arc lamps, the same as last year. The price of electricity per Board of Trade unit is 6d. and 2½d., 6d. and 2d., 3d. and 1d., 2½d. and 1·64d. Deducting depreciation, the total expenditure on land and buildings, machinery, accumulators, mains and services, electrical instruments, etc., amounts to £220,742."

COLONIAL NOTES.

India.—With regard to the electric installation at the general offices, E.I.R., *Indian Engineering* says that the sanction of the Government of India has been granted to putting the work in hand without delay. Some 100 additional fans and 200 additional lights will be provided. The installation will cost about Rs.60,000. In their new contract with the Bombay Telephone Company, the Bombay Municipality have, in view of the introduction of electric traction on the Bombay tramways, stipulated that whenever necessary the company shall lay their wires underground. The company has very readily assented to this reasonable proviso, intended as much for their own convenience as for the protection of the public, and have already pulled down the overhead wires in the crowded streets opposite the Crawford Market and substituted underground wires.

Auckland (N.Z.).—Mr. Goodman has reported on a scheme for installing an electric lighting and power service for the city. He estimates the expenditure at £74,000, and the yearly profits obtainable at £6,000. He says the only possible motive power was steam, the water power from the Waitakerei being insufficient and the Waikato too far away. The question will be fully discussed at an early special meeting of the City Council.

PROVISIONAL PATENTS, 1904.

AUGUST 22.

18141. Improvements in electric block systems for railways. Frederick Chadwick Robinson, Fife House, Kingston-on-Thames. (Date applied for under Patents Act, 1901, Aug. 22, 1903, being date of application in United States.) (Complete specification.)

18162. Improvements in arc lamps. Joseph Devonport Finney Andrews, 2, Park-avenue, East Sheen, London.

18163. Improvements in arc lamps. Joseph Devonport Finney Andrews, 2, Park-avenue, East Sheen, London.

18173. Improvements in vapour electric apparatus. Edgar Alfred Carolan, 83, Cannon-street, London. (The General Electric Company, United States.)

18174. Improvements in speed-changing mechanism. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

18181. Improvements in telegraph transmitters. Willis Joseph Roussel and Alphonse King, 18, Southampton-buildings, Chancery-lane, London. (Complete specification.)

18185. Improvements in means for controlling electric power distributing systems. Joseph Louis Routin, 18, Buckingham-street, Strand, London. (Complete specification.)

18199. Improvements in and relating to controllers for electric circuits. Charles Cornfield Garrard, 18, Southampton-buildings, Chancery-lane, London.

18201. Improvements in electric motor control systems. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

18202. Improvements in electric motor control. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

18203. Improvements in electric motor control systems. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

18204. Improvements in transformers, especially adapted for use on electric vehicles. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

AUGUST 23.

18208. Improvements for effecting telephonic intercommunication. John Young, 21, Gloucester-walk, Campden-hill, Kensington, London.

18225. Improvements in electrical switches. Julius Peschek, 5, Budge-row, London.

18252. Improvements in automatic electric telegraphic transmitters. Oster Henn, 21, Glockengiesserwall, Hamburg, Germany. (Complete specification.)

18255. Improvements relating to the parallel running of dynamo machines. The Honourable Charles Algernon Parsons and George Gerald Stoney, 18, Southampton-buildings, Chancery-lane, London.

18280. Improvements in magneto-electric machines. Frederick Richard Simms, 4, South-street, Finsbury, London.

18293. Improvements in controllers for electrically-operated capstans and the like. William Harding Scott, 47, Lincoln's-inn-fields, London.

AUGUST 24.

18306. Improvements in apparatus for electric advertising. Joseph Culshaw, 64, Barton-arcade, Manchester.

18316. Improvements in electrical measuring instruments. Kenelm Edgcumbe and Edgar Isaac Everett, 151, Great Saffron-hill, London.

18317. Improvements in electrical switches. John Alexander Kennedy McGregor and Harry Wren, 5, Corporation-street, Birmingham.

18322. A system of electric lighting for railway trains. Henri Pieper and Gustave L'Hoest, 24, Temple-row, Birmingham. (Complete specification.)

18342. Improvements in electric incandescent lamps. James Wiley Phelps, 46, Lincoln's-inn-fields, London. (Complete specification.)

18343. Improvements in electric incandescent lamps, connections and switch mechanism therefor. William Joshua Phelps, 46, Lincoln's-inn-fields, London. (Complete specification.)

18356. Improvements in electrolysers. Friedrich Ludwig Bartelt, 6, Bream's-buildings, Chancery-lane, London.

18358. Improvements in electric measuring instruments. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

18359. Improvements in incandescent electric lamp sockets. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

18361. Improvements in resistances for electrical apparatus. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

18369. Improvements in trolleys for electric cars. George Raeburn Robson, 37, Chancery-lane, London.

18378. Improvements in and relating to combined electric switches and fuses. Benjamin Shuttleworth Hornby, 322, High Holborn, London.

18383. An improved indicating device for electrical fire-alarms. Reinhold Hoenicke, 18, Buckingham-street, Strand, London. (Complete specification).

AUGUST 25.

18403. An improved electrolytic process and apparatus therefor. Clinton Paul Townsend, Olun House, Surrey-street, Strand, London. (Complete specification.)

18429. Improvements in selective telephone call mechanism. Henry Ivins Hawxhurst, 18, Buckingham-street, Strand, London. (Complete specification.)

18439. Improvements relating to the charging of accumulators or secondary batteries. Robert Shaw McLaren, 7, Southampton-buildings, Chancery-lane, London.

18446. Improvements in vapour electric apparatus. Edgar Alfred Carolan, 83, Cannon-street, London. (The General Electric Company, United States.)

18447. Improvements in or relating to vapour electric lamps. Edgar Alfred Carolan, 83, Cannon-street, London. (The General Electric Company, United States.)

18448. Improvements in vapour electric apparatus. Edgar Alfred Carolan, 83, Cannon-street, London. (The General Electric Company, United States.)

AUGUST 26.

18464. An improvement in electric trolley heads, with wire-finding apparatus attached. John Thomas Cherry and Edward Henry Clive, 2, Bedford-park, Plymouth.

18469. Improvements in trolleys for electric tramways and railways. John Ernest Bentley, 51, Deansgate-arcade, Manchester.

18496. An improved switch for electric circuits. James George Farquhar, 55, Chancery-lane, London.

18499. Improved system of cable connections with electrified railways. John Stirling Wood, William Stirling Wood, and James Robert Wood, 4, Stanley-street West, North Shields.

18501. Improvements in primary batteries. George Wallace and Wallace J. L. Sandy, 132, Coldharbour-lane, London.

18520. Improvements connected with coin-freed gas, electric, or other meters. Frederick John Beaumont, 173, Fleet-street, London.

18538. Improvements in wireless signalling systems. George Cecil Dymond, 6, Lord-street, Liverpool. (Gesellschaft für Drahtlose Telegraphie m. b. H., Germany.) (Complete specification.)

AUGUST 27.

18546. Improvements in electric incandescent lamps, whereby two or more lamps are governed by one central connecting cap or the like. Max Byng and William James Crawshaw, 71, Queen Victoria-street, London.

18561. Improvements in live rail protection for electric railways James Linkleter, Tyneside Works, Tynemouth.

18592. Improvements in electric railways. Edgar Alfred Carolan, 83. Cannon-street, London. (The General Electric Company, United States.)

18594. Improvements in galvanic batteries. Lothar Fiedler and Frederic Julius Gerard, 22, Southampton-buildings, Chancery-lane, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Sept. 15, 1904.

1903.

11828. Electric telegraphy. Muirhead.

11828a. Electric telegraphy. Muirhead. (Date applied for under Patents Rule 9, May 23, 1903.)

11921. Electric welding of turbine blades. De Ferranti.

17351. Electric railways. Westinghouse.

18318. Electric incandescent lamp. Wallace.

18354. Electromagnetic rail brakes. Wilde.

18624. Electric lamps of the character known as vapour lamps or vapour arc lamps. Bastian and Salisbury.

19657. Working of points and plough guides on electric or cable tramways or railways. Stewart.

20645. Arc lamps. Upton, Elliott, and Pratt.

22497. Electrical switch. Makin.

22634. Terminals for stranded electrical and other wires. De Veulle.

22981. Welding by electricity and apparatus therefor. Harmatta.

24626. Plates for secondary batteries. Thompson. (Pflüger Accumulatoren-Werke Actien-Gesellschaft.)

27736. Electrical means for starting prime movers for electric generators. Johnson. (Elektricitäts Aktien-Gesellschaft vorm. W. Lahmeyer und Co.)

1904.

5663. Annunciators for electric bells and the like. Henning.

8012. Line selectors of intercommunication telephone apparatus. Walloch. (Date applied for under International Convention, Sept. 25, 1903.)

8965. Section insulators for overhead trolley wires. Siemens Bros. and Co., Limited, Simpson, and Wheat.

9307. Alternating-current meters on Ferraris's principle. Morck.

12187. Telephone and telegraph systems. Ritter.

12691. Apparatus for the simultaneous transmission of telephonic and telegraphic or other currents over the same line. Turchi.

13427. Brake and means for suspension for overhead electrically-driven locomotives. Fairweather. (Brown Hoisting Machinery Company.)

13468. Electric switches. Scott. (Date applied for under International Convention, July 31, 1903.)

14066. High-voltage galvanic battery. Gournay.

15043. Electric telephonic transmitters and like instruments. Lake. (Submarine Signal Company.)

15283. Electric burglar and fire alarm. Ali.

15296. Electric elevators. Phillips. (Vogel.)

15699. Electrical resistances. Boehm.

15874. Electrical fire extinguisher. Ruppert.

15981. Telephone directories. Brownell.

16179. Electrical transformers. Peck and Fortescue. (Date applied for under International Convention, Aug. 8, 1903.)

16294. Electric lamp guards. Dickinson.

NOTES.

McMillan Memorial Fund.—The secretary of the Institution informs us that the subscriptions received to the 5th inst. amount to £1,709. 16s. 10d.—viz., members, £923. 1s. 4d.; associate members, £265. 3s.; associates, £262. 16s. 4d.; students, £52 1s. 3d.; foreign members, £24. 18s.; subscriptions from non-members, £181. 16s. 11d.—total, £1,709. 16s. 10d.

Society of Chemical Industry.—Sir William Ramsay presided on Wednesday at a banquet in New York, given under the auspices of the Society of Chemical Industry. The guests included the most celebrated American scientists. The American newspapers are paying generous tributes to Sir William's brilliant achievements. His successor as president of the society is Mr. William Nichols, of New York.

International Association of Municipal Electricians.—The ninth annual convention of this association will be held at St. Louis on the 13th and 14th inst. The Exhibition authorities are making great preparations, and several special electrical features have been arranged. For Thursday, Sept. 15, a joint session of this association and Section G of the congress has been fixed. This section is devoted to "electrical communication," and several papers of great interest will be read and discussed.

North-East Coast Institution of Engineers and Shipbuilders.—We have received a copy of this institution's *Transactions*, dated August, which contains a list of the papers read during the past session, the names of all the members, the constitution and by-laws of the institution, and memoirs of Messrs. J. Bulmer, W. T. Courtier-Dutton, S. Fox, J. Nixon, P. Salmon, A. G. Schaeffer, J. L. Thompson, and T. Whitfield. The twenty-first session will open early next month, and members are invited to present papers on a variety of specified subjects.

Municipal Tramways Association.—The second annual conference of this institution is to be held at Liverpool on the 27th inst. The list of papers includes "How to Effect Economy in Current Consumption," by Mr. P. Fisher; "Arrangement of Men's Duties," by Mr. J. B. Hamilton; "Methods of Dealing with Mixed Systems of Traction," by Mr. A. L. C. Fell; "Cars: their Equipment and Maintenance," by Mr. J. Aldworth; and "Overhead Equipment: its Construction and Maintenance," by Mr. J. M. McElroy. The Corporation of Liverpool has invited the members to dinner, so that with the association's banquet and an excursion it is evident that the social phase is not to be neglected.

Huddersfield's Enterprise. — The Corporation earned the distinction of pioneers in municipal tramways, and they have now inaugurated the system of coal haulage over the tramway lines to which we referred a few weeks ago. The idea is not by any means new, the Corporation having obtained the necessary powers as far back as 1880, and in America the cars have for years been utilised during the "small hours" for similar purposes; but until the advent of Mr. H. N. Thomas the project hung fire. The Corporation's late manager, however, interested himself in the subject, and the scheme has now arrived at fruition, the trial trip run last week proving quite successful. The Corporation have already entered into a seven years' contract with Messrs. Martin, Sons, and Co., Limited, a large manufacturing concern, to convey all the coal required by that firm. The slack hours of the morning will be utilised for this purpose, the afternoon being restricted to passenger traffic. This enterprise opens up an extensive vista of industrial possibilities. More details will be found in our editorial columns.

The Institution of Civil Engineers.—The council of the Institution of Civil Engineers have, in addition to the medals and prizes given for communications discussed at the meetings of the institution in the last session, made the following awards in respect of other papers dealt with in 1903-1904: Telford premiums to Arthur Hill, C.I.E. (Bombay), F. A. Hurley (Cairo), E. M. De Burgh (Greystones), H. H. Dare, M.E. (Sydney, N.S.W.), William Marriott (Melton Constable), T. G. Gribble (London), W. H. Haigh (Cardiff). For students' papers the awards are: a Millar scholarship, tenable for three years, and the James Forrest medal to C. W. L. Alexander, B.E., Birmingham; Miller prizes to J. M. Clark, M.A., B.Sc. (Glasgow), L. G. Crawford (Barrow-in-Furness), W. H. Dickenson, B.Sc. (Jesmond-on-Tyne), William Lawson (Newcastle-on-Tyne), C. G. Du Cane, B.A. (Middlesbrough), C. Gribble (York), J. E. Lister (Sheffield), J. M. Kennedy (London), H. Middleton (Newcastle-on-Tyne), J. D. Morgan (Handsworth).

New Publications.—In addition to the tenth edition of Prof. Jamieson's elementary manual on "Steam and the Steam-Engines," which we reviewed in our issue of July 1, we understand that Messrs. Chas. Griffith and Co. will bring out on Sept. 15 the sixth edition of the same author's manual on applied mechanics, which is a companion book to the former. They also hope to issue this month the fourteenth enlarged and thoroughly revised edition of Jamieson's text-book on "Steam and Steam-Engines," including steam turbines and boilers, and a seventeenth edition of Munro and Jamieson's pocket book of electrical rules and tables, with the submarine cable and other sections up to date. "The Engineering Telegraph Code," by Jas. Stevens (London: J. Stevens. 40s.) This is the second edition of this valuable work, which may claim to rank as a standard publication. The volume has been entirely rewritten, revised, and enlarged, and will doubtless continue to be of great service to engineers, manufacturers, merchants, contractors, and others.

Light Motorcar Trials.—The highly successful trials for small cars held by the Automobile Club came to a conclusion last Saturday evening, when 26 cars out of the 35 that started on the previous Monday morning finished the twelfth and last run between five and six o'clock. The judges have issued the following provisional list of non-stop awards: Class A (cost not to exceed £125), the 6-h.p. Speedwell, which did seven non-stop runs, was the only car in this section to qualify. No car qualified for the non-stop award in Class B (£125-£150). In Class C (£150-175), the 6-h.p. Siddeley gains first place with the full 12 runs. A pair of 6-h.p. Wolseleys, which ran as a team, and are judged on the average, came second, having performed 12 and 11 runs respectively; and a 6-h.p. Humber, with 11 runs, is placed third. The remaining cars which qualified in this section were a pair of 7-h.p. Alldays, a trio of 7-h.p. Star cars, a 6-h.p. Mobile, a 9-h.p. Speedwell, and a 9-h.p. Brown. In Class D (£175-£200) a 10-h.p. Croxsted gained the maximum score possible, a 7-h.p. Humber was second, and the team of 7-h.p. Alldays was placed third, the other cars to qualify in this division consisting of the team of Star cars, a 9-h.p. Mobile, and a 9-h.p. Anglian. In their final report the judges will make awards for excellence in design or construction.

A Japanese Power Plant.—An electric power plant has recently been installed at Iyo. The water power is provided by the rapids of the River Islute, the actual head approximating some 100ft., with a steady flow of about 50 cubic feet per second. Across the stream is placed a straight stone weir 132ft. long, which dams up the water

Digitized by Google

to a height of 4ft. from the canal bottom. The water enters the canal about 1,000 yards from the reservoir, which is located near the power-house. The present plant in the power-house comprises a waterwheel, supplied by J. M. Voith, Heidenheim, Germany, an electric generator, and a switchboard. The waterwheel develops 280 h.p. at 600 revolutions per minute, a suction pipe 15ft. long being used. Regulation of speed is accomplished by Voith's governor to within 3 per cent. The turbine is connected directly through a leather coupling to a three-phase generator of the revolving-field type, developing 260 kw. at 3,500 volts, the frequency being 60 periods per second when running at 600 revolutions per minute. The exciter is wound for 110 volts, and is placed on the same shaft as the generator. The three-phase transmission line consists of No. 3 B.W.G. wires, fixed to petticoat insulators. Telephone wires are also strung on the poles. Both the primary and secondary wires enter the transformer chamber, which contains two 10-kw. converters, by way of a vertical pipe 20ft. above the roof of the tower.

The Testing of Transformer Oil.—The usefulness of an oil as an insulation material is not determined by measurements of its insulation resistance, says the *Zeitschrift für Elektrotechnik*, but by measurements of the voltage required to break down a given thickness. A pair of polished balls should be supported at a fixed distance below the surface in a vessel containing about 200 cubic centimetres, and having a diameter about 3cm. The presence of water or air-bubbles or small fibres greatly affects the results obtained. For the purpose of determining the flashing point of the oil, a weighed quantity of it should be heated for about 12 hours in a water bath at 100deg. C., and the amount evaporated noted. The point at which steaming commences should be as high as possible, as the flashing point occurs at about the same temperature. The effect of water is so important, that the presence of only ·06 of 1 per cent. reduces the breakdown voltage by half. Further additions of water have little effect. The presence of water may be qualitatively determined by adding a little cupric sulphate to the oil. When free from water this sulphate is pure white, but becomes blue when in contact with water. A good transformer oil may be distinguished by the following properties: (1) it should be a pure mineral oil obtained from crude petroleum by frictional distillation without chemical treatment; (2) the flash-point should not be below 180deg. C., and the oil should not burn steadily under 200deg. C.; (3) the oil should be free from alkalies, moisture, or acids; (4) after being heated for eight hours the evaporation should not exceed ·2 of 1 per cent.; (5) the oil should be as fluid as possible, and should have a light-yellow colour.

Electric Lighting in Paris—For the purpose of electric lighting Paris is divided into sections, for each of which the City Council granted a concession to a different company. These concessions begin to expire in 1907, and the Council is not disposed to renew them on the old terms, there being a strong tendency towards municipalisation. A few years ago the city authorities unsuccessfully endeavoured to negotiate with the electric light companies, and it is now necessary to come to an early decision on the subject. The question of the city taking over the electric lighting concessions is somewhat complicated. The various conduits and "canalisations," extending over some 400 miles, made by the electric companies to carry their wires and cables become, by the terms of the agreement, the property of the city at the expiration of the present concessions. On the other hand, the generating stations and sub-stations, and the connecting wires to the consumers remain the property of the companies, who are not obliged to sell, though it is certain that the authorities would refuse permission to construct fresh conduits. With the question of the gas supply on their hands the City Fathers have had little time hitherto for looking into the subject of electric lighting, but a technical committee has now been appointed to consider the matter. It is expected in some quarters that, unless the Council desires to spend a large sum on new plant, the matter will be compromised by a renewal of the concessions upon enhanced terms; but the Council appears to be in a strong position for forcing, if so disposed, the hands of the companies in relation to the sale of their generating stations and connecting wires.

A New Controller Regulator.—An invention has recently been patented by Mr. S. W. Williams, of Michigan, for the automatic regulation of street car controllers when the vehicles are being accelerated, some particulars of which are given in the *Street Railway Journal* of New York. The object of the device is to so limit the operation of the controller handle as to prevent its being thrown around from the series starting notches into the parallel position so quickly as to start the car with a shock or jerking, and at the same time permit the propulsion current to be thrown off the motors instantly. A mechanism interposed between the operating handle and the car controller staff accomplishes this, the handle being so restricted in its forward movement by an arrangement of ratchets and pawls that the motorman cannot possibly throw the power on fully at once. The mechanism permits him to throw the current on to the motors a notch at a time, a considerable delay between notches being made compulsory by the mechanism to permit the motors to accelerate properly. If, however, it is found desirable to throw off the current instantly, the arrangement of ratchets is such as to permit this to be done in the usual manner. Additional features are incorporated in the regulator which permit the controller to be instantly reversed and thrown on to the third reverse notch in case of impending danger. This is a very valuable provision, as in emergency stops the first or second notch of the controller is not sufficiently effective. An additional precaution provided for in this mechanism is that for locking the controller when it is desired to leave the car temporarily. This is very simply provided for in connection with the regulator mechanism.

The New Patent Regulations.—Some comments on the order just issued by the Board of Trade bringing into force as from Jan. 1 next the system of examination of patents embodied in the Act of 1902, and reducing the period of provisional protection from nine to six months, have been received by us from Messrs. W. P. Thompson and Co, patent agents, who have devoted considerable attention to legislation of this character. They remark that the system of examination thus instituted is much less perfect than those of other countries, as the examiner has merely to search through the British patents of the immediately preceding 50 years to see if in these there be in his opinion any anticipation of the invention set forth in the complete specification. This report is forwarded to the comptroller, and if the comptroller be of the opinion (from this report) that the invention is partly or wholly anticipated, the applicant is informed of the anticipation, and has the option of a personal hearing or of amending the specification to the satisfaction of the comptroller, or, in default of either, the comptroller determines whether a reference to any, and if so, what prior specifications must be made in the specification by way of notice to the public. Against his decision there will be an appeal to the Law Officer. The examiner's report will be kept strictly secret from all but the applicant and his agent, but this examination must not

Digitized by Google

be held in the slightest to guarantee in any way the novelty of the invention or the validity of the patent, as, of course, the prior publication of the invention in other documents open to the public in England prior to the date of the application, or the prior public use of the invention, would be equally as fatal to the validity of the patent as the publication of the invention in a prior British specification.

Manchester Municipal School of Technology.—The Manchester Municipal School of Technology has issued, in a tolerably bulky volume, its syllabus for the session 1904-5, the description of the various courses being preceded by a statement of the object of the school. In this it is pointed out that the successful career of a student depends very largely upon his previous education, for unless this has been thorough and liberal no satisfactory progress can be attained in any of the departments of the school. It is impossible to obtain full benefit from the courses of instruction unless the student has mastered the fundamental principles by adequate previous preparation. The courses of instruction are directed more especially to the requirements of the industries of South-East Lancashire, of which Manchester is the commercial centre. To day students who have reached their sixteenth year the school offers courses, each of three years' duration, in mechanical engineering, electrical engineering and technical physics, municipal and sanitary engineering, general and industrial chemistry—general technical chemistry, bleaching, dyeing, printing, and finishing of textiles, manufacture of paper, brewing, metallurgy; manufacture of textiles, photography, and the printing crafts and architecture and the building trades. There is besides a special day course for selected apprentices in the employ of engineering firms. Students are required to pass an entrance examination in subjects of general knowledge. As at present arranged, the diploma of the school will be awarded to those students who have satisfactorily fulfilled and complied with the conditions of the three years' course in any of the above-named departments. The school also offers to evening students systematic courses of technical instruction, and training in all the chief and in many of the minor industries of the city and district. The day session will commence on the 19th inst. and the evening lectures on the 26th inst.

New School of Metallurgy.—The School of Metallurgy at Bournbrook, in connection with the Birmingham University, was formally opened on Monday afternoon. The erection of the building cost £10,000. Prof. J. Turner, in the course of his address, observed that there was no more ready index to the progress of civilisation in any nation than that afforded by the knowledge of the worth and value of its metallurgical products; and it was of the utmost importance that our metallurgical industries should be encouraged and developed, if Great Britain was to keep her position amongst the nations of the world. England used to be spoken of as the chief coal and iron producer of the world, and the country occupied a prominent position as a producer of other metals. We still led in gold, because of the Transvaal and Australia; but we were now second in coal, third in iron, fifth or sixth in other metals, and we only produced about one-twentieth part of the world's output of tin, lead, and zinc. Our two chief competitors had been the United States and Germany, and the reasons for their progress were varied. In America we had the necessities of a new country, the rapid development of its railways, the opening up of enormous fields of ore deposits and coalfields. Having briefly alluded to the question of tariffs, the professor dealt with the influence of education on metallurgical progress and the lines we should follow in order to obtain the best results. He mentioned what was being done in America and Germany, and said that at Birmingham two styles of training had been recommended—that adopted by Dr. Percy at the Royal School of Mining and the one in vogue at the newer schools of mining and metallurgy in America. The older schools of metallurgy were either too exclusively theoretical or too exclusively practical. At Bournbrook they would combine theory with practice. Students would analyse their ore, decide which was the best process of extraction, and then extract the ore. No course so ambitious had been attempted in England before, and he was quite sure they would get some useful experience from it.

Dundee.—Previous references have been made in these columns to the proposals of a London syndicate for the supply of energy for motive purposes, and the borough electrical engineer, Mr. H. Richardson, has just issued his report upon the question of whether it would be advisable for the Corporation to give their consent to the scheme. Mr. Richardson prefaces his views with the remark that the millowners have never approached the Corporation for the supply of energy in bulk at special rates, although on no occasion have the authorities intimated that they would decline such an application. The report proceeds to state that, whether the company are allowed to come into Dundee or not, the Town Council will in the near future have, in consequence of the increase of business, to face the erection of a new power station on a different site. The space under the pavement of the streets is so much taken up with town's property that it would be impossible to make room for a company's cables, and under the agreement formulated by the company the Corporation would be deprived of all profitable work, and would be handicapped by being forced to supply unprofitable loads which the company refused to take. Besides this, there is the probability of electrolytic troubles due to leakages from the two systems, and these would constitute a very serious inconvenience and danger. As regards the charges, Mr. Richardson points out that the Corporation was already in a position to reduce the price of current for power purposes, and a reduction was only being delayed until a sliding scale had been decided upon. The company's charges had been put forth at about $\frac{7}{8}$d. per unit, but this charge would be made only in exceptional cases, the real prices which the company said they were going to charge varying from 1$\frac{1}{2}$d. down to $\frac{7}{8}$d. The only scheme which he could advise the Council not to oppose would be one under which the company should start their supply at 5 a.m. and shut down at 6 p.m. promptly, no system of storage being permitted in connection with any consumer's plant, thus restricting the syndicate to the object first announced by them—the supply of energy for mills only.

Trade Marks in China.—Some weeks ago we referred to the important treaty entered into between Great Britain and China, by which the latter undertakes to establish divisional offices for the registration of patents, attention to which was directed by Messrs. W. P. Thompson and Co., patent agents. These gentlemen now state that, from advices just to hand, they learn that the regulations for carrying the undertaking into effect have been officially published. The British Government has assented to them, and the Japanese Government raises no objection, so that the regulations will no doubt be put into force if they are assented to by the United States Government. Briefly, the regulations are as follows: Any person desiring to use a trade mark in China must first register the same according to these regulations. The Board of Commerce shall establish a bureau of registration. Every application must contain a statement giving a general description of the trade mark, the class and particular kind of goods for

Digitized by Google

which it is to be used. The application will be placed on file for three months and advertised by the bureau, and if no one petitions against it, it will be registered. If two persons apply for similar trade marks, the first applicant will receive registration, but in the case of a trade mark already registered in a foreign country, the date of such foreign registration will be recognised if application in China be made within four months. During the first six months of the establishment of the bureau, applications can be made for registration of trade marks already registered abroad, and the bureau shall recognise such trade marks as entitled to precedence. Any mark which has been publicly applied in China to a special article for more than two years before application for registration, cannot be registered. Suits for infringement by foreigners against Chinese are tried by a local magistrate and the consul sitting together, but if both parties to the suit be foreigners, the consular court has jurisdiction. Penalties for infringement are very severe. It is believed that the new treaty will prove very useful, as trade marks that are registered will be more efficaciously protected from infringement, but omission to register may involve loss of rights.

Revised Board of Trade Regulations.—In our issue of the 26th ult. we alluded briefly to the drafts of new regulations issued by the Board of Trade governing the supply of electrical energy, to supersede those promulgated in 1896, the Board being of opinion that the experience which has been gained during that period renders a revision desirable. The regulations are classified according to the character of the undertaking, as mentioned in our previous notice. The general trend of the proposed alterations is in the direction of greater liberality. In regard to pressures, the distinction between alternating and continuous current has been abandoned, and the following four standards have now been fixed for either type: low pressure, up to 250 volts; medium pressure, from 250 to 650 volts; high pressure, from 650 to 3,000 volts; and extra high pressure, exceeding 3,000 volts. Hitherto it has been necessary to obtain the express permission of the Board before supplying current at the consumer's terminals at any pressure greater than 250 volts; but now, on the consumer undertaking to observe reasonable precautions, such as earthing the frame of the motor, laying wires in earthed metal casing as far as possible, and providing suitable switches and protective devices, he may be supplied at any pressure up to 650 volts for such purposes as motor driving or series arc or incandescent lighting. A notice is also required to be fixed at every motor switchboard and motor, forbidding unauthorised persons to touch the apparatus. Special permission must be obtained for the introduction of medium pressures into consumers' premises for other purposes than those abovementioned, as well as for the introduction of high pressures. Extra high pressures may be supplied to factories, mines, and traction works, subject to the consent of the Board and the provisions of the Factory Acts and Mines Regulation Acts. In other respects the proposed new regulations do not materially differ from the existing ones. They are distinctly rational in character, and may be expected to exercise a beneficial effect upon the service and the industry. A code that is immutable as the laws of the Medes and Persians is obviously open to drawbacks; and a judicious provision has been inserted empowering the Board to vary the regulations under special circumstances.

Electricity in India.—The applications of electric power in the mill industries of India—jute and cotton—have not as yet, remarks the *Indian and Eastern Engineer*, reached that stage of development (which, however, we may before long anticipate) when the advantages of electricity will have generally supplanted the old type of transmission gear for the main mill drives, but it is being extensively adopted as an auxiliary for light and small power purposes, such as fans for offices and small motors for pumping purposes. Our contemporary gives some particulars concerning a plant of this description recently installed by Messrs. Burn and Co., of Howrah and Calcutta (whom, we note, have a number of Indian electrical contracts for various purposes in hand), for the Kankinarrah jute mills. This plant consists of three sets, the engines being of the Bellis-Morcom enclosed type, direct coupled to three generators made by the Clayton Engineering Company, each capable of dealing with 500 16-c.p. lamps at 225 volts pressure, or of supplying the equivalent amount of energy for other purposes. Steam is supplied to the engines at 160lb. pressure, but the cylinders are provided of sufficient area to enable the dynamos to supply full current at 126lb. pressure, an elasticity of generating power which is of great value under a variable load on the main boilers. All switches, measuring instruments, and cut-outs are mounted on marble slabs 1in. thick, polished and mounted in polished teakwood mouldings set 2ft. away from the wall, each end forming a hinged door so as to enable inspection and addition at the back of the board. Three circuit breakers are provided and adjusted to release with 10 per cent. overload. This pattern of circuit breakers is specially designed for switchboard work, and is so constructed as not only to release at the set current, but should the circuit be overloaded, it cannot be held closed. All the positive leads are taken to the left-hand side, and the negative to the right-hand side of the board. The circuit breakers are constructed so as to be a switch and circuit breaker combined. The three voltmeters are on the right-hand side, and the three ammeters on the left-hand side, all permanently in circuit with their own machines. The switchboard is so arranged that all the three engines can be run in parallel to supply all the light required during the evening in the mill and compound and bungalows, or if only part of the light is required, two engines only are worked, and during the day one engine only is run for the fans in the bungalows, offices, etc. All outside lights in the compound are of 32 c.p., and are in watertight pendants. The fans supplied consist of 28 of Messrs. Burn and Co.'s standard improved pattern, which are specially designed to run cool, and consume a small current. The armature is of considerable size—6½in. in diameter—drum wound on a hollow frame, and thus excellent ventilation is provided for. There are six field-magnet coils, all series wound, and the bearings are all self-aligning, and are automatically lubricated. The commutator is of extra large dimensions—2in. in diameter—formed of hard-drawn copper bars insulated with mica, and large carbon brushes are held by spiral springs against the commutator. The general arrangements allow of any extensions being provided with a minimum of disturbance to the existing plant.

Underground Temperatures. — At the recent meeting of the British Association at Cambridge the several distinguished scientists appointed to the Committee for Investigating the Rate of Increase of Underground Temperatures Downwards in Various Localities of Dry Land and under Water presented their twenty-third report. The investigations cover a wide area, and the report, in merely abstract form, extends over several pages, so we propose to briefly recapitulate some of the results. A preliminary report respecting the Calumet and Hecla mine puts the rate of increase at 1deg. F. in 120ft. to 130ft. Two of the Bendigo gold mines were tested, at depths of 3,000ft. and 3,645ft. respectively, each showing an increase

Digitized by Google

at the rate of 1deg. in 80ft. The mean surface temperature inferred from observations at 182ft. and 247ft. in neighbouring shallow shafts was 61·4deg. Electric resistance platinum thermometers were used in this instance. Tests on mines at Ballarat, Maldon, and Port Jackson yielded very similar results. A shaft, some 3,300ft. deep, was recently sunk at the collieries of Rouchamp, in the eastern division of France, and investigations showed the increase in rock temperature to work out at the rate of 1deg. in 46ft. Regular observations have been taken in the Simplon Tunnel, and on its completion, which is imminent, the results will be at once communicated to one of the London societies. The recently published report of the Royal Commission on Coal Supplies, which contains a quantity of evidence on temperatures in deep coal-mines, is dealt with at some length. At the Rams mine, Pendleton, the temperature at 3,483ft. below the surface was found to be 100deg., showing an increase of 53deg. over the surface temperature, or 1deg. in 66ft. At the Agecroft Colliery, in the same district, the deepest observation was made at 2,940ft., where the temperature was found to be 92 5deg., showing an increase of 1deg. in 65ft. In the North Staffordshire coalfield, Mr. W. N. Atkinson, H.M. inspector of mines, found the following temperatures at the greatest depths reached: Sneyd Colliery, Burslem, 87 5deg. at 2,625ft.; Glebe Colliery, 83½deg. at 2,295ft.; Great Fenton Colliery, 85deg. at 2,400ft. Assuming 48deg as the surface temperature, the mean rates of increase are: Sneyd, 1deg. in 66·5ft.; Glebe, 1deg. in 65·1ft.; Great Fenton, 1deg. in 64·9ft. The method of observation was to drill a hole, insert a bottle of water, and after leaving it in the hole, plugged with clay, for 24 hours or more, take it out, and put a thermometer into the water in the bottle. In the Sneyd Colliery observations were thus taken at 13 depths during the sinking of a shaft, beginning with 1,104ft. and ending with 2,625ft., and the increase shown was fairly regular. The Glebe and Great Fenton observations were also in sinking shafts. Tests made in other mines show large variations, the increase of temperature in the case of the Hamstead Colliery in South Staffordshire amounting to no more than 1deg. in 110ft. Prof. H. Höfer, of Austria, has recently issued a circular recommending for temperature observations during the sinking of mining shafts the use of maximum thermometers divided to fifths of a degree Centigrade, to be inserted in holes bored to the depth of at least 2m. in the floor or side, and well plugged. The observations are to begin at 25m. from the surface, to be repeated at intervals of 50m. till a coal seam is approached, and then at shorter intervals through and a little beyond the seam. This process is to be repeated for every seam that is traversed. A main purpose of such investigation is to determine the influence of coal seams on the temperature of their surroundings.

The Poulsen Telegraphone. — In our issue of April 26, 1901, we gave a description of an electromagnetic phonograph, termed the "Telegraphone," designed to record and audibly reproduce telephone messages, the apparatus being the invention of a Danish engineer, Mr. V. Poulsen. Since its inception the inventor has been engaged in improving the device, and a syndicate has been formed at Copenhagen for its exploitation. Some new facts relating to the system are communicated to the *American Telephone Journal* by Dr. A. Gradenwitz. The principle on which the apparatus is constructed is indicated by the following description: On a cylinder is wound a steel wire or band, running in front of the poles of an electromagnet, to the poles of which a microphone is connected. On speaking into the microphone, induced currents produce continuous variations in the field strength of the electromagnet and coils, causing changes in the magnetism produced by the latter in the steel wire. This magnetism is permanent, and serves to register language. Reproductions are made by the steel wire bearing the electromagnetic record being drawn along before the poles of a similar electromagnet inserted into the circuit of a telephone, so that the process will be repeated in inverted order, acoustic vibrations analogous to the original vibrations being produced in the telephone membrane. Considerable loss in the language currents was found to result from the imperfect utilisation of the lines of force of the record in the process of reproduction. In order to obtain effects as satisfactory as possible, the pole of the iron core is entirely covered by the windings, as shown in

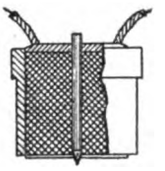

FIG. 1.

Fig. 1. The records may be reproduced more than 10,000 times without any diminution in the intensity being noted; though, on the other hand, they may be easily erased by a comparatively strong magnetisation of the whole record material. The record may be transmitted to another record material, yielding a somewhat weaker copy. About a year ago the inventor tried, with excellent results, a form of record material similar to that used in mechanical phonographs, but in the latest type of apparatus the steel cylinders are replaced by thin steel plates, the latter being cheaper and more convenient. These steel plates are susceptible of receiving records on both sides, and their dimensions permit of them being sent anywhere through the post, in order to be reproduced on a similar apparatus. Among other purposes, the telegraphone has been used to give and receive messages by telephone in the absence of one of the parties. This has been done between New York and Washington, the reproduction being quite distinct, notwithstanding the distance. Plate apparatus, with greater plates capable of stronger acoustic effects, are expected by the inventor to be of use for instruction in language, singing, and rhetoric, the voice being reproduced in natural tones instead of the peculiar accents noticed in the ordinary phonograph. The telegraphone has also been used to record wireless telegraphy dispatches, though the results so far obtained have not been very satisfactory. A special application of the telegraphone is known as the "telephone newspaper," being an apparatus by means of which a speech, song, etc., may be distributed to any number of people. An endless steel band is laid round two rotating

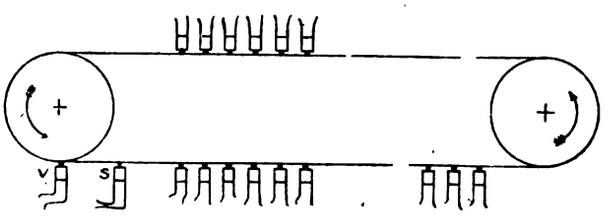

FIG. 2.

discs, as shown in Fig. 2, and these discs draw the band before an electromagnet that records the news. The discs are afterwards carried before a large number of "reading magnets," arranged in a long series, one behind the other, each being in connection with a different telephone line. The record band eventually passes in front of an obliterating magnet, V, whence it again passes before the recording magnet, and so on.

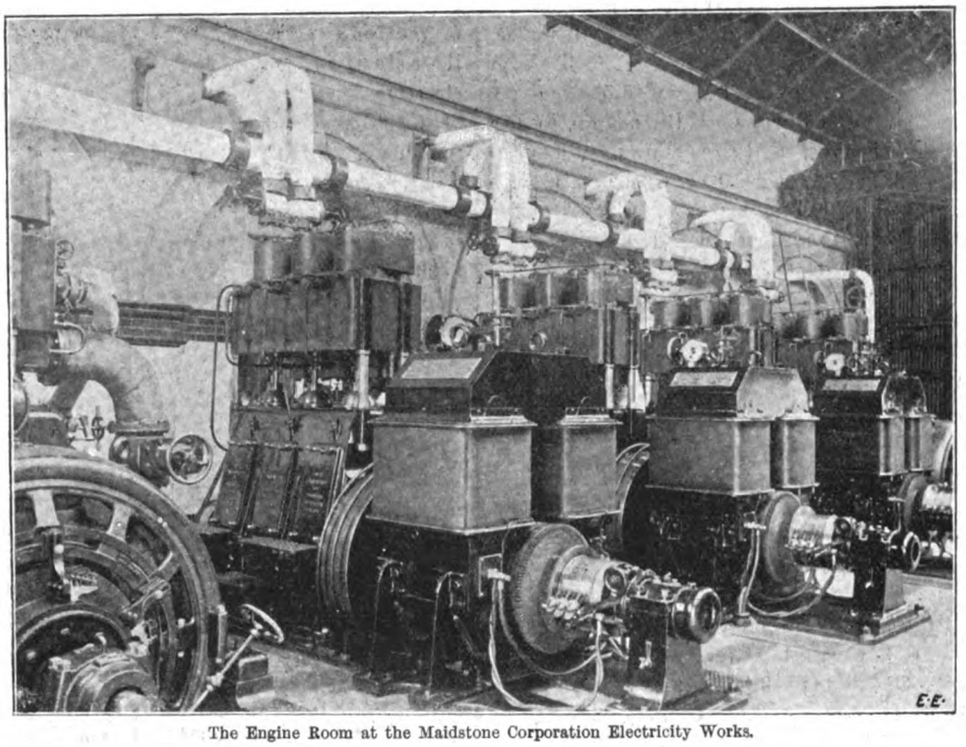
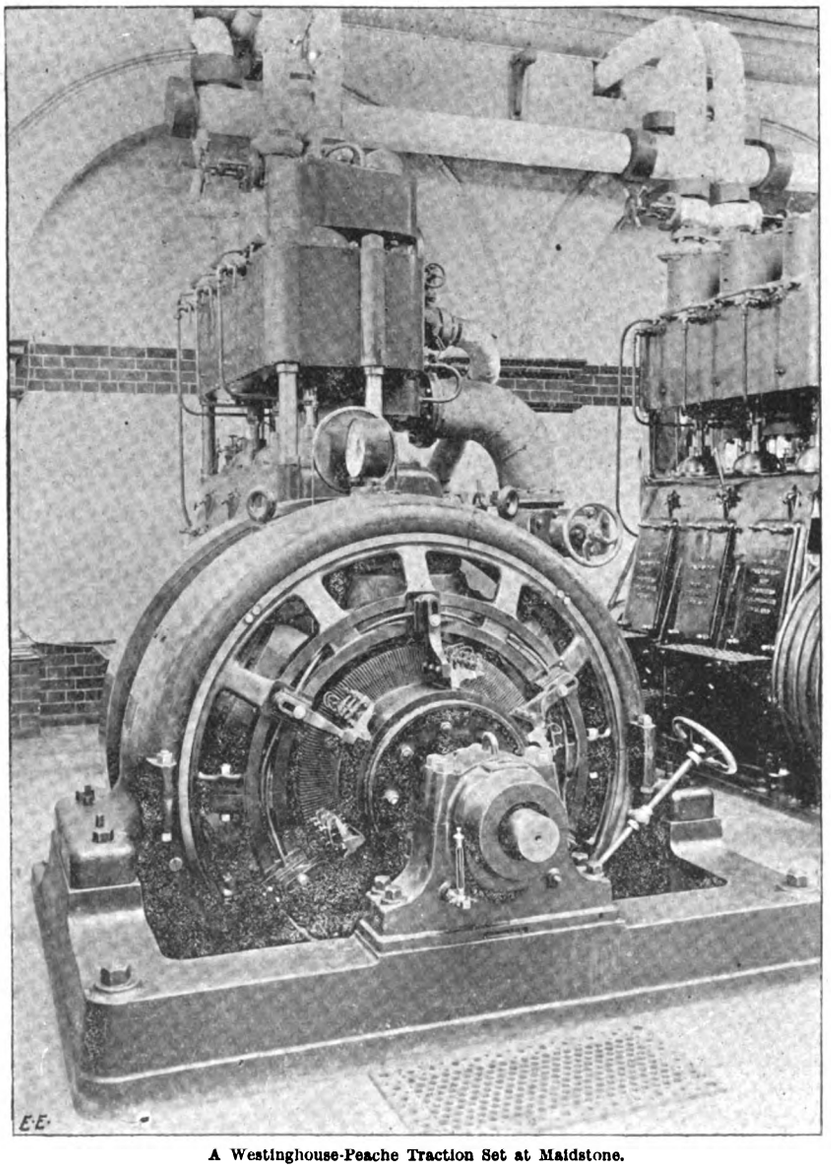
MAIDSTONE ELECTRIC TRAMWAYS.



The Engine Room at the Maidstone Corporation Electricity Works.

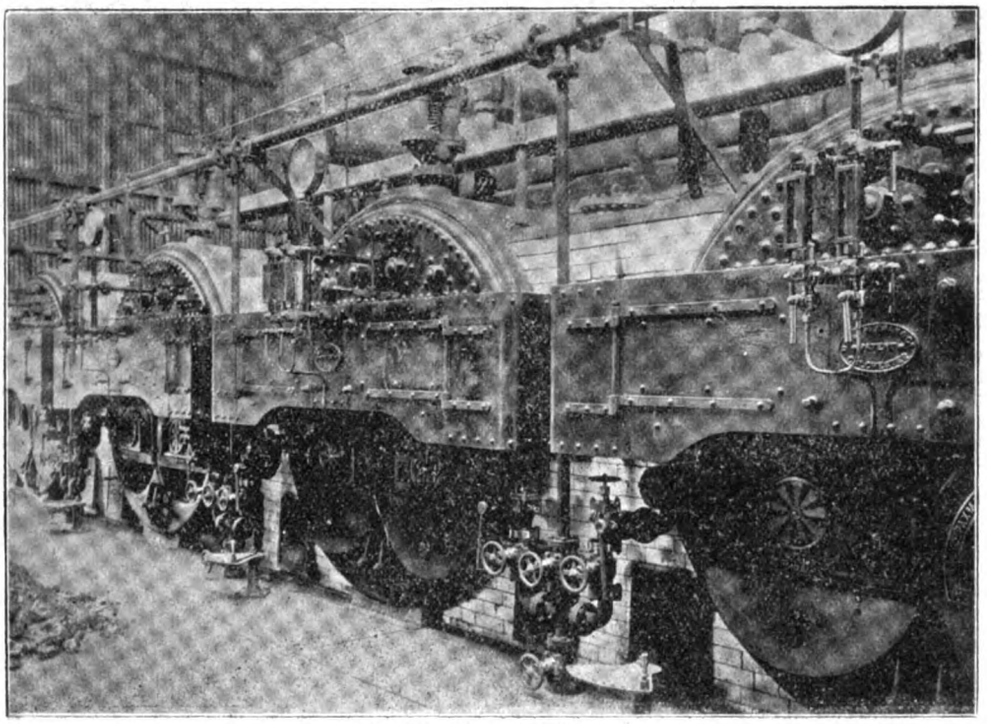


A Westinghouse-Peache Traction Set at Maidstone.

The chief town of Kent is noted for the keenness displayed by its inhabitants in things municipal and for the opposition with which any innovation is met. It speaks volumes, therefore, for the Committee, who are

Digitized by Google

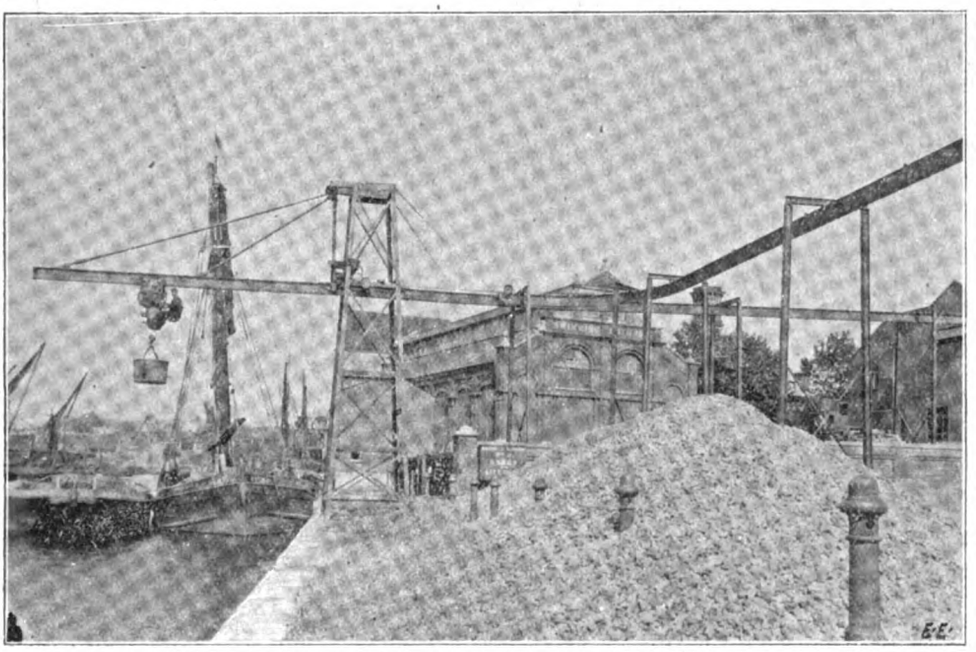
responsible for the introduction of electric traction in Maidstone, that they have succeeded in carrying through their scheme to a successful issue. The opponents of the scheme were unkind enough to say that the destinations of the three lines first to be constructed were emblematical of the policy of the Tramway Committee. As an explanation is needed to those of our readers not well acquainted with Maidstone, we may add that the workhouse is near the terminus of the one line, the second passes by a lunatic asylum, while the third goes to the cemetery. We may be quite sure, however, that the opponents of the tramway system will be amongst the first to support it when they find what a convenience it is, and they may perhaps remember that it was the opposition to the introduction of railways which caused the main lines to leave Maidstone on one side of their fast routes.



The Boiler House at Maidstone.

The power required for driving the tramways is supplied by the Corporation's electricity works in Fair Meadow, which were described in our issue of Jan. 3, 1902. These works were opened in December, 1901, the plant then installed being as follows; four Economic multitubular boilers made by Davey, Paxman, and Co., Limited, each capable of evaporating 6,000lb. of water per hour at a working pressure of 160lb. per square inch; four Peache three-crank compound single-acting engines of 250 h.p. each and one of 125 h.p., direct coupled to shunt-wound bipolar dynamos by Thos. Parker, Limited, and of a total capacity of 675 kw.; condenser by Cole, Marchant, and Morley, capacity 18,000lb. of steam per hour at 26in. vacuum—circulating water is obtained from the River Medway, about 50 yards distant; two Chloride batteries of 140 cells each, and of 400 ampere-hours capacity; switchboard by Messrs. Kelvin and James White.

Since 1901 several important extensions have been carried out—viz., an overhead electric conveyor has been erected, which is arranged to unload coal from barges on the river and deliver it direct into a new coal store which has been constructed at the side of the boiler-house. A branch track is also provided parallel to the river, and the conveyor can be used on this for unloading road metal for the highways department. One of Messrs. Paterson's patent grease separators has been installed for purifying the con-



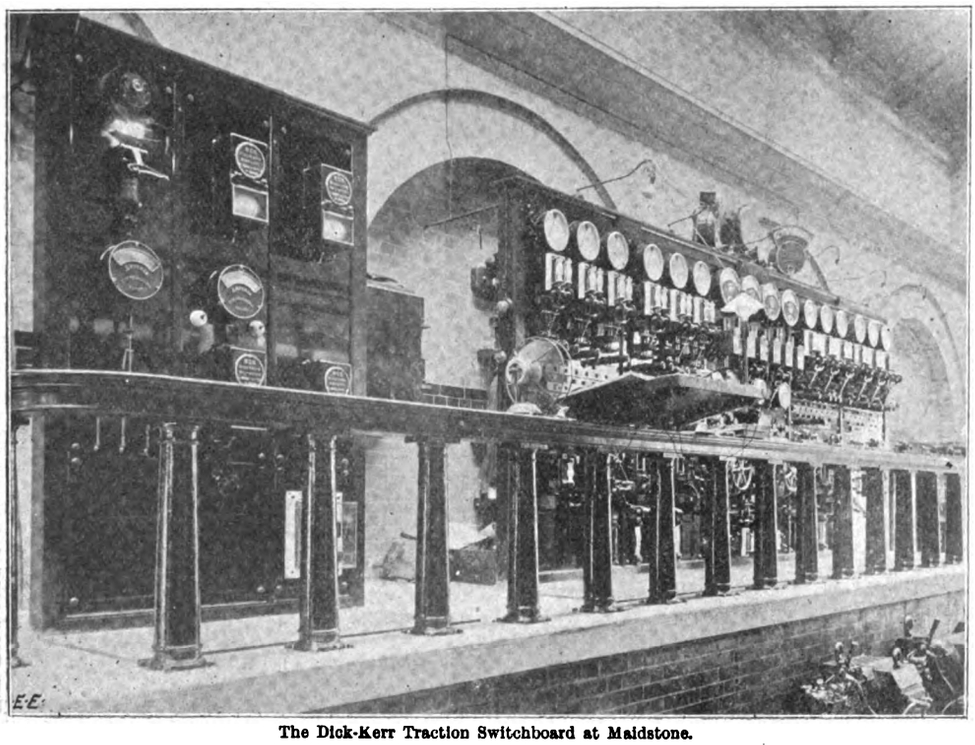
Overhead Electric Coal Conveyor at the Maidstone Electricity Works.

Digitized by Google

densed steam to enable it to be used for boiler feed, and any make-up water required is treated in a water softener made by the same firm.

In order to provide power for the tramways, the 75-kw. set was changed for one of 150 kw., consisting of a Peache engine direct coupled to a compound-wound dynamo of the British Westinghouse Company's manufacture. The existing dynamos being all shunt wound, and it being advisable to have a duplicate set available for traction purposes, another Westinghouse machine was substituted for the 150-kw. Parker dynamo on the No. 5 engine, and a heavier flywheel was fitted. Switches are provided on these machines for cutting out the series winding, and the leads from both dynamos are taken to the lighting switchboard, where by an arrangement of plugs they can be run on either the lighting or traction 'bus bars. Maximum and reverse current circuit breakers are fitted on the positive side of each machine, and 300-ampere knife switches on the negative poles.

The switchboard gallery has been extended, and a three-panel traction board by Messrs. Dick, Kerr, and Co. erected at a sufficient distance from the lighting board to allow for another feeder panel being added to the latter. At present there is only one feeder on the traction board for the line and one for return. The instruments on the line panel comprise a 300-ampere magnetic blow-out circuit breaker, one 300-ampere meter, one 300-ampere knife switch, and fuses for voltmeters and recording wattmeters. The Board of Trade panel contains a 5–0–5 recording ammeter, line leakage testing ammeter, and rail-drop recording voltmeter. On the negative panel are a recording voltmeter and a recording ammeter (N.C.S.), and a B.T.H. watt-hour meter. A subway has been constructed leading from the chamber under the switchboards to the street, and this will greatly facilitate the bringing in of any new cables.



The Dick-Kerr Traction Switchboard at Maidstone.

One of the Maidstone Tramcars.

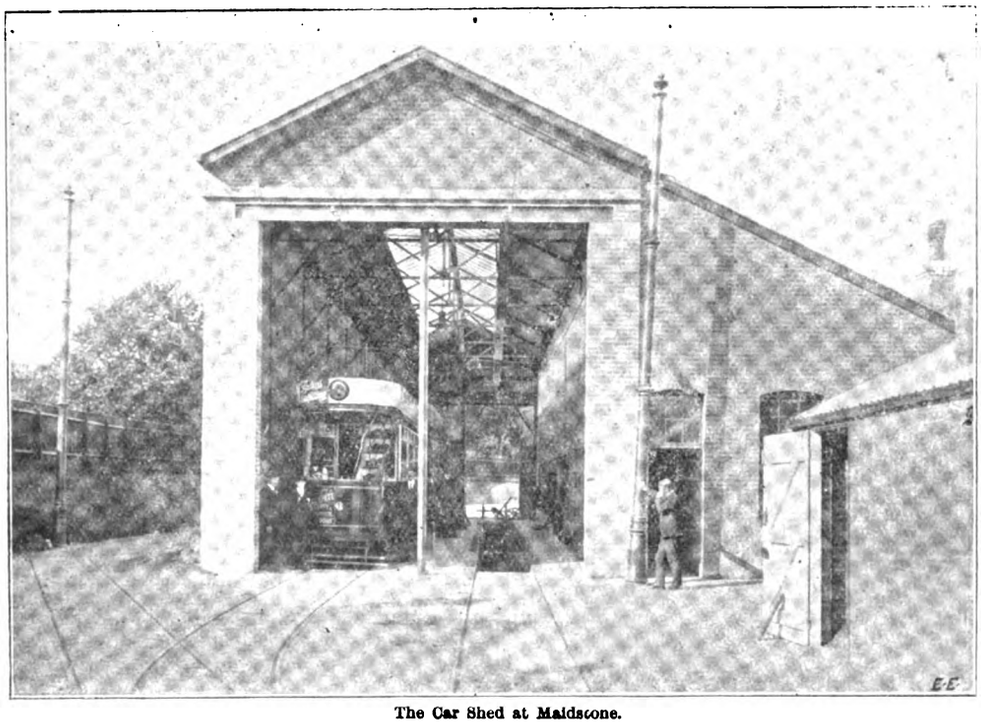
For the tramway itself the main contract was placed with Messrs. Dick, Kerr, and Co., and include the permanent way, overhead equipment, cars, and car-shed, and an addition to the switchboard. The route length of the permanent way is just over two miles, and is of single track with

Digitized by Google

passing places throughout. The gauge of the line is 3ft. 6in. The form of construction adopted is as follows: The portion of track within the town proper is paved with 9in. by 3in. hardwood blocks, and for a part of the length where the gradient approaches 1 in 15 the track has been paved with 5in. by 4in. granite setts. The remainder of the track, amounting to about one mile, in the outlying portion of the town, where the traffic is slight, has been paved with a serration of granite on either side of the rails, with macadam filling in between, this form of construction lending itself particularly well to roads subjected to light traffic, and is, of course, particularly favourable upon grounds of economy. The points are in accordance with the latest practice, and are 13ft. long over all, of the extended leg type, the tongues, which are 8ft. 6in. in length, being specially spiralised in order to give the cars easy entrance to the loops. In connection with the granite serration and macadam paving, the concrete bed has been put in to the full width of the tramway formation to provide for paving the track throughout at a later date, should the Corporation decide to do so. The rails used are the British standard No. 2 section, weighing 95lb. per yard. The joints are of the "Dicker" type, fixed by 6in. bolts fitted with the Eureka lock. Tie-bars are spaced at 6ft. centres, and are of the patent rolled weldless type. The track has been bonded throughout with 4/0 Neptune bonds. In addition to the track work, widenings have to be carried out at three points along the route, amounting in all to 700 yards of route. The overhead equipment is on the span-wire system, and is of a particularly neat and rigid construction.

Overhead Work, Maidstone.

The cars, of which there are six, are double-deck, single-truck, and are built to run on a gauge of 3ft. 6in. They have all the very latest improvements, and are similar to the cars recently supplied to the Leicester Corporation, and were built for Dick, Kerr, and Co. by the Electric Railway and Tramways Carriage Works, Limited, of Preston. Each of the six cars has a seating capacity of 48 persons—22 inside and 26 outside—and is supplied with a complete electrical equipment. The motors are Dick-



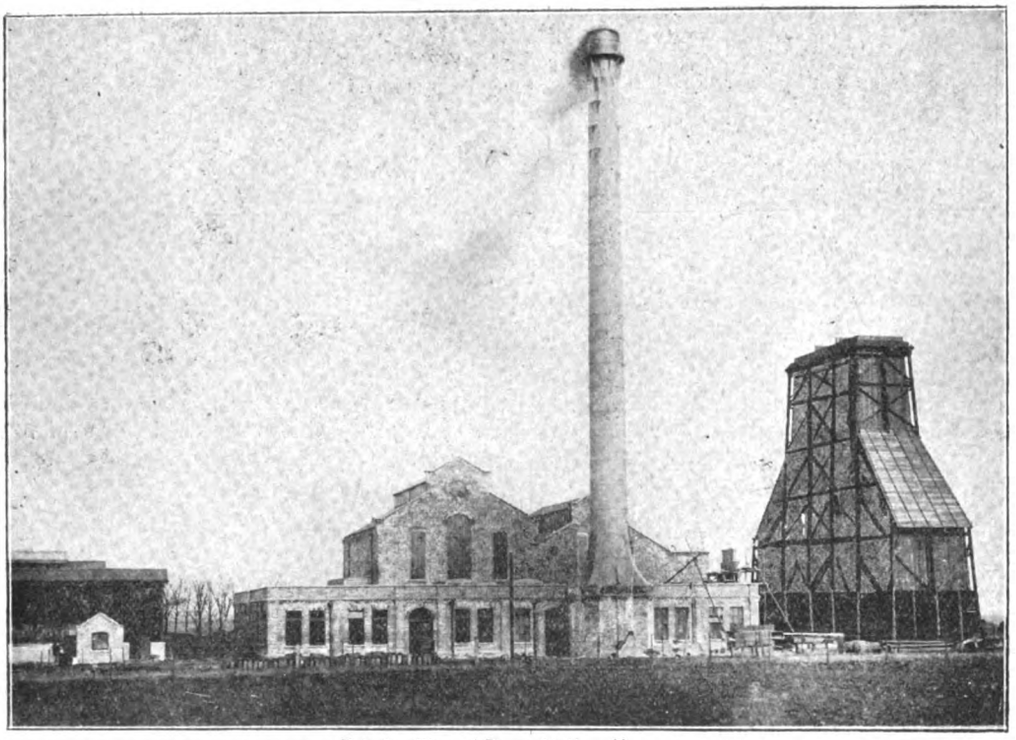
The Car Shed at Maidstone.

Digitized by Google

Kerr's standard 25 B type, 500 volts, and will deliver approximately 28 h.p. at the armature shaft, based upon the standard rating—*i.e.*, a rise in temperature of not more than 75deg. C. in its various parts after running at a full load for one hour. The equipments are mounted on Brill 21 E trucks. The controllers supplied with the electrical equipments are Dick-Kerr's standard D.B.I. form, C type, especially arranged with resistances for rheostatic braking, operated by the driving handle, which may be utilised either when the car is proceeding backwards or forwards.

The car-shed has been built to accommodate six double-deck cars, and has been constructed with a view to rapid and economical extension. The building is generally of brick, but the east wall, on which side the extension will probably be made, is panelled with 9in. brickwork between steel stanchions carrying the roof principals. The roof has been covered with 5in. pitch galvanised iron, provision being made for the substitution of slate should this be decided upon at a later date. The main shed proper contains pit accommodation for four cars. Provision has also been made for offices and stores, also paint and work shops for repairing the cars.

The whole of the work has been designed and carried out to the satisfaction of Mr. E. E. Hoadley, the borough electrical engineer of Maidstone. The engine foundations, steam and exhaust pipes, cables, and cablelaying within the station have all been carried out by the Corporation's own staff. The tramway load will be of great service to the undertaking, but we are pleased to know that by energetic management Mr. Hoadley has also obtained a good motor load which for a non-manufacturing town like Maidstone is exceptional.



Exterior View of Power Station, Sheerness.

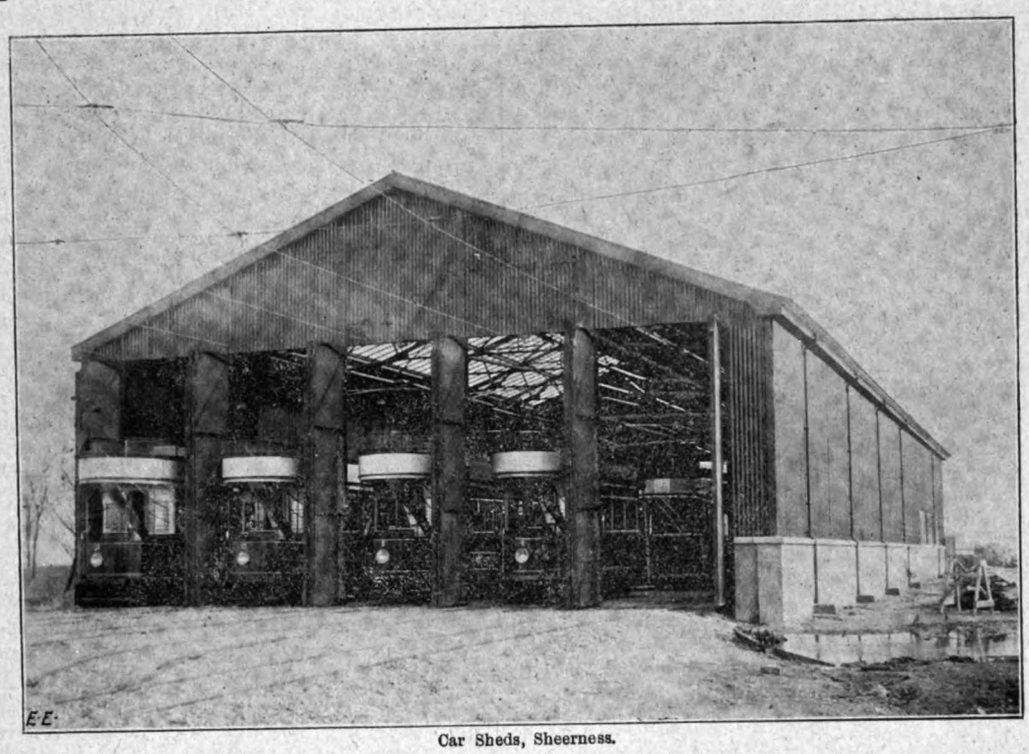
THE ELECTRIC LIGHTING AND TRACTION UNDERTAKING AT SHEERNESS-ON-SEA.

The supply for lighting and traction purposes of the Sheerness and District Electric Power and Traction Company was started in April, 1903. The provisional order was obtained in 1900, and on October, 1902, building operations were commenced. Sheerness numbers about 18,000 inhabitants, mostly connected with the naval dockyard, where some 4,000 workmen find employment. The line starts at the dockyard railway station, runs along the dockyard entrance gates and the passenger station of the South-Eastern and Chatham Railway, through the principal business street of the borough, up to the Sheerness East Station of the Sheppey Light Railway, about one mile outside the town. There are possibilities of a remunerative traffic during the summer months from the trippers going to Leysdown, a small but growing seaside resort, and during the winter months from dockyard men coming from and going to the docks at noon and at five. Owing to the land in and around Sheerness nearly all belonging to the War Office, no suitable site was found available near the centre of the town, and it was resolved to build the power station and car sheds on some private land near the end of the line, where a supply of water from a well could be got from the owner of the land.

The power station buildings are of local yellow stocks, the chimney stack being of steel plates on a brick base. The design of the station was kept on the standard lines of the other stations of allied companies at Weston-super-Mare, Birkdale, Banbury, etc. The boiler-room, which is 39ft. in width, contains three Babcock-Wilcox boilers, two of which are in a battery, with a heating surface of 3,200 square feet each. The condenser, together with other apparatus, as feed pumps, feed heater, hot-well, grease separator, etc., has been put up in a separate room, and was supplied by Messrs. Allen and Sons, Bedford, and fitted with Edward's air-pumps. The feed pumps are made by Messrs. Weir and Co., and the grease separator by Holden and Brooke. In order to be quite safe from oil entering the water-tube boilers, a Rankine filter was also installed. The steam-piping, supplied by Messrs. Babcock and Wilcox, consists of one main header interconnecting the branches to the boilers and engines in such a way that each boiler supplies its own engine in a straight line. The engine-room is 32ft. 6in. wide and well lighted and ventilated. The engines are three high-speed Browett and Lindley enclosed type, coupled to three Brush 100-kw. continuous-current dynamos generating at from 420 to 550 volts. The generators are of the four-pole type for 450 revolutions, and have light aluminium brush-holders. They are provided with equalising switches mounted on the same base as the series field breaking switches, to enable the generators to run in parallel on the traction load. The switchboard is of black slate and of the usual B.T.H. pattern, with generator panels on the one side and feeder panels on the other. There are, further, a balancer-booster set and a storage battery for the lighting load, of ample capacity, while the roof of the battery-room is constructed strong enough to carry a traction battery later on, should this be desirable. The engine-room is spanned by a 10-ton overhead traveller. The feed and circulating water is supplied, as mentioned before, from a well some few hundred yards away by an air-driven plant on the well known American system.

Digitized by Google

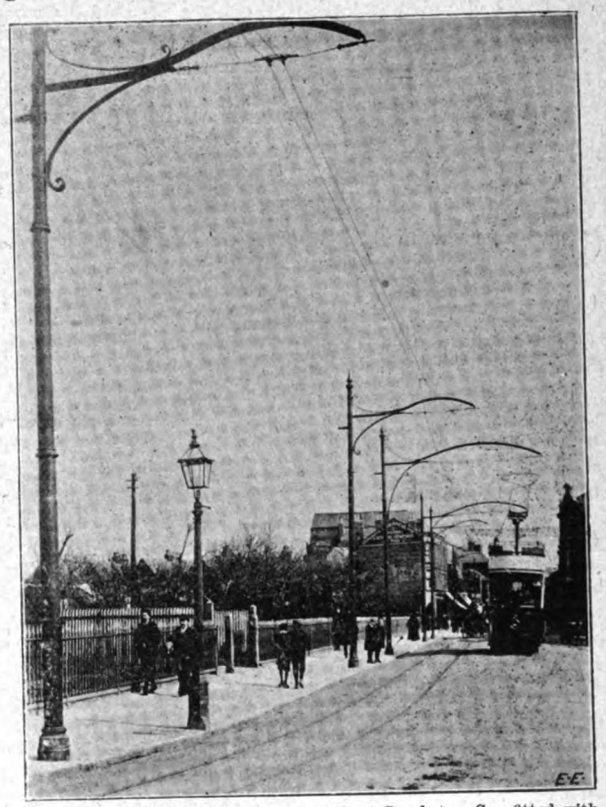
The 12 cars at present constituting the rolling-stock are all double-deckers, each carrying 26 outside and 22 inside, and were built, together with the electrical equipments, by the Brush Electrical Engineering Company at their Falcon Works. The brakes adopted are hand and electrical brakes, and the lifeguards are on the Tidswell pattern of a somewhat lighter construction. The cars are fitted with a sliding bow instead of the usual trolley, and this sliding bow together with the overhead equipment constitutes a decided novelty, as it is the first installation of this kind in England. The light and gracefully shaped bow is carried on a steel base which also carries the spring. In a later pattern, however, this spring is mounted inside the base like an ordinary trolley base.



Car Sheds, Sheerness.

Side Pole Construction, Sheerness.

The car-sheds have been built by Messrs. Johnes to the design of the architect, Mr. W. Gray, and are of galvanised iron on a concrete base. They have room for 18 cars on five tracks, two of which are built over pits 6ft. deep. Provision is made for effecting ordinary repairs, a shop for that purpose being fitted with lathes and drilling plant, etc. The sheds and shops are well lighted and ventilated. The shunting yard is conspicuous for the absence of switches and frogs in the overhead gear, and compares very favourably with a shunting yard for a trolley line. The tracks are laid on wooden sleepers and are well ballasted. The total length of the track is 2½ miles—2¼ miles of which is single and a quarter mile double track. The gauge is 3ft. 6in., on account of the narrow streets in Sheerness. The track is laid on a bed of concrete under the rails only, in order to keep down capital costs, and was constructed by Messrs. J. G. White and Co. The rails are 91lb. per yard and are in 42ft. lengths. The width of the groove is 1⅛in., although 1¼in. should have been permitted with regard to the traffic, which only consists of broad-tyred



Side Pole Construction with Long and Short Brackets. Car fitted with Sliding Bow in background.

Digitized by Google

carts. The joints are made on the Anchor joint pattern, and double bonded. Cross-bonds occur every 40 yards, and all frogs and crossings have not less than two bonds. The points and crossings, supplied by Messrs. Askham Bros., are of crucible cast steel, with long tongues. The paving consists of granite setts at the turn-outs, and Constable's tar macadam on the single line, with a row of setts along the rails.

The whole of the overhead equipment has been carried out by Messrs. J. G. White and Co., side poles with long and short brackets being used, together with a little span-wire work at some points of the system. The poles are 30ft. long, and planted 6ft. in the earth surrounded by concrete. Mechanical ears are used, while the sliding bow requires special material of an exceedingly pleasing and practical design. It is much lighter and the points of support are less than with a trolley. The same applies to the number of poles used; also there are no frogs and crossings in the overhead equipment. The wire, with a section of 00 B. & S. gauge, is suspended on the bowstring principle, and divided into half-mile sections. Overhead guard and telephone wires, supported on insulators and brackets, are provided, the guard wires being bonded to the track. The cables have been supplied and laid by Callender's Cable and Construction Company on the solid system under the footway. One of the feeders is spliced at the feeder box somewhere near the Crescent, and feeds the half-mile sections on the Parade and West-street. There is only one return feeder, while at the end of the line, near the power station, the track is connected to the negative 'bus bars.

There are at present 1,700 8-c.p. lamps connected to the lighting mains, together with some motors. A feeder to Queenborough has been decided upon, and additional demand for power purposes may be expected from a factory building near the power station.

The entire undertaking has been designed by Mr. Gerald Hooghwinkel, M I.E.E., of the staff of the Electrical Power Distribution Company, Limited, while the buildings and car-sheds were erected to the design of Mr. W. Gray, of 11, Adam-street, London, W.C.

AN ENGINEERING DEGREE, AND HOW TO GET ONE.

BY A.M.

About two years ago the University of London issued regulations for a B.Sc. degree in engineering, and the scheme is now in full working order. How many men now at work in the engineering profession regret that they have no convincing evidence of their knowledge of engineering science. Some, perhaps, possess their college certificate, and find it quite unknown and unrecognised outside of a small district. Others, again, have passed the associateship examination of the Institution of Civil Engineers. But what of the young electrical engineer who aspires to higher posts, whose chief is not perhaps a member, and able to nominate him for membership of the Institution of Civil Engineers? To him and to many others the new degree offers the advantage of a hallmark of the very highest class, and yet one which may by hard work be won in the leisure time of the engineer engaged in his profession. Some of the provincial universities have granted their degrees in engineering for years past, but these have generally only been open to those fortunate enough to be able to take a fairly complete day course of instruction, the qualification being by attendance and examination; and many well-trained men from other institutions are left with no widely recognised diploma.

The older science degrees of London University are, in academic circles, held in estimation second to none, and the up-to-date syllabus of subjects and the ground covered by them ensures for the new engineering degree a similar high regard among technical engineers—and one which is almost certain to increase with years. The Institution of Civil Engineers accept holders of this degree for associateship without requiring them to pass the usual examination.

How can such a degree be obtained? In the first place, like almost everything else worth having, it means work. If the aspirant is residing in London, he had better consult the head of the engineering department of one of the many institutions comprising or affiliated to the London University. But to take a more general case. Suppose his work lies in the provinces. His first stage will, to an engineer, offer, perhaps, the greatest difficulty of any; he must, if he has not already done so, pass the matriculation examination. But even matriculation is not so dreadful now: Latin, the bugbear of so many students of science, is no longer a compulsory subject. The subjects which an engineer would probably choose are: (1) English; (2) elementary mathematics; (3) French; (4) elementary mechanics; (5) elementary physics, chemistry, or geometrical and mechanical drawing. Some assistance with most of these subjects could, if necessary, be obtained in evening classes in nearly any town in this country.

Having matriculated, the more serious work of the intermediate examination begins. The subjects most likely to be undertaken are: (1) mathematics; (2) mechanics; (3) engineering drawing; (4) electricity and magnetism; (5) heat and optics, or chemistry or geology. This examination is by no means a difficult one: the standard of the various subjects is about the same as that of the advanced stage of the Board of Education examinations; a candidate residing within range of an institution in which South Kensington science evening classes are held in these subjects, would be able to get a great amount of assistance from them.

Lastly, there is the B.Sc. or final examination. This examination is, of course, of a higher standard than the two preceding ones, but as the subjects are all those with which the candidates are presumably best acquainted, and in which they are most interested, it does not necessarily offer the greatest obstacle to the ultimate goal. The range of subjects being a large one, a considerable amount of choice is provided, so that the electrical engineer, the mechanical engineer, and the civil engineer can all find a suitable combination. The subjects are divided into two groups. In Group A three subjects have to be taken out of the following four: (1) theory of machines and machine design; (2) theory of structures and structural design; (3) strength and elasticity of materials; (4) electrical technology. In Group B two subjects for a pass, and three for honours, are necessary, selected from the following seven: (1) hydraulics; (2) surveying; (3) theory of heat engines; (4) design of electrical machinery and apparatus; (5) generation, transmission, and distribution of electrical energy; (6) higher mathematics; (7) advanced theory of machines and structures. It will be sufficient to indicate a choice for an all-round engineer, including, of course, electrical knowledge; the modifications for other branches will be obvious. In Group A the subjects of theory of machines, strength of materials, and electrical technology would be presented, and in Group B electrical design and electrical energy, with probably theory of heat engines, if the candidate aims at honours.

In, say, Manchester, where there is an exceptionally large number of technically educated young engineers, evening classes can be found covering the whole range of these subjects. In other large towns not quite so fortunate in the matter of technical education, a very great deal of assistance could be obtained from existing classes even if the entire ground is not covered, while to the man in the more remote country towns there is open correspondence tuition, and, above all, if he has learned how to *read and learn* for himself, there is the great opportunity of self-education.

Full regulations of the examinations with detailed particulars of the ground covered in each subject may be obtained free on application to the external registrar of London University, as may also those of the matriculation examination.

Lastly, there is one other class of persons to whom this subject is of importance—viz., parents, guardians, and advisers of youths who are destined for the engineering profession. The latter are often limited by circumstances to one or perhaps two years at college; to these a degree is still a possibility, for part of the work can be done at college, and the remainder, by an industrious youth, after leaving. There is one most important piece of advice to be urged if a degree is remotely contemplated: let a youth

Digitized by Google

matriculate before leaving school, for his school learning is generally soon forgotten. Even if the degree work is not afterwards followed up, the matriculation certificate is accepted in lieu of the examination for admission as a student of the Institution of Civil Engineers and various other bodies.

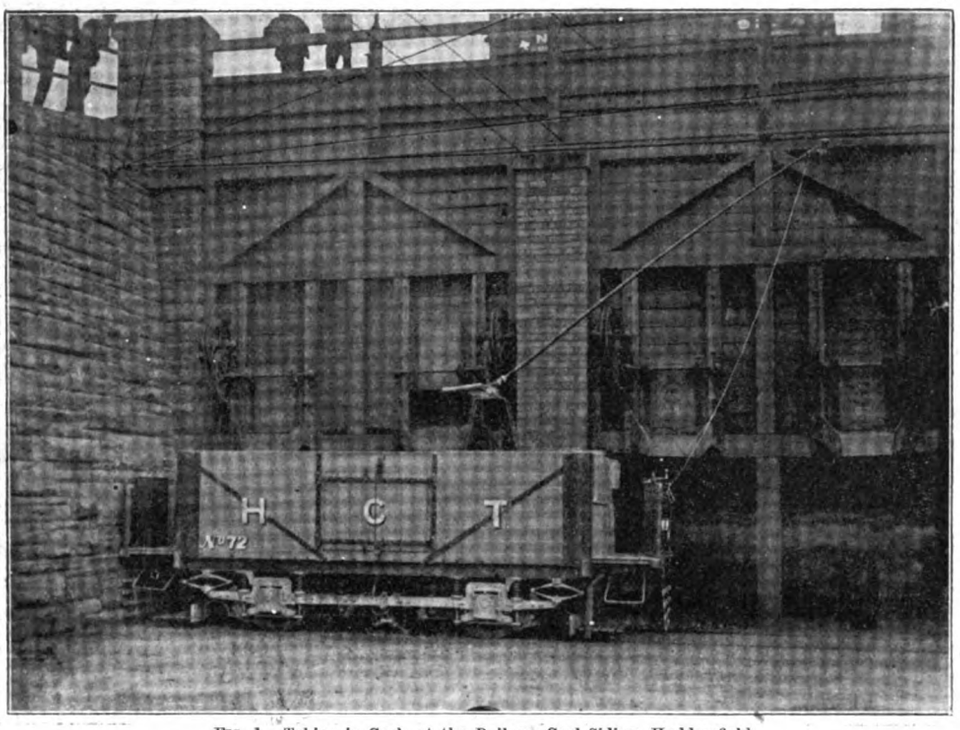


FIG. 1.—Taking in Coals at the Railway Coal Siding, Huddersfield.

ELECTRICAL COAL HAULAGE ON THE HUDDERSFIELD CORPORATION TRAMWAYS.

Through the courtesy of Mr. H. N. Thomas, the general manager and engineer of the tramway department, we are able to give in this week's issue some interesting photographs and particulars of the scheme of electrical coal haulage introduced by him. As our readers will know, Mr. Thomas is leaving the employ of the Huddersfield Corporation to undertake similar duties for the Durban Corporation. In consequence of his early departure for South Africa the trials of this coal delivery wagon have been expedited, and were successfully accomplished last week.

The scheme broadly consists in making the municipal tramways a link between the coal shoots on the railway and the coal bunkers of large manufacturers. In order that this might be done, permission had to be obtained from the railway companies to run a tramway line into their coal yards. The negotiations for this permission were successful, and we must congratulate both Mr. Thomas and his committee on the fact. The difficulty in the way of a settlement was that a tramway authority, which is an active competitor of the railways, was the applicant for the convenience. The Corporation had to approach the joint railway companies—*i.e.*, the London and North-Western and the Lancashire and Yorkshire. As it was a new departure, the matter had to be brought before the directorates of both companies, but it was eventually agreed that the Huddersfield Corporation

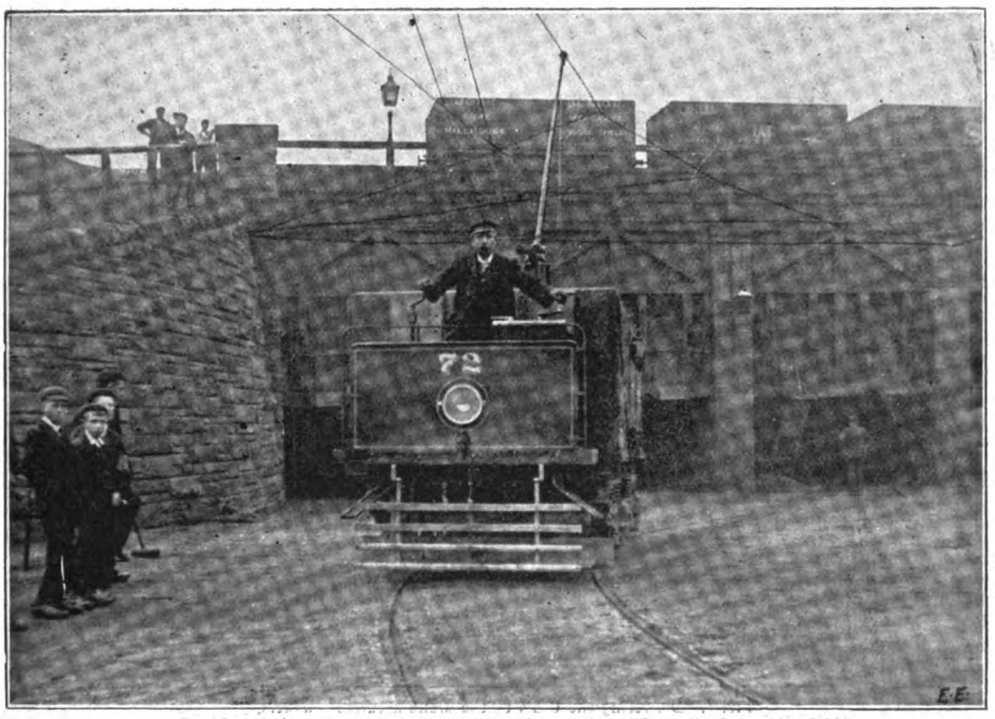

FIG. 2.—The 10-ton Electric Coal Wagon leaving the Railway Yard, Huddersfield.

Digitized by Google

should lay tramlines in the coal-shoots yard at Hillhouse, so that wagons might be run into it and receive the coal from the delivery places at the shoot mouths. The ratification of the agreement was announced at a recent Council meeting. The completion of an agreement between the Corporation and Messrs. Martin, Sons, and Co., Limited, manufacturers, Wellington Mills, Lindley, which had been provisionally on foot for some time, was reported to the same meeting. The Corporation constructed a line running from Bradford-road along Whitestone-lane into the railway coal-shoots yard, a distance of about a quarter of a mile, and Messrs. Martin, Sons, and Co. have constructed a tramway line from the main road, on the way to Salendine Nook, into that portion of the premises where the coal has to be delivered. The overhead equipment for this short line has been put up by the Corporation workmen, under the superintendence of Mr. H. N. Thomas. The total length of the journey from the coal shoots at Hillhouse to the delivery place at Wellington Mills is about four miles.

Our photographs (which were taken by the chief engineering assistant, Mr. J. C. Whiteley) are most interesting, and due credit must be given to this gentleman for the assistance he has rendered to his chief in the carrying out of this pioneering work.

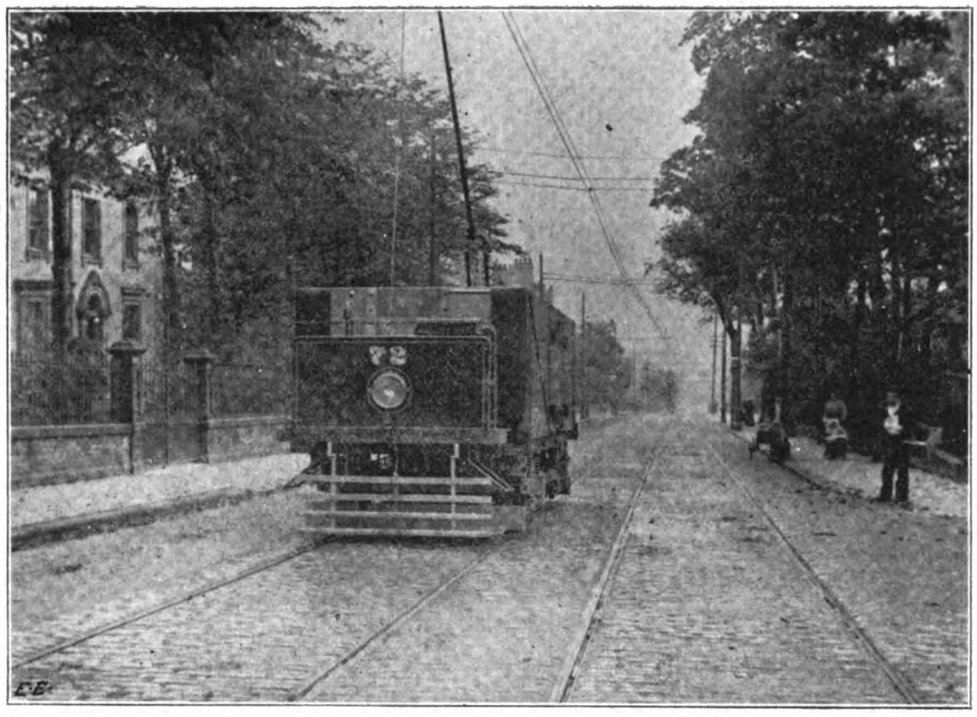

FIG. 3.—Electric Coal Haulage on the Huddersfield Corporation Tramways.

In these photographs Fig. 1 shows the wagon in position at Hillhouse coal sidings, Huddersfield, under the shoots. Fig. 2 is of a loaded coal wagon leaving the coal siding. Fig. 3 shows a coal wagon on the line of route through one of the residential districts; the grade the wagon is standing on is 1 in 18. Fig. 4 is the final stage, where the wagon is discharging coal in the bunkers at Martin's Mill.

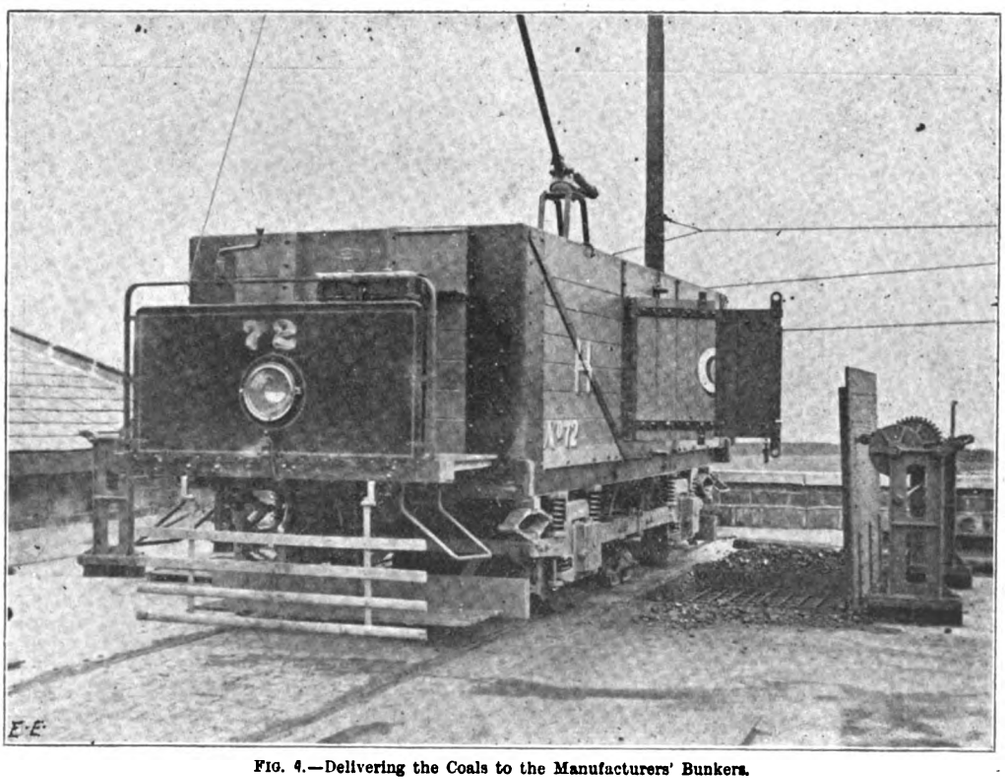

FIG. 4.—Delivering the Coals to the Manufacturers' Bunkers.

It will be seen from this that the wagon is not unlike an ordinary coal wagon. It is designed to hold 10 tons. The wagon is made so that the coal can be discharged from each

Digitized by Google

side simultaneously. The body of the wagon was constructed by Messrs. Milnes, Voss, and Co., of Birkenhead, and it is mounted on a radial truck manufactured by the Brush Electrical Engineering Company. It is equipped with two Westinghouse 80 motors, each of approximately about 45 h.p., and it is also equipped with a Westinghouse-Newall magnetic brake and a powerful hand-brake. It is fitted with a special axle arrangement for enabling the wagons to pass easily round curves, an arrangement which has only been patented recently. The wagon is also supplied with the usual sanding apparatus, and is as complete as it can be for the purpose for which it is intended. The trolley pole has to be longer than those used on the ordinary cars, because of the height of the wagon being so much less. The car can be driven from either end, as is the case with the ordinary cars. The wagon had to be specially designed in order to cope with a difficulty which was at once seen at the coal shoots. The wagon body was too high to admit of coal being taken endways, as is the case with carts, under the delivery shoots. A line parallel with the face of the shoots had to be constructed in the shoots yard, so that the wagon may be taken alongside the delivery shoots, as is shown in the illustrations (Figs. 1 and 2).

Another point resulting from the use of old shoots was that a 3ft. 6in. platform could not be allowed on the wagon, but this had to be reduced to 2ft. 6in. For the same reason the headroom had to be cut down to 7ft. The inauguration ceremony of this new coal service was attended by a large number of interested parties, and we foresee that it will not be long before other manufacturers demand the same convenience from the Corporation. The feature of the case is that the roads in Huddersfield are exceedingly hilly, and the cost of haulage correspondingly great. In consequence, the cost per ton for delivery of coal into outlying works becomes a serious matter, and the introduction of a tramway siding will soon be repaid by the saving in cost. From the Corporation's point of view the service is a good thing, because it can be carried out during the slack periods of the day, or at night, when the tramway lines are not working to their maximum capacity.

We congratulate Mr. Thomas in that he has been able to witness the successful commencement of this service before his departure to Durban, and wish him again every success in his new work.

THE HUMMING OF ELECTRICAL MACHINES.*

Machines of modern design are liable to be more or less noisy, the sound varying from a whistle to a howl, according to circumstances. That it is not merely an air vibration which is in question may be safely admitted, from the fact that the noise usually stops as soon as the excitation is taken off. Also, the same results may be noticed on machines having wide open slots and those having very narrow or half-closed ones. Though this humming is in itself quite harmless, it is very disagreeable when the machine has to work near occupied houses, and cases have occurred in which an otherwise satisfactory machine has had to be replaced due to this cause alone. In stating above that modern machines are liable to this trouble, reference was intended more especially to those having laminated poles, small air-gaps (1·5mm. to 3mm.), and few slots. The difficulty is, in practice, found far less frequently in the older machines having air-gaps of 4mm. to 6mm., solid poles, and numerous slots. It may be mentioned at once that the pitch of the note, as would be expected, depends directly on the number of teeth, whilst the amplitude of the sound falls as the number of teeth increases. Already with 13 to 15 slots per polar arc practically no humming is noticeable, and it disappears entirely with higher numbers. In modern practice much smaller numbers of slots, such as six to nine slots per polar arc, are commonly met with. Experience has, however, shown that with even as low a number of slots per pole as five absolutely silent running is possible under certain conditions, as described below. It happened to be possible, by inserting sheet iron behind the poles, to vary the length of air-gap on certain machines of this sort experimented on, and it was found that, contrary to expectation, this did not appreciably increase the noise.

Whatever the cause of the humming, it is easy to prove that the latter is directly dependent on the number of slots. Of course, the actual seat of the noise is not necessarily the armature itself, but may be in the poles, which are set in vibration by the changes in magnetic field corresponding to the different positions of the armature. By means of the tuning fork the above statements may readily be confirmed. The usual tuning fork of commerce is set for the note la of the fourth octave, and consequently makes 440 vibrations per second. The number of vibrations corresponding to other notes may be seen from the following:

Fourth octave: do = 264 vibrations, re = 297, mi = 330, fa = 352, sol = 396, la = 440, si = 495 vibrations.

Fifth octave: do = 528 vibrations, re = 594, mi = 660, fa = 704, sol = 792, la = 880, si = 990 vibrations.

Sixth octave: do = 792 vibrations, re = 891, and so on.

It is, therefore, only necessary to determine the note by means of the tuning forks, which should offer no difficulty to a fairly musical ear, and at the same time take the speed of the machine. Dividing the number of vibrations corresponding to the note by the number of revolutions per second, the result is the number of vibrations per revolution, which, naturally, must vary directly with the mechanical or magnetic variations to which these vibrations are due.

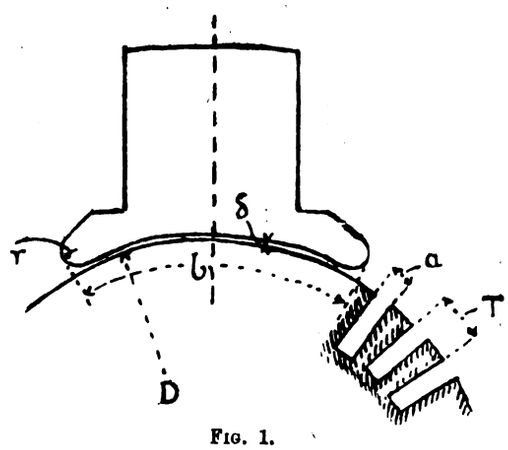

Fig. 1.

A few examples will make the matter clear. An 11-h.p. motor running at 1,070 revolutions per minute, or 17·8 per second, was found to give the note exactly midway between sol and la of the fifth octave, and corresponding to $\frac{792 + 880}{2} = 836$ vibrations per second, so that the vibrations per revolution are $\frac{836}{17·8} = 47$. As the number of slots in this motor was 47, there can be no doubt the initial cause of the humming lies in the armature slots.

The same experiment was made on a 4·5-kw. dynamo running at 1,400 revolutions per minute, or 23·46 per second. In this case the note was determined with great exactness, and was found to be midway between la and si in the fifth octave, and gives $\frac{880 + 990}{2} = 935$ vibrations per second, or $\frac{935}{23·4} = 40$ per second—*i.e.*, exactly as many as the number of armature slots.

The pole shoes of both machines were next reduced somewhat in span, and this almost entirely stopped the humming. When the pole span was still further reduced the humming commenced again. Other machines tested in the same way with various pole widths and different armature slots (see table) confirmed these results—*i.e.*, a distinct ratio of pole span to slot pitch could be found at which the humming was a minimum. The explanation for this is, as already mentioned, that the total flux passing through the pole varies according to the relative position of the armature and the poles, and, within certain limits, according to the ratio of slot pitch to polar span, and this causes the pole shoes to vibrate. In accordance with this

* Translation of an article by J. Fischer-Hinnen in the *Zeitschrift für Elektrotechnik*.

Digitized by Google

view, the amplitude of the vibrations should be a minimum when the pole span is an exact multiple of the slot pitch. As a matter of fact, this rule in no way agrees with the test results, obviously owing to the effect of fringing of the lines at both sides of the pole-piece.

The writer has attempted to establish a rule, and, so far as his experiments go, the best results would seem to be obtained when the polar arc is made such that the slot pitch (reduced to the diameter of the bore) divides into it an exact number of times + ·5. There is, of course, difficulty in deciding what to call the polar arc when the pole tips are rounded, and in such cases the writer employs the extreme outer pole span less ·7 of the radius of the rounded tip. Stated algebraically, the rule for minimum humming is:

$$\frac{b - \cdot 7\, r}{(D + 2\,\delta)\,\pi} \cdot N_1 = \text{a whole number} + \cdot 5,$$

where N_1 is the number of slots, and the meanings of the other letters can be obtained from Fig. 1. The more closely this quotient approaches to a whole number the greater is the danger of humming, except when the number of slots is very great—*i.e.*, over 13 to 15 per pole span.

PARTICULARS OF MACHINES ACTUALLY CONSTRUCTED (see Fig. 1).

No.	Armature diameter, D.	Single air-gap, δ.	No. of slots, N_1.	Slot pitch, T.	Slot width, a.	Polar arc, b.	Radius of rounded tips, r.	K_1.
1	200	1·5	39	17·1	7	120·2	4·7	6·84

21	440	3	117	12	5·5	239·5	9·2	19·4
22	440	3	75	18·7	8	239·5	9·2	12·45
23	370	2	93	12·6	6	205	8·5	15·8
24	400	2·5	86	14·8	7·5	214	9	14
25	400	2	87	14·6	6·8	214	9	14·2

REMARKS.—Nos. 1 to 13, bad humming; Nos. 14 to 25, no humming. Nos. 4, 6, 8, and 18 had slanting poles.

This table shows that the rule given checks fairly well with the experimental results, except in the case of the three last machines, which, however, have a very large number of slots, and this alone may account for their behaviour. In spite of this agreement, however, the writer does not consider the rule to be absolutely reliable, as it takes no account of the slot width. If we consider the slot width reduced indefinitely, we arrive at a smooth-cored armature, which certainly does not hum, and yet the rule would show the contrary. In view of the importance of the matter, the writer hopes that others engaged in dynamo manufacture will test the accuracy of the above rule.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

TELEPHONY AT GLASGOW.

SIR,—"The value of Sheriff Jameson's precious report may be gauged by the contempt with which it has been treated in Glasgow, the city with which it deals, and by the fact that the Government, which appointed him as commissioner, ignored it. With regard to Sheriff Jameson's Glasgow report, it is unfair and misleading to suggest that it questioned the accuracy of my estimate. The sheriff's doubts were understood (by whom?) to refer to the difficulty of repaying capital on the rates proposed, assuming, as he did, that the license would certainly terminate in 1911, and that the Corporation system would not then be bought by the Post Office. Under the new Act the license may be extended to 1925 at the wish of the municipality, and the Post Office will buy the system. My estimate was not so much an estimate as a statement of ascertained cost, since every item was covered by actual tenders from responsible firms, who were prepared to undertake the work at the figures given. The estimate was not shaken, although I was cross-examined on it for the best part of two days by the leading members of the Scottish Bar; and a reference to the Blue-book of the 1898 Select Committee will show that it has been accepted as correct by Mr. Hanbury. It is in effect correct, and as applicable to Dublin as to Glasgow."

These remarks are not my own, but occur in letters signed by A. R. Bennett and published in the *Freeman's Journal* in September, 1899. They show pretty clearly that Mr. Bennett at that time did not read into Sheriff Jameson's report the meaning which he and "W. O. T." now find in it. If "W. O. T." will take the trouble to read the whole paragraph on p. 17 of the report, he will find that the commissioner is speaking throughout of an estimate for a municipal telephone system for Glasgow. If he will refer to p. 4 of the report, he will find that the sheriff refused to enquire into the cost of the National Company's system. Even the part of the commissioner's report which "W. O. T." does quote makes no mention of the suggestion that the estimate was for the purpose of showing what the existing system ought to have cost. It is evident either that this suggestion made no impression upon the mind of the commissioner, or that he considered it a change of front not worthy of attention.

As for "W. O. T.," I am sorry for him. I have patiently borne with his obvious lack of knowledge of the technics of telephony, and with his even more trying impermeability to the meaning of plain English. By close argument and clear marshalling of facts I have driven him out of one ineffective position after another, and he finally takes refuge in a mere verbal quibble. He hoists the white flag, and at the same time tries to give one a furtive stab. I have tried to think better of "W. O. T.," to think that he really wanted the truth, as he has said. Let him read over, in the calm seclusion of his study, his contributions to the last three issues of the *Electrical Engineer*, and if, when he comes to his deplorable quibble on p. 308, he does not blush for himself, then there is no hope for him. Poor "W. O. T."!

I can quite appreciate that one who has such a remarkable record for accuracy and consistency as Mr. Bennett has must become extremely impatient at the stupidity of a poor dull chap like me, who cannot see any reason in describing an estimate for a metallic circuit underground telephone system as an appraisal of the cost of a single-wire overhead system containing fewer exchanges and a considerable smaller length of line. Mr. Bennett apparently argues on these lines: "I have described at various times the same thing in diametrically opposite terms. I choose now to adopt one set of descriptions, and that stupid fellow Webb chooses to adopt the other set. What is the good of Webb quoting one set when I now nail my faith to the other set?"

Mr. Bennett now quotes Colonel Slacke, and gives a partial account of the little tiff at the Hull enquiry, which was the occasion, I believe, of the first appearance since 1897 of the Glasgow estimate as a statement intended to show what the then existing system of the National Telephone Company ought to have cost. However, the whole point of Colonel Slacke's attitude is summed up in the last line which Mr. Bennett quotes, in which the inspector stated that he declined to hear any more of the matter. If Colonel Slacke had been willing to hear the matter out, Mr. Robb would no doubt have made it clear to him, as I think I have made is clear to any unprejudiced person, that it is impossible, in the face of Mr. Bennett's statements in 1898, 1899, and 1900, to accept his present statement that the estimate of 1897 was made for the special purpose of showing what the then existing system in Glasgow ought to have cost the National Telephone Company.

Digitized by Google

In referring to the Hull incident, Mr. Bennett is not more accurate than usual. I made no reference in my evidence at Hull to the original Glasgow estimate. The only reference which occurs in the Hull report to my evidence at Glasgow is on the question of spare plant. There is no warrant for Mr. Bennett's statement that Colonel Slacke committed himself to any strong language as to my conduct. I think the reckless inaccuracy of Mr. Bennett's statements, both as to facts and to people, is a most unfortunate part of this discussion.

As regards Sheriff Jameson's report, to use an expressive phrase from the current slang of the day, Mr. Bennett cannot have it both ways. He has previously referred to the sheriff's report in the polite terms which he customarily applies to anyone who has the misfortune to differ from his views, and it is really hardly decent for him now to quote the report as upholding the entirely opposite view of the matter which he now adopts.

There is a strong resemblance in the history of this telephone estimate to another discussion which has occupied public attention of late. The parallels between Mr. Bennett's Glasgow estimate and the famous "Petersburg" are most striking. At the beginning the estimate is a Volunteer cruiser that knows its business—a man-of-war, bow, stern, and amidships; in other words, a full-fledged working estimate for a Glasgow municipal exchange equipped with all the latest devices. Challenged at the Dardanelles—the cross-examination at the enquiry is the Dardanelles—the fighting flag flutters to the deck and up goes the innocuous merchant bunting. "Merely a comparison; no working estimate about this, Mr. Sultan—that is, Commissioner." But once past the Dardanelles, the Glasgow enquiry over and blue water ahead, the man-of-war flag is broken out again, the ammunition hoists click fluently, and the guns bristle. "Estimate, indeed! No, Sir, no mere estimate; statement of ascertained cost. Fight anybody with this, anywhere. Sink any objections in short order." Poor merchantmen, editors, engineers, commissioners, and other small fry riddled and wrecked in most contemptuous manner. Later on, strong protests are made in light of ascertained facts. Fighting flag comes down with a run and merchant ensign covers the whole ship. "Working estimate? Never. Special commission expired long ago. Never was an estimate, never could be an estimate, nobody ever could take it for an estimate. Object merely to show what something entirely different ought to have cost." Unfortunately, it is not possible to make the instructions for the estimate to turn itself into a statement of what something else ought to have cost reach the right quarters, because between the azure covers of certain official records the estimate sails on serenely through the ages as a detailed working estimate for Glasgow municipal exchange. The parallel is not complete, but it is interesting as far as it goes.—Yours, etc.,

HERBERT LAWS WEBB.

35, Old Queen-street, Westminster, S.W.,
Aug. 29, 1904.

SIR,—Mr. Webb is delightful, but editors are grumpy, and I am told telephony at Glasgow "must not run the paper." Editors are human, but this telephone question *is* important. Mr. Webb is not nice to me; but I have heard somewhere that it is the custom of lawyers when they have no case to slang their opponents. On these grounds, I should say that Mr. Webb is fully conversant with the fact he has no case. Words were given to us to hide our real thoughts; he has enough words—what about his thoughts? Now let us come to grips, if we can, for Mr. Webb is more slippery than an eel, and boxes the compass admirably.

Aug. 5.—**Mr. Webb** leads off with the right, referring to 1897 estimate, which he *assumed* applied to work *to be* carried out. He leads to the inference that cost of installation should be proportionate to instruments or subscribers.

"**W. O. T.**" replies cost is *not* proportionate to instruments or subscribers, and that the estimate referred to was *not* an estimate for any work which Mr. Bennett proposed to carry out.

Aug. 12.—**Mr. Webb** is compelled to agree that "W. O. T." is, at any rate, partially correct, but will bring in other factors besides area as having influence on cost. [Inasmuch as Mr. Webb admitted the non-proportionality of cost with number of subscribers or instruments, my point was carried.] Mr. Webb now brought in a lot of questions, all based upon this assumed estimate.

"**W. O. T.**" replies, quoting Bennett, that this much-abused estimate was *not* for the purpose Mr. Webb *assumed* that it was. [Here we get: Webb says *yes*, Bennett says *no*—a direct negative. Bennett made the estimate, and surely he *must* know what he made it for. Query: which of the two is most likely right. I, as an outsider, say the man who knows, not the man who thinks he knows.]

Aug. 19.—**Mr. Webb** gives copious extracts from the minutes of evidence to support his "Yes." [He italicises some words, which he deems the most important. He is right; but again, to an impartial outsider these words seem to support Bennett's, not Webb's view (*vide* p. 271, column 2): "Not so much an estimate as a statement of ascertained cost." Webb says "'tis an estimate." Bennett says it isn't. Which is right—the man who prepared the statement, or the man who criticised it? Further, what did Bennett mean by "ascertained cost?" Cost of what—something to be done? If so, it was an estimate. Something done; if so, it was what Bennett says it is.]

"**W. O. T.**" merely states his interpretation of the evidence.

Mr. Bennett gives further extracts, showing most conclusively that the estimate or statement was not for what he wanted to do, as is Mr. Webb's contention, but for purposes of comparison. He also refers to Mr. Salveson's interpretation corroborative of his case.

Aug. 26.—**Mr. Webb** wobbles—he pretends he wants to settle a point, but judiciously goes to something else. He won't have Mr. Bennett's view, supported as it is by the evidence in chief, in re-examination, and in Mr. Salveson's interpretation, and he introduces the question of *metallic* circuits as a proof that Bennett, Salveson, and myself don't know what we are talking about. I cannot speak for two of these gentlemen, but Q. 5,040, 5,041, 5,043, 5,359 certainly bear out their views and my views, and in my opinion are quite consistent with the questions quoted by Webb. Then Mr. Webb goes on to be great on words. Mr. Bennett's reply (5,359) contained these words: "For the specific purpose of ascertaining the approximate cost of such a system as exists here." Webb's fencing with words is simply to draw a red herring over the scent, but it is too thin, Mr. Webb—too thin.

Mr. Bennett gives extracts corroborative of his view which came out at the Hull enquiry.

"**W. O. T.**" further corroborates Bennett by a quotation from the judge or commissioner's report, which is to all outsiders abolutely conclusive.

To-day we get another stage. I must not accept Jameson's view of a particular point because Bennett has ridiculed the report, and the Government did not act on it. Really, Mr. Webb, can you put that forward as aiding you. The point is *estimate*, not report. I do not know why Bennett or Glasgow or the Government put aside the report. I only know it corroborated the view that Bennett put forward about this estimate. The evidence that I can get from all the sources indicated serves the same purpose, and corroborates Bennett. Mr. Webb need not be sorry for me—let him first think of himself. I have read Jameson's report (p. 17), and what Mr. Webb says of the paragraph is distinctly wrong. The commissioner is *not* speaking of Bennett, as Webb would have me and others infer, and in this, and so far as I know, his writings for the first time, Webb descends to the use of contemptible weapons. The commissioner speaks of an estimate obtained from an unknown expert by Mr. Starke. There he says what I gave in the quotation (Aug. 26) about Bennett, then he goes on to Glasgow's indebtedness.—W. O. T.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notices of Meetings, Issues of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had by Order from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	— 6s. 6d.	— 13s. 0d.
Other Places	5s. 6d.	— 10s. 6d.	— 21s. 0d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

GLASGOW TRAMWAY ACCOUNTS.

The accounts of the Glasgow Corporation tramways department for the year ended May 31, 1904, are, of course, of supreme interest to the inhabitants of Glasgow. The information given in the publication is most complete, and is also of general interest, because it shows to other local authorities exactly what the Glasgow Corporation is doing. Without contradiction, we may say that the tramway department in this important Scotch town is a credit to the country, and that those responsible for the policy, financial and otherwise, are energetic and cautious business men. We are not surprised, however, to find that our contemporary, *Electrical Investments*, feels called upon to step in and warn the Glasgow people of their financial deficiencies, and of the consequent difficulties ahead. This publication—which one is led to suppose is intended for the "investor, director, councillor, engineer, manufacturer, contractor, etc."—is obviously shocked at the financial ruin hanging over the Glasgow tramway department. It manfully steps into the breach, and, to quote its own words complains of many things. For instance, our contemporary says:

"Many persons, of course, are satisfied with the general appearance of things, and do not trouble to look beneath the surface; and to all such it may appear that if the Glasgow tramways are well organised and efficiently operated, all is well, and nothing more need be said. But it must be remembered that this is a public undertaking on a very large scale, and involving very heavy capital expenditure; it is, further, the principal municipal tramway system in the kingdom, and is frequently cited as a conclusive argument in favour of municipalisation of the tramways in other communities; and for these reasons it is necessary to do more than enquire into the ability and efficiency of the staff. We must consider the financial policy of the Corporation or its responsible committee, and see whether the community has really benefited by municipalisation."

Our contemporary then gives the comparison between the revenue accounts for 1903 and 1904. It goes on to say: "It will be seen that the traffic receipts have increased in the year by £64,693. 6s., a very substantial and meritorious increase, indicating at once the popularity of the cars and the increasing demand for this means of locomotion; but what has it cost the Corporation to earn this increase in revenue? For a financial undertaking that is the important point. The working expenses for the year 1902-03 were £431,870. 2s. 11d., while those for 1903-04 are £496,266. 14s. 11d., an increase of £64,396. 12s. Thus the whole of the increase in traffic receipts has been swallowed up in working expenses, and if it were not for the increase in the item 'Other receipts,' the undertaking would have shown this year a balance to net revenue account almost identical with that for the previous year. Now, is this satisfactory? We do not think any company would find it so, nor would the town councillors of Glasgow if they were shareholders in a company showing these returns. The traffic revenue per car mile has decreased from 11·19d. to 10·58d.—that is, by 0·61d.—and the working expenses per car mile have increased from 5·21d. to 5·26d. The committee explains this increase as being 'altogether due to the increase in the amount of taxes and accident insurance,' while the decrease in revenue is 'chiefly due to the augmented service of cars which is now given on all routes.' But can either of these statements be accepted as satisfactory?"

Lastly, it attacks the Corporation for having devoted £62,000 out of the net revenue to special depreciation of various portions of their plant. It asks, "What is special depreciation?" and accuses the department of creating the

Digitized by Google

term in order that a sum which is ordinary depreciation should swell the net revenue. Our contemporary concludes: "The revenue per car mile is declining year by year, and difficulties would appear to be ahead. The present policy tends to concealment of the true position, and may lead to great abuse when the difficulties arrive. Let the Council take warning in time."

We must say we are amused by the criticisms, which have not an atom of sense in them from beginning to end. It is hardly worth while troubling our readers with a few words exposing the special pleading in the article. As, however, the printing of mis-statements is supposed to render these unimpeachable, it may be well to mention one or two points. In the first place, it is quite true that the increase in traffic returns for the year has been equalised by a practically similar increase in the expenses. In other words, a more frequent service has been given at an increased cost, but the increased revenue has justified the improvement in the transport facilities. We presume that the advocates of company management will always fail to understand the argument which Mr. Garcke was the first to lay down—*i.e.*, that municipal undertakings should not make a profit. We then come to the question of the decrease in the revenue per car mile, which the Tramway Committee attribute to the augmented service of cars. We fail to see how any further reason is possible, in view of the fact that the total revenue is increased. Perhaps our contemporary thinks that with too many cars on the route people refuse to travel at all for fear they should get on to the wrong car. Lastly, we come to the depreciation question, which is the stock argument of the British Electric Traction Company and their numerous experts against corporation management. It is true that these arguments must not be applied to British Electric Traction undertakings, as otherwise their position would not bear investigation. After reminding our contemporary of the old proverb that "a rose with any other name would smell as sweet," we propose to contrast the Glasgow figures with one of the oldest companies under the British Electric Traction Company's *régime*. Thus, at Glasgow the capital account at the beginning of the last financial year stood at £2,129,512. As a result of the year's work the following large sums were applied to depreciation, or the repayment of capital, between which we see no difference. The items are: sinking fund, £45,552; depreciation, £78,619; special depreciation, £62,000. These amounts have a total of £186,171, or 8¾ per cent. on the capital above mentioned. Of course, the capital account has been added to during the year, but some £43,000 was also distributed between the "common good" and the reserve fund. These figures may show faults in the present policy and difficulties ahead, but the faults can only be in points of book-keeping and the difficulties in the minds of interested parties. We now turn to the accounts of the Potteries Electric Traction Company, and one would expect from the fact that Mr. Emile Garcke—the leading authority on depreciation—is a member of the Board, that this company would give Glasgow points on the depreciation question. The company for 1902 had an issued share capital of £490,000, and £220,000 of debenture stock. For that year, the last for which we have figures, the company had a net revenue, after paying debenture interest, of £23,299, or about 4¾ per cent. on its issued capital. Obviously, this should all have been put to depreciation, but the company voted the magnificent sum of £2,000 to depreciation—*i.e.*, 0·41 per cent.—and divided the rest as dividends. In our opinion the difficulties mentioned above are not far ahead in this case. These are the facts, but we are quite sure that our contemporary will ignore them, and that the argument of the insufficient depreciation of municipal undertakings will still be harped upon by the directors of the company above mentioned.

REVIEWS.

The Telephone Service: Its Past, Its Present, and Its Future. By HERBERT LAWS WEBB, M.I.E.E. Illustrated. Whittaker and Co. Price 1s.

Mr. Webb is an able, facile, and forcible writer; but in this book the writing is too much that of an advocate. It is largely controversial, not educational. He is always concerned for his verdict. The information he gives is interesting, but the grip of the advocate causes lapses in the narrative—which lapses in a court of law would be filled in by the opposing counsel. Thus in the brief historical chapter we read of Bell, Edison, and Hunning, but never a word of Hughes—a greater than either Edison or Hunning. Edison was a telephonic inventor by accident. He really had noticed—to the disadvantage of the experiments upon which he was engaged—the effects of loose contacts. Hughes, too, discovered these effects and worked out the discovery to practical purpose. Hunning merely constructed a good useful variant of the microphone. To class him with Bell, Hughes, and Edison is a mistake. He is not in the same hemisphere, much less upon the same pedestal. We merely ask that Hughes—one of the kindest, ablest, and most modest of men—should receive the recognition that is his due. As Mr. Webb says, we have had "20 years of continuous invention to produce a method fulfilling all requirements in a simple, reliable, and rapid manner." We agree, but would prefer to restrict the meaning of invention to such discoveries as those of Bell, Hughes, and Edison. All the rest has been comparatively simple—the mere adaptation of things well known to effect a desired object. Invention has not ceased, nor has adaptation of known inventions, so, although we have attained to an effective simple system, there is no doubt improvements will still continue.

Mr. Webb condemns the early telephone user as asking for and expecting too much, and grumbling because he did not get it (p. 14). Ought he not rather to put most of this blame upon the proper shoulders? The users did not know the capabilities of the then system. They asked solely for what was promised by promoters, exploiters, and speculators, who promised all and every, but did not keep their promises. Blame these men for much—we had nearly said all of the trouble telephonic. Mr. Webb himself, in his ardent desire to pose as an advocate, sails too close to the promise of the ideal in his remarks on the celerity of communication. The ideal state is vastly different from the real, as may be gathered from a comparison of the remarks (pp. 26 and 34). On the former page the author idealises; on the latter, and also on p. 43, he refers to the actual. We may repeat that throughout this little book whenever the author is not touching upon questions of policy—that is, whenever he is not *the* advocate, but is describing systems and apparatus—he is excellent both in matter and manner. Upon questions of policy the advocate is paramount, and, we are bound to say, inconclusive. Most of our remarks must be devoted to policy, but that must not be permitted to hide the high opinion formed as to capability to treat clearly and correctly the technical questions. Thus the functions of a telephone exchange (p. 30), the apparatus and organisation used to satisfy these functions (pp. 30-53), are admirably described. Even when advocacy is the controlling factor the case is clearly and temperately put, only it is not the whole case—only that part tending to prove the premeditated conclusions. In other words, these conclusions are not derived naturally from the premises, but the premises are constructed to fit the conclusions required. A prominent part of the controversial portion of the book deals with the question of tariffs, and this is the only part where the author is not clear. He touches the question on pp. 27, 28, 47, 48, 55, devotes Chapter VIII. to it—and in this chapter p. 93 is most important, concluding with a

Digitized by Google

suggestion in regard to it in his construction policy (p. 115). The usage of "message rate," "message mile rate," throughout the book is misleading. What is meant is not a message rate, nor a message mile rate, but a combination rate—a combination of a flat and a message rate somewhat on the lines of the Wright system of charging as used in electric lighting. A message rate is a misnomer; there is no such thing, there can be no such thing. It is unthinkable and absolutely unpractical. A combination rate is practical, and perhaps the best system hitherto devised, but there is something to be said against that part of the combination rate which takes into account messages. Mr. Webb is infatuated with the message rate; it is his ideal, and in the eagerness of the advocate he overlooks some points. Let us try to summarise our view of the case, premising that a summary is not a full and detailed account. Assume that Mr. Webb is invited to estimate for and prepare a telephone system for a town—any town. He cannot deal first with messages or message miles, which shows that messages occupy a secondary, not a fundamental place. He is bound in the first place—and he cannot depart one iota from such a course—to obtain an idea of number of subscribers—that is, of lines. Nothing comes before this. He objects to estimates founded upon lines, but in this he is wrong. The position of subscribers gives him the area, also density factor. The classification of subscribers gives him message rates and times of demand, for each class of subscriber has its own message rates and time of maximum demand. These are known from statistics obtained from practical working, and neither genius nor ability will enable an expert to fortell them. Thus he gradually builds up sufficient information to enable him to design and estimate. You can no more determine message rates or message mile rates *ab initio* than you can fly; the message rate is statistical, and not predetermined. Pioneers in telephony had no statistics to guide them; they were in the dark, they knew not how many messages an attendant could handle; they had to meet subscribers who said, "How much?" and would not listen about a flexible rate, so that a flat rate was in those days almost the only one possible. It was soon seen, however, that telephony was a little out of the ordinary run of businesses, and approximated to that of electric lighting. Two branches of expenditure—roughly speaking—had to be satisfied out of revenue, that involved in construction—call this constructional—and that involved in the daily working. The demand of constructional cost upon revenue can be fairly easily determined, and this should form a flat rate in the combination rate which ultimately forms the tariff.

Mr. Webb, as we say, is strong upon a message rate, or a message mile rate. The latter is not worth consideration, and the former is "not correct in theory" (p. 94), as can easily be shown. Working costs are not proportionate to number of messages, but to message groups, or, better still, to message time-groups. An attendant can handle a given number—call this a group—of messages in a given time, hence the suggestion, time-groups. The time-group may—the figures are purely abstract—as a maximum be placed at 20 per minute. No group, then, between one per minute and 20 per minute affects attendants' wages, which form one portion of working costs. Similarly, there will be a time-group for junction lines, and so on. Thus between certain limits working costs are not affected, and these limits are in no case individual messages. Hence a message rate is not idealistic, nor "correct in theory"; it may be held by Mr. Webb to be intensely practical—which is another thing. But even then the rate would form but one part of the combination tariff, which consists, as we say, of a demand upon revenue to satisfy constructional and working expenses. We take it that Mr. Webb really means this combination rate for his tariffs as described on p. 93. But we must pass on.

Unfortunately, telephonic writers have got into the habit—and we know use is second nature—of seeing something abnormal in every telephonic detail, where, as a matter of fact, no such abnormal condition exists. There is nothing unique, though Mr. Webb claims it (p. 62) when he says, "One great difficulty with telephone traffic is that it comes in such uneven volumes at different times of the day, etc." . . . or "causes the service to be much more expensive to conduct" (p. 63), or "plant . . . staff must be organised to deal with the traffic without delay at the busiest hour of the day" (p. 63); or "at night the whole plant is practically idle" (pp. 64-5). These conditions hold in half the businesses carried on in this world, and are understood as part of the disabilities to be encountered. Why telephonists should arrogate to themselves something uncommon in these conditions would be laughable if they were not so evidently in earnest. Surely constant iteration has made them believe, but a moment's thought would show the futility of such claims. Every shop has its busy and slack times, its plant idle, etc., its night as well as its day. Nor can we admit the claim of unique, Chapter VI., pp. 66-75: "In every telephone connection there are two subscribers concerned, and unless the two perform their respective shares of the transaction satisfactorily, the general result will not be satisfactory." The statement is true, but not unique. It is used to emphasise the correct suggestion that the supplier of apparatus and system should hand to his subscribers the most simple, the most perfect apparatus. Let that subscriber do as little thinking as possible, and do as little work as possible in order to ensure satisfaction all round. The same moral can be applied to almost every business transaction, be it the posting of a letter, the sending of a telegram, or the buying of a piece of cheese.

The last three chapters are solely devoted to advocacy. The statements are *ex parte*, almost all controvertible and untenable. There is only one, however, which we shall trouble to deal with. It is like to the character of the previously mentioned unique and abnormal—that is, a statement so often made as to be taken for true without examination, yet, when examined, it contains hardly a shred of truth. Here it is: "The principal of these (things tending to restrict the systematic development of British telephony) is that the telephone companies have never had powers to run wires" (p. 104). We say, and say it deliberately, that the statement made in the sentence quoted is absolutely untrue from the first to the last word. It is the pretensions of the companies that are unique and abnormal. Why should they, purely money-making concerns, ask for powers to be given them which other individuals do not possess—nay, ask for them as something which is their right, and which powers are to be practically gratuitous? They ask for rights in and over public streets and private property—powers that shall minimise their capital and increase their revenue-earning capacity. They (private adventurers) get all the benefit to the detriment of the general public. Surely they can, if they choose, buy land or buy rights to use land, and so run their wires over or under the ground as they like. It is not they cannot buy land and run wire. They won't; they want something for nothing, and a more selfish, grasping, one-sided, sordid policy was never before promulgated. Because a careless Legislature has permitted gas, electric light, water, and other companies to use the public streets for private benefit, a right for everybody to do so is not constituted. Let the telephone companies buy the land or the right to use the land they require, neither individual, nor the public, nor the Legislature will say them nay. Of course, someone will say, But how about crossing the streets? Does any sane individual believe that this would constitute a real difficulty either with council or Legislature? The difficulty arises because the companies ask, not what is just, but too much. The most effective argument against companies is given to the municipalities because of this outrageous claim. We have a good deal of criticism and comparison of Government and commercial working. The Post Office is not a commercial undertaking, never was, and never will be. It is run by the State, not for profit-making, but something very different, better, and nobler.

It is clear that Mr. Webb does not quite understand the telegraphic accounts of the Post Office—nor for the matter of that does one man in a million. Were these accounts presented in commercial fashion they would startle many a talented but ill-informed writer, but at any rate we should not get such statements as "the loss on the telephone and telegraph business will before long wipe out the present handsome profit on the postal and money order

Digitized by Google

business." Will Mr. Webb kindly tell us the capital value of the telegraphs of this country, and how that value appears in the accounts he so casually condemns? Before talking of losses he will find he has a good deal to consider when he really commences to investigate. We shall never agree with Mr. Webb while he retains this style of the pure advocate, yet we should probably agree with many of his conclusions with regard to municipal and Government businesses, though from different premises Mr. Webb is a gentleman destined in the future to take a foremost position if he will broaden his views and consider both sides of the question, with the object of ascertaining what is best and right, and not with a view of proving a particular or preconceived case. Let us have more of the judge, less of the advocate. He possesses qualities of the highest calibre. His method of stating his case is excellent. Even when his materials will not bear strict examination, he makes the best of them. With his technical descriptions we have no fault to find—here he is evidently quite at home; it is his politics that are faulty, yet his work is well worth consideration, for he puts his case in the simplest way, and is evidently in earnest. The only lapses—and for an advocate these are of the mildest—are p. 105, where he speaks of "much unjust and superficial criticism," and in his preface, when he speaks of "these discussions are usually marred by a lack of knowledge on the part of many participants" "We are not all infallible, not even the youngest of us," said a politician; hence the honest man admits ignorance and desires enlightenment. May we all get it according to our needs! How exceedingly difficult it is to review a book of this kind may be seen from two quotations. *First*: "It is sad to contemplate the manner in which the electrical industries in this country have been strangled by over-legislation and State interference." This we deny. *Second*: "The State monopoly has stamped out invention and manufacturing enterprise in telegraph work in Britain." With this we agree, but to give the reasons for denial or agreement would be wearisome.

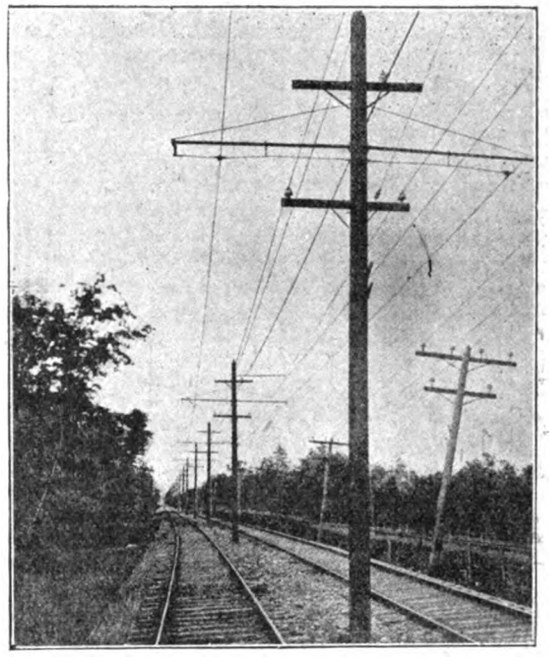
THE SINGLE-PHASE COMPENSATED MOTOR

The General Electric Company, of Schenectady, N.Y., has just developed a new single-phase motor of the compensated type, of which an interesting description is given in the *Electrical Review* of New York. A trial was made on the 19th ult. over the Ballston section of the Schenectady Railway Company, a distance of about 16 miles. This line has been operated with the standard direct-current apparatus, and for the purpose of testing the new alternating-current motor a second trolley wire was erected over each track, from which the alternating current is taken. We reproduce a view of this line, showing both direct and alternating current trolley lines The compensated motors and control are adapted for operation on the 2,000-volt alternating-current trolley between cities and the standard 600-volt direct-current trolley in Schenectady. This ability of the compensated motor equipments to run over tracks equipped with either alternating-current or direct-current trolley makes their field of application very broad, as the cars can secure all the benefit of running over existing city tracks without in any way sacrificing their running qualities upon suburban sections equipped with alternating-current trolley.

Centre-pole bracket construction is used, there being two brackets supporting the two 600-volt direct-current trolley wires and a cross-arm supporting the two 2,200-volt alternating-current trolley wires. The Ballston extension has been operated for several months with direct-current equipments, and their operation being continued in part necessitated an additional set of trolley wires for the alternating-current equipments which would not interfere with the direct-current trolleys. The centre poles are 34ft. long, and are spaced 100ft. apart, the alternating-current and direct-current trolley wires being No. 000 grooved section, with no feeders for the alternating-current trolley, and with a 500,000 circular mils feeder reinforcing the direct-current trolley. The direct-current trolley conforms to standard bracket construction, and presents no unusual features, while the alternating-current trolley wire is suspended from a $\frac{3}{8}$in. steel catenary. The alternating-current trolley is clipped to the catenary midway between poles, and the catenary in turn is hung over porcelain insulators on wooden cross-arms, the whole forming a construction of great flexibility, with the further advantage of providing excellent insulation with standard porcelain insulators and eliminating the span wires adjacent to the trolley wire, thereby preventing the pole catching should the trolley wheel leave the wire.

With the alternating-current system using a trolley and track return there is an inductive drop in the trolley and rails with an additional loss in the latter case due to eddy currents and hysteresis. Measurements made upon the Ballston line indicate an apparent trolley resistance of 1·3 times the ohmic resistance, and a rail resistance 6 55 times the ohmic resistance.

The resistance of the alternating-current trolley wire is somewhat reduced by the steel catenary in parallel with it. The alternating-current trolley wires are 5ft. apart and 16·5ft. above track, while the four 75lb. track rails are tied together every 1,500ft. The increased resistance with alternating current is a serious factor in low-voltage alternating-current city systems, but since the compensated motor operates perfectly with the direct current of city systems, no general necessity exists for a low-voltage alternating-current trolley.



When it is desired to make use of or instal a three-phase generator to take care of the operation of rotary converters, induction motors, etc, the preferred arrangement to balance the load at each sub-station is to instal three-phase, two-phase transformers connected two-phase on the secondary side and feeding separate trolley sections from the two phases.

The compensated motor consists of an annular laminated iron field with a distributed winding similar to that of an induction motor, and an armature provided with a commutator similar in general mechanical construction to a direct-current railway motor armature. These motors are wound for 200 volts, are permanently connected two in series, and are fed from the 400-volt secondary of an 80-kw. air-blast step-down transformer carried on the car. The distributed character of the field winding compensates for the armature reaction, so that power factors are relatively high throughout the range of operation. This type of motor is so designed that at the free-running speed of the car, which is the condition most frequently met with in suburban work, the power factor and efficiency are nearly at their maximum values.

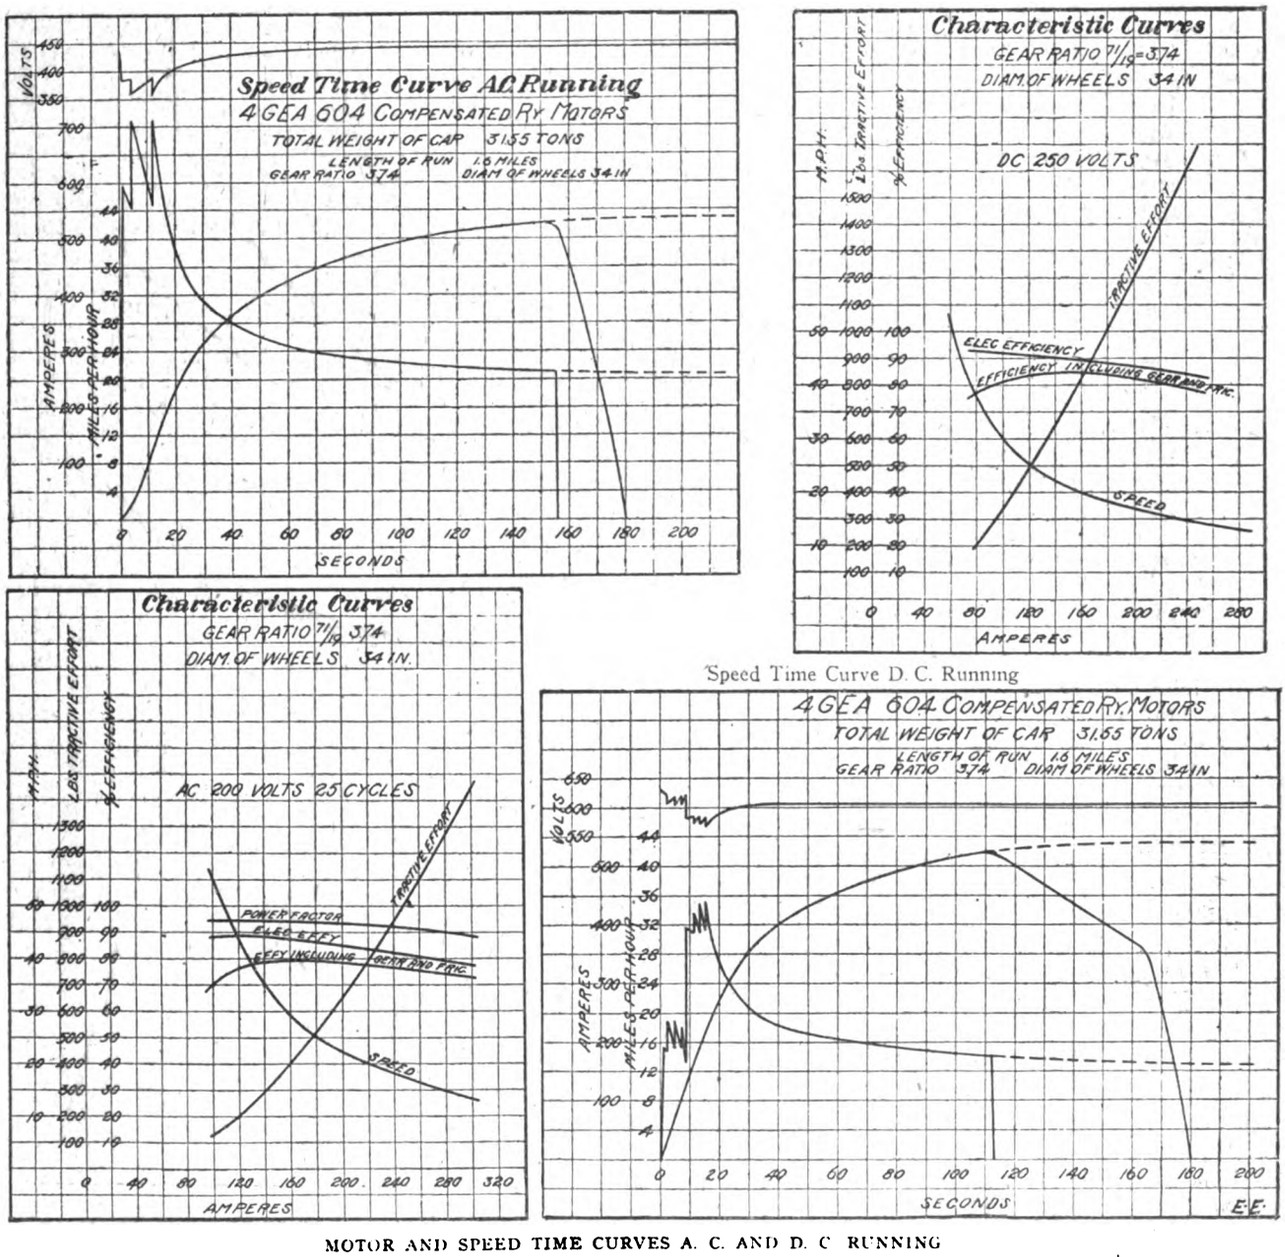
A set of motor characteristics is shown in the accompanying diagrams for both alternating-current and direct-current running. It will be noted that the speed torque charac-

Digitized by Google

teristics for alternating-current running are equal to direct-current running in meeting the requirements of railway work. Unlike the multiphase induction motor with its practically constant-speed characteristic, the compensated motor varies its speed with the load, and is thus better adapted to operate trains over an irregular profile. The commutation of the compensated motor is equally satisfactory when running alternating current or direct current, and this good commutation is secured by careful electrical and mechanical design without using high-resistance leads.

There is a comparatively small additional expense required to adapt alternating-current equipment to run either alternating current or direct current, and in the case of the Ballston line this is accomplished with the use of a standard K 28, direct-current, series-parallel controller used in connection with a commutating switch to change field connections, cut-out step-down transformer, change line fuses, etc. The time required to operate the commutating switch is but a few seconds.

It is instructive to compare the performance of the compensated motor equipment when operated with alternating current and direct current. The accompanying speed-time curves were taken over the same stretch of track with alternating current and repeated with direct current. The direct-current speed-time and ampere-time curves are typical, and require no particular comment. The alternating-current run, taken under exactly similar conditions, over the same track, illustrates what can be expected from series-parallel control with compensated motors. The rate of acceleration is somewhat lower in the alternating-current run, hence requiring the application of power up to the moment of braking. The shape of the speed-time curve also is characteristic of alternating-current motor work—that is, a comparatively short time on the controller with a large amount of motor curve acceleration. The short period of fractional voltage running of alternating-current motors makes the method of their control of secondary importance,



Speed Time Curve D. C. Running

MOTOR AND SPEED TIME CURVES A. C. AND D. C RUNNING

The following constants apply to both sets of runs:

COMPARATIVE ALTERNATING-CURRENT AND DIRECT-CURRENT RUNS.

	Direct current.	Alternating current.
Length of runs	1·6 miles	1·6 miles
Weight of car	31·55 tons	31·55 tons
Time	180 seconds	180 seconds
Average current power on	229 amperes	346 amperes
Average voltage	606	425
Volt-amperes full speed on level	98	110
Volt-ampere hours per ton-mile of given run	86·3	125·5
Average speed	32 m.p.h.	32 m.p.h.
Schedule speed, including 15 seconds' stop	29·5	29·5

The low volt-ampere hours per ton-mile of the direct-current run is partly due to the better efficiency and power factor of the compensated motor when run direct current, and partly due to the somewhat higher rate of acceleration, permitting some coasting and resulting in a more efficient speed-time curve. The difference in volt-amperes alternating current and direct current depends upon the length of a given run, and the values approach each other more nearly with a run of greater length. It will be noted that the compensated motors run the car at practically the and largely minimises the economy of potential control over series-parallel control.

Digitized by Google

same speed with 200 volts per motor, alternating current, and 300 volts, direct current. This uniform speed is obtained by series-parallelling the fields.

SOUTHWARK ELECTRICITY ACCOUNTS.

The following are abstracts of the revenue account and balance-sheet of the Southwark electricity department, together with statement of electricity generated, sold, etc., for the year ended March 31, 1904.

REVENUE ACCOUNT.

Dr. Expenditure.	£	s.	d.
Generation of electricity	4,907	18	9
Distribution of electricity	303	6	7
Public lamps	536	18	5
Rents, rates, and taxes	628	5	5
Management	826	18	3
Special charges	76	0	0
Balance carried to net revenue account	4,951	17	2
	£12,231	4	8

Cr. Income.	£	s.	d.
Sale of current	11,982	2	1
Rental of meters	151	4	3
Sale of lamps	57	1	3
Repairs to apparatus, etc.	10	17	11
Supervision on private works	29	19	2
	£12,231	4	8

BALANCE-SHEET.

Dr. Liabilities.	£	s.	d.
Loans outstanding	78,555	0	0
Sundry creditors	982	16	10
Cash due to borough treasurer, etc.	7,235	10	5
Net revenue account—amount at credit of	224	6	1
	£86,997	13	4

Cr. Assets.	£	s.	d.
Property, permanent works, etc.	81,899	8	11
Stock of cable, coal, etc., in hand	387	7	1
Sundry debtors and insurance	4,710	17	4
	£86,997	13	4

STATEMENT OF ELECTRICITY GENERATED, SOLD, ETC.

Quantity generated in B.T.U.		833,208
Quantity sold { Public lamps	254,586	793,418
Quantity sold { Private consumers	538,832	
Quantity used on works		29,810

PERSONAL.

The Darlington Council have increased the salary of the borough electrical engineer, Mr. Lunn, by £100, making it £350 per annum.

On Tuesday night Mr. Thomas, the retiring manager of Huddersfield tramways, was presented at the athletic rooms of the tramways department with a breakfast tureen and a silver cigar case. The presentation was made on behalf of the employés by Mr. Whiteley, chief assistant engineer. Mr. Hartley (traffic assistant) occupied the chair. Mr. Thomas shortly proceeds to Durban to take up his new duties there, and from the congratulatory addresses by Messrs. Whiteley, Hollingworth, Booth, and Stringer it was evident that Mr. Thomas takes the heartiest good wishes of his former staff with him.

The Ilkeston Tramways Committee have appointed Mr. A. C. Gilbert as permanent manager of the tramways at a salary of £175 per annum.

Mr. William Drysdale, A.M.I.E.E., chief assistant engineer, Corporation electricity works, Falkirk, has been appointed chief assistant electrical engineer for the borough of Weymouth and Melcombe Regis at a commencing salary of £120. There were 130 applicants. Mr. Drysdale has been about two years in his Falkirk position.

Mr. Kirton, manager of the Lancaster Corporation tramways, has been appointed manager of the new Keighley tramways. The salary of the post is £104 per annum, and there were 140 applicants.

The salary of Mr. Samuel Gordon, cashier of the Aberdeen tramway department, has been increased from £200 to £225.

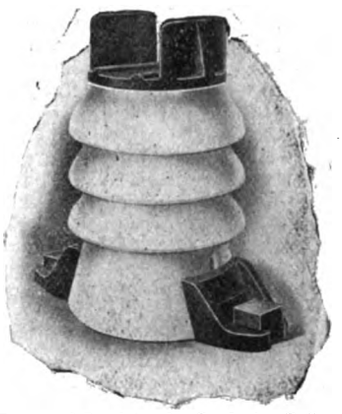
Mr. Andrew Nance, manager of the Belfast Street Tramways Company, has been appointed general manager of the Belfast Corporation tramways. We understand that the salary is to date from Jan. 1, 1905, at £1,250 for the first year, rising by annual increments of £50 to a maximum of £1,500 a year.

On Friday evening a well attended gathering took place at the Mother Red Cap, High-street, Camden Town, the occasion being the presentation of a massive oak spirit cabinet to Mr. William Anderson Brown, the distributing engineer of the electrical department of St. Pancras, on his marriage. The chair was taken by Mr. S. W. Baynes, the chief electrician, and the vice-chair by Mr. Bruce.

TRADE NOTICES AND NOVELTIES.

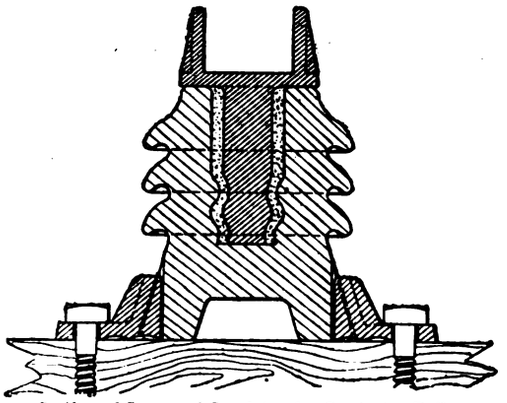
An Improved Insulator for Conductor Rails.

Among the many problems attending the substitution of electric power for steam locomotives in railway working, of no small importance is the attainment of a thoroughly satisfactory means of supporting and insulating the conductor rails. It is essential that the rail supports, while providing permanent insulation under the difficult conditions prevailing on railway tracks, should be substantial enough to withstand rough usage and sufficiently strong mechanically to resist considerable vibration and shock. With a view to meeting these requirements,



Improved Insulator for Conductor Rails.

Messrs. Doulton and Co., Limited, of Lambeth, London, who have had considerable experience in the manufacture of insulators of this class, have patented a new rail support. It consists of a pedestal of porcelain of substantial proportions, with a large base resting direct upon the rail-tie and secured thereto by external malleable iron fastenings. In this respect it differs considerably from earlier types of rail insulators, in which the



Section of Improved Insulator for Conductor Rails.

porcelain is supported on a central stud after the manner of telegraph insulators. The conductor rail is held in position by a chair of malleable iron, provided with a depending stud which is cemented into a recess in the insulator. The insulator shown in the accompanying illustrations is fitted with a chair for a conductor rail of rectangular section. The same type is supplied with chairs adapted for other sections of rail—*e.g.*, flanged or channel sections. The insulator is of high-grade vitreous porcelain of a form well adapted for manufacture, and it will be seen from the illustrations that it occupies the whole of the vertical space below the rail, thus presenting a maximum length of path to resist surface leakage of current.

Ediswan Catalogues.

We have received from the Edison and Swan United Electric Light Company, Limited, three new catalogue sections—namely: Section I., "Royal Ediswan" lamps; Section IV., measuring instruments; and Section V., wires and cables. Section I. contains all the latest forms of "Ediswan" lamps, and embraces low and high voltage standard lamps, high candle-power lamps, "Queen" reflector lamps, obscured, tubular, crinkled, and olive lamps, "Royal Ediswan" traction and ship lamps, and a large variety of special small-bulb patterns, as well as focus, cell-viewing, and radiator lamps. A good deal of useful information is also set forth at the commencement. Section IV. deals with measuring instruments of all sorts. A large number of pages are devoted to the "Ediswan" gravity and moving-coil instruments, and these are listed in a large number of sizes and varieties in order to meet all requirements. Tables of dimensions and diagrams for mounting are also provided. Amongst moving-coil instruments we notice the "Sector"

Digitized by Google

and "Edgewise" patterns. The former can be provided either to mount direct on the switchboard or on brackets when required to revolve, or for fixing at end of slate. The "Edgewise" pattern is provided with the usual bracket for moving in a vertical plane, but can also be fitted on the top of the switchboard. Special attention is drawn to the "Ediswan" separate shunts for ammeters, which are claimed to be the best of their kind, being made without any soldered joints, and thus avoiding all thermo-electric and contact E.M.F. effects. Milliampere and millivolt meters also find a place; these are built on the moving-coil principle. Cardew voltmeters—which we understand were originally made by the company—are listed in many varieties; and there is a large selection of "Ediswan" cell testing instruments for small readings, and portable instruments for large readings, lamp testing ammeters, detectors, galvanometers, etc. The remainder of the catalogue is devoted to a selection of recording instruments, meters, and testing sets. Section V. is devoted entirely to wires and cables (which are listed in large variety), in vulcanised and pure rubber, lead covered, armoured, concentric, and many other patterns. Flexible cords receive special attention, including flexibles for dynamos and switchboards, motorcars, ships, bells, telephones, etc.; and some very useful pages are added for fuse, binding, and resistance wires. The introduction comprises some useful information on joint-making, a table for calculating fall of potential, and a wiring table for "Royal Ediswan" lamps, showing how many lamps of various candle-power, voltages, and wattages can be fed by different standard cables, both on the basis of 1,000 amperes per square inch and on the basis of the I.E.E. rules.

APPOINTMENTS VACANT.

Demonstrator in Engineering, London County Council Paddington technical institute, Saltram-crescent, W. Salary, £150 per annum. Applications by Sept. 14. See advertisement in last issue.

Shift Engineer, Ipswich Corporation electric supply and tramways departments. Salary, £90 per annum. See advertisement in last issue.

Electrical Engineer with central-station experience. Capital required, about £5,000. See advertisement.

Electrical Engineer to take charge of the driving and lighting plant of printing works. See advertisement.

Sub-station Attendants. See advertisement.

Junior Assistant, to take charge of light shift and assist during evening on switchboard. Wages, 25s. per week. See advertisement.

Electrical Fires in the States.—The electrical bureau of the National Board of Fire Underwriters of the United States has issued its quarterly report on electrical fires, from which we extract the following points in regard to causes. Twenty crosses of telephone, telegraph, and other signalling circuits with lighting and power circuits have been reported. Twelve fires have been caused by dynamos and motors, in eight cases due to burning out of armature or field coils. Twenty-seven cases of the grounding of circuits are reported, of which 12 were on awnings and metal work of buildings. Five fires have been caused by short-circuit in flexible cord, due principally to the use of defective "commercial" cord with thin rubber insulation, and to the wrapping of the cord around pipes, nails, etc., which injure the insulation. Six fires are reported due to short-circuit of wires in fixtures. Four fires were occasioned by short-circuit in wattmeters, one of the devices being an old-style chemical meter. Four fires were due to the use of open-link fuses, principally in the defective porcelain cut-out blocks. Five fires were caused by the heat from incandescent lamps located near inflammable material. Twelve reports of damage by lightning have been received. In at least four of these fires the lightning entered the building over the lighting or signal wires, which were not protected with reliable protective devices. Six fires have occurred in electric cars. Reports of 145 electrical fires, losses aggregating over £34,400, have been received during the last quarter. Reports have been received of 107 fires, losses aggregating some £2,800,000, supposed to have been due to electricity, but they are not included in this report, as the causes could not be definitely proven as electrical, principally because the fires destroyed the conclusive evidences of their origins. One of these fires occasioned a loss estimated at about £2,400,000. Twenty-nine fires, losses aggregating over £50,000, reported as due to electricity, have, upon further and more reliable investigation, been found to have been due to other causes.

DESCRIPTION OF REFUSE DESTRUCTOR AND ELECTRICAL POWER GENERATING STATION IN COURSE OF ERECTION AT SALTLEY.*

BY D. J. ROBERTS.

This combined scheme has for its object the cremation of all kinds of ordinary house and shop refuse, and the utilisation of the otherwise waste heat from the refuse furnaces for the purpose of raising steam for generating electricity for traction and lighting purposes.

Owing to the rapid growth of our large towns, the question of sites for buildings of this class has become an important item. Few designers are now sufficiently fortunate to have to deal with what they would term an ideal site; however, the author is of opinion that the site of these buildings, especially for a destructor, may be truly termed ideal, with a canal forming one boundary and two approach roads communicating with two of the other boundaries. It is also conveniently situated within the collecting area. In connection with the destructor, it is intended to use one of the above roads as an entrance and the other as an exit to and from the inclined roadway. Owing to the scheme being a joint one, it was necessary to arrange the buildings on the site in such a manner that the destructor house, chimney, and everything in connection with the furnaces should be erected on land belonging to the Corporation of Birmingham (which had an area of about two acres) and the boiler-house and electric power station on land belonging to the Drainage Board. The inclined roadway is arranged to commence adjoining the south-west boundary of the site, and will run in a north-easterly direction and join up to the destructor house in the centre of the front of this building facing the roadway.

Next to the destructor house comes the boiler-house and then the electric power station, all adjoining one to the other. The entrance to the inclined roadway will be from the Drainage Board's private approach road, and adjoining this will be a weigh office, measuring 14ft. by 12ft., with a weighbridge having a table 12ft. by 8ft. and capable of weighing up to 10 tons. In plan the inclined roadway resembles the letter T, this form of plan being due to the site not being of sufficient length to introduce a straight roadway with a sufficiently easy gradient. The cross portion at the lower end will be 150ft. long and 32ft. wide between the parapet walls, and will form an entrance at the one end and an exit at the other to and from the tipping floor. There will be one track only on this portion, which will be 28ft. wide, laid on hard dry filling, supported by retaining walls, and inclined at a gradient of 1 in 18. The remaining portion of the roadway up to the tipping floor will be carried on semicircular arches, 14ft. span, each consisting of three half-brick rings in cement, the haunches being filled in with lime concrete. The total length of this will be 242ft. and 20ft. 2in. wide between the parapet walls and the gradient 1 in 19. There will be two tracks on this section, each 6ft. 4in. wide between the kerb; this width of track will be sufficient to allow of motor vehicles being used should the Health Committee at some future time decide to adopt the use of this form of vehicle.

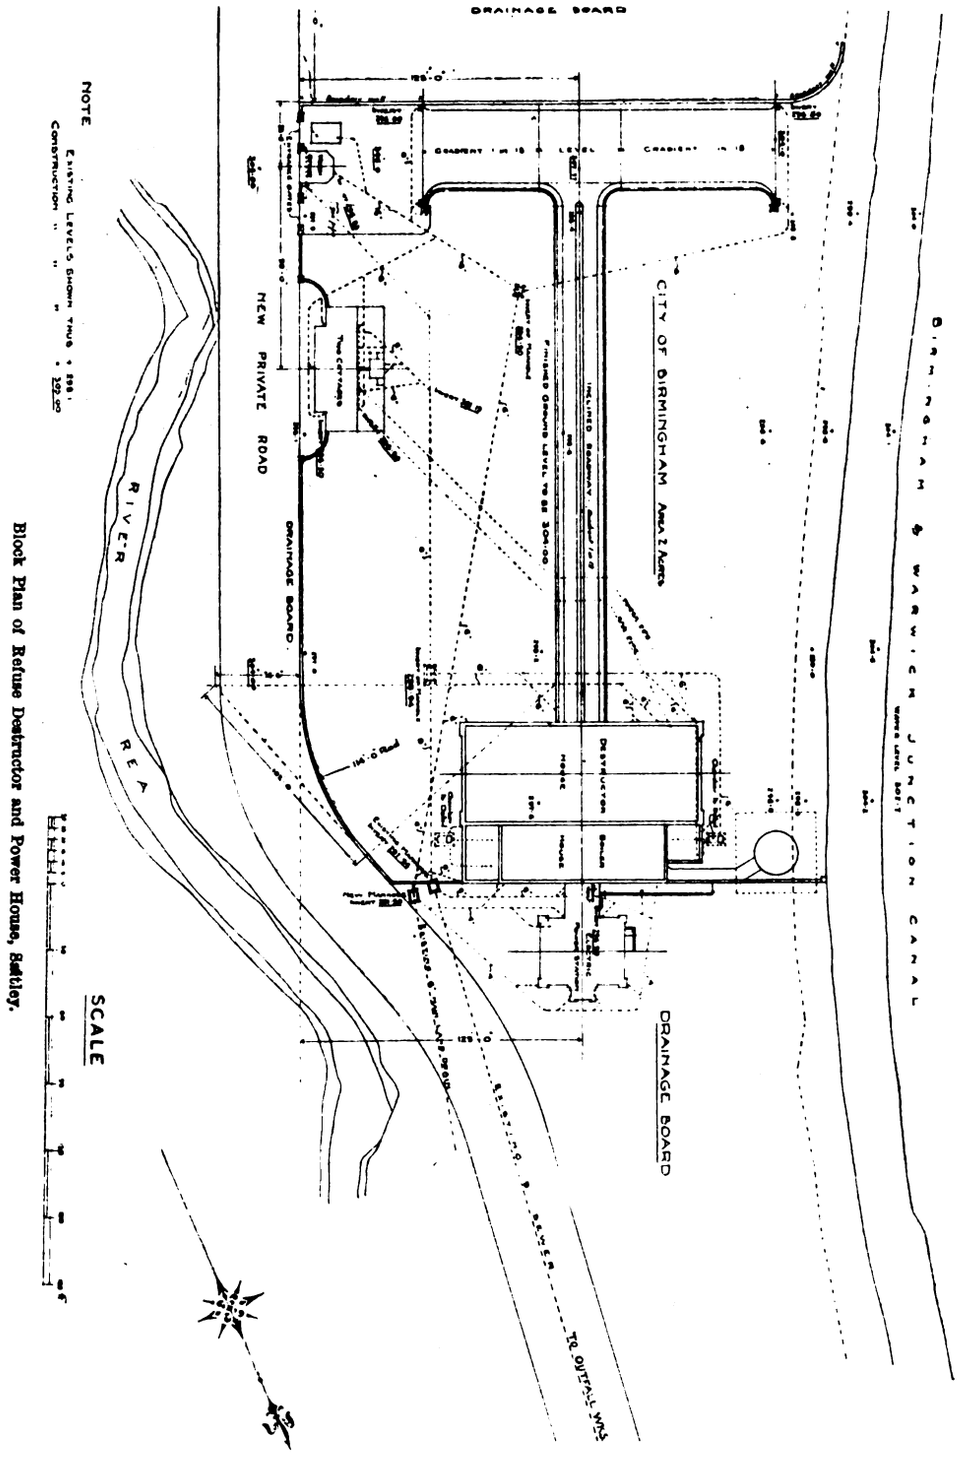
Leaving the inclined roadway, we come to the destructor house. This building will be two storeys in height, measuring internally 104ft. long and 43ft. wide. The ground floor will be divided longitudinally into three sections, of practically equal dimensions, the height from floor to ceiling being 15ft. The first section on the right of the inclined roadway will contain a side entrance passage to the clinkering area, a workshop, storeroom, and a staircase from the clinkering floor up to the tipping floor. The workshop and storeroom will be heated by means of steam on the low-pressure system, the heating pipes being 3in. diameter cast-iron pipes suspended from the ceilings. At the one end of the line of piping will be a steam-trap to run off condensation, and at the other end next the main steam-pipe will be a 1in. reducing valve to reduce the pressure from 160lb. to 10lb. per square inch, and also a stop-valve for the purpose of shutting off the system when

* Abstract of paper read before the Association of Municipal and County Engineers.

Digitized by Google

not required. Immediately opposite the inclined roadway will be a pump-room, in which will be placed at present two boiler feed pumps and one hydraulic pump for working the rams of the feed doors to the cells, and space will be reserved for a small electric lighting set, which is intended to be put in at a later date. The size of this room will be 20ft. 2in. by 18ft. 6in. Owing to this room being immediately opposite the inclined roadway, the difficulty of securing light has been overcome by placing the end abutment to the arches of the inclined roadway about 6ft. from the front of the building, to allow of two large windows being fixed one on either side of the room under the roadway. The two boiler feed pumps will be "Mumford's" vertical pumps, with 6in. diameter steam-cylinders and 4in. diameter water-cylinders with 6in stroke, each capable of delivering 2,400 gallons per hour against a pressure of 160lb. per square inch. The hydraulic pump will be "Heenan's three-throw," capable of maintaining a pressure of 10cwt. to the square inch, directly coupled to an entirely enclosed steam-engine of about 12 b.h.p.

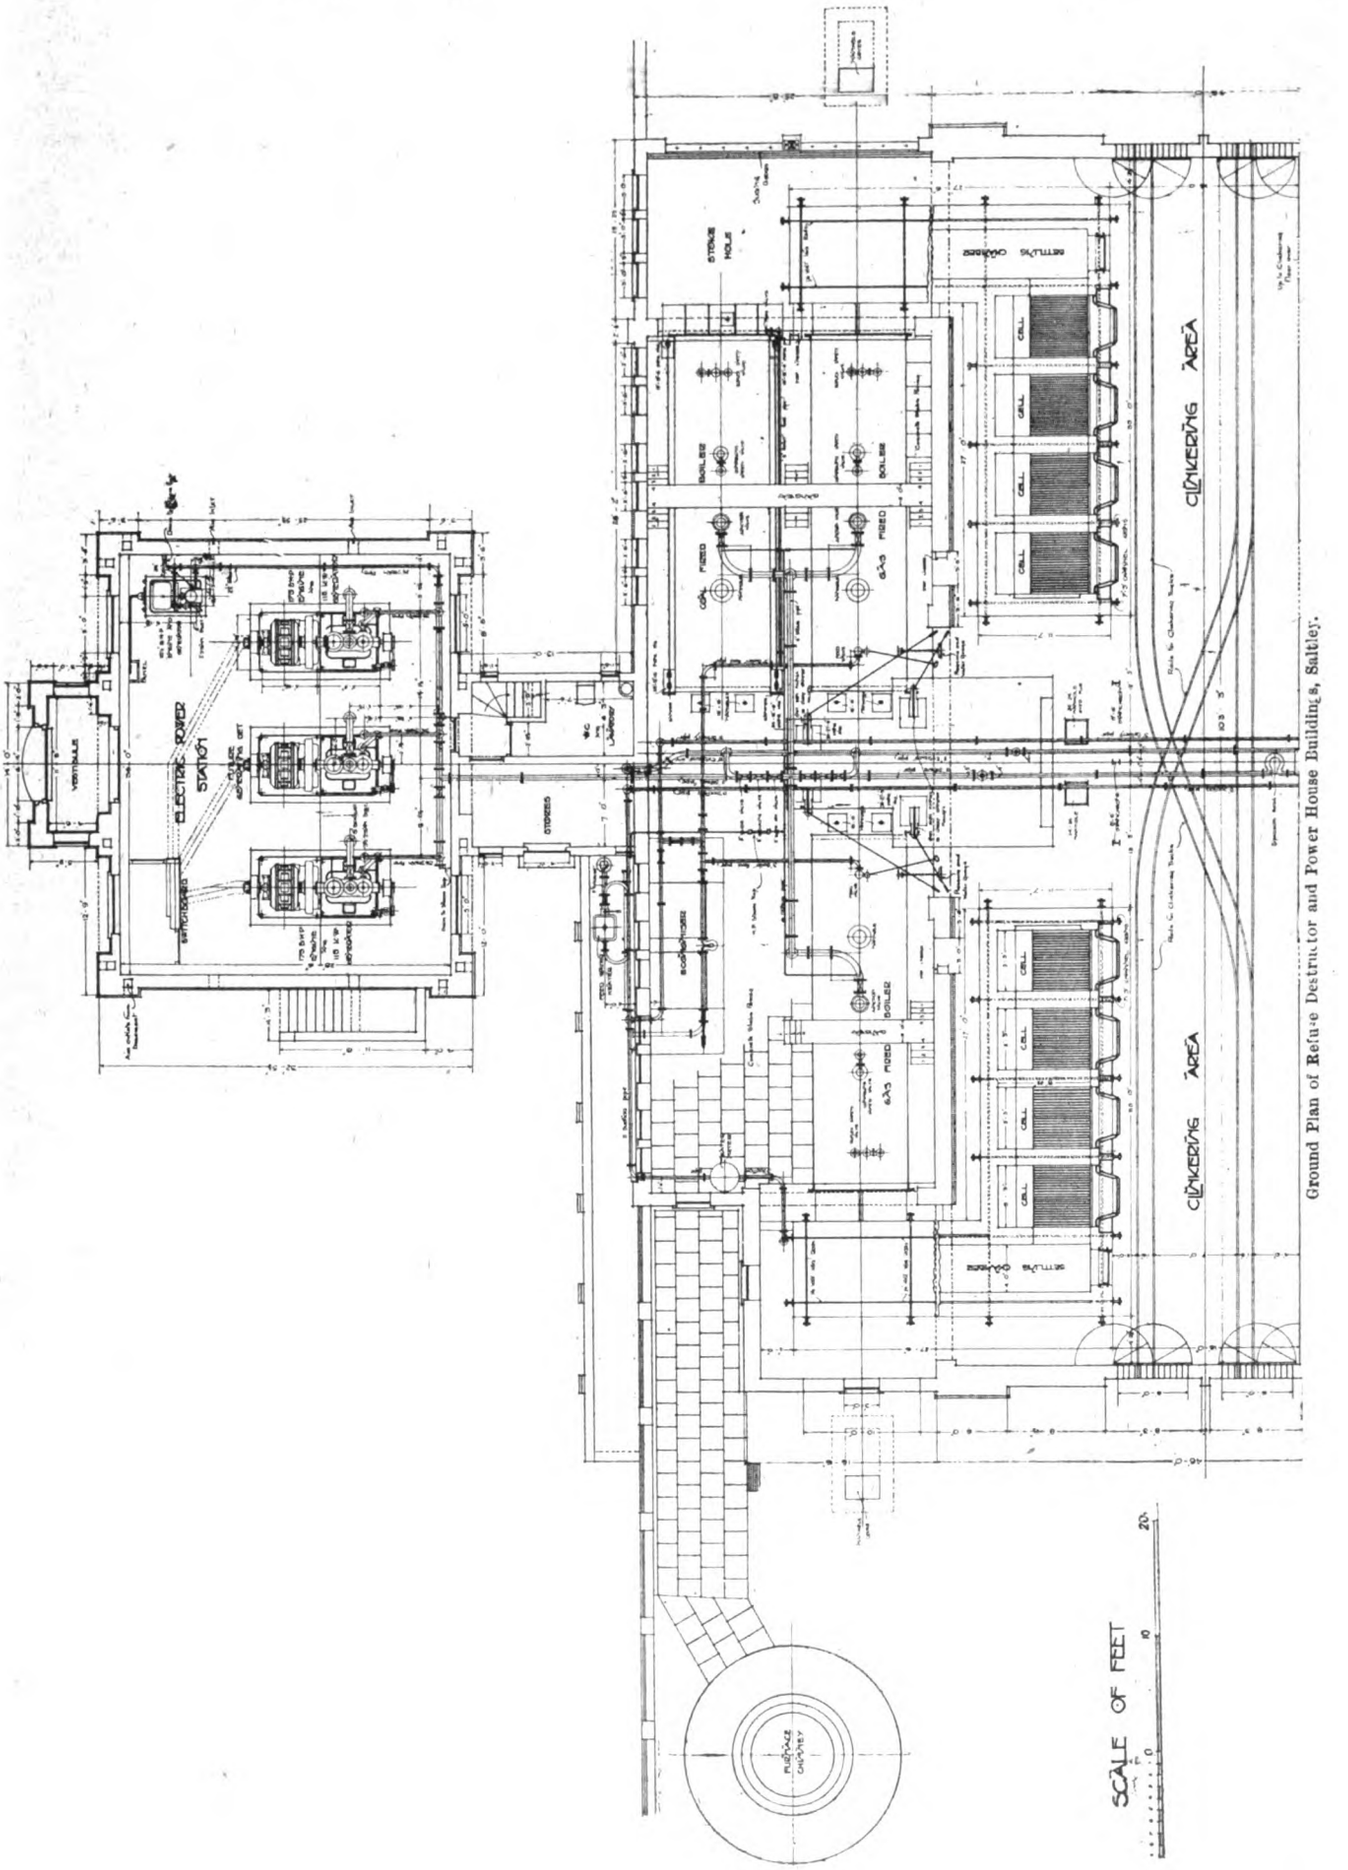
The cells to be erected are those known as the "Heenan patent top feed," the makers being Messrs. Heenan and Froude, Manchester. Each cell will have a grate area of 25 square feet. There will be eight of these cells arranged in two distinct sets, each set consisting of four cells, one air heater and fan, and one settling chamber 24ft. by 4ft. by 10ft, connected to one boiler and forming one unit of plant. The cells and settling chambers internally will be entirely lined with 9in. of fire brickwork, and externally with common hard brickwork 14in. thick, and between this outer and inner lining of brickwork there will be a 1½in. cavity filled up with wired silicate of cotton. The whole of the brickwork to the cells and the settling chamber will be braced together by means of 6in. by 2½in. double channels placed vertically at intervals of about 6ft. 9in. These will in turn be secured to horizontal 10in. by 3in. channels let in flush with the brickwork, and fixed in such a position as to take the thrust of the arched covers of the cells. The vertical double channels will be of sufficient length to extend about 9in. above the brick-work for the purpose of receiving the ends of the 1½in.



Block Plan of Refuse Destructor and Power House, Saltley.

Digitized by Google

diameter tierods, which are to bind together one side with the other. The fronts of the cells will be of very heavy construction, each weighing something like 45cwt. Each front will be fitted with regulating valves to adjust the admission of heated air from the heaters both above and below the grates. The hot air will be conveyed from the heaters to the cells below floor, in brick ducts 30in. wide and 24in. deep, running under the entire length of each set of cells, immediately under the fire-grates. The clinkering doors will be lined internally with firebrick, and arranged to slide upwards and balance by means of balance weights. Such portions of the fronts to the cells that are not covered



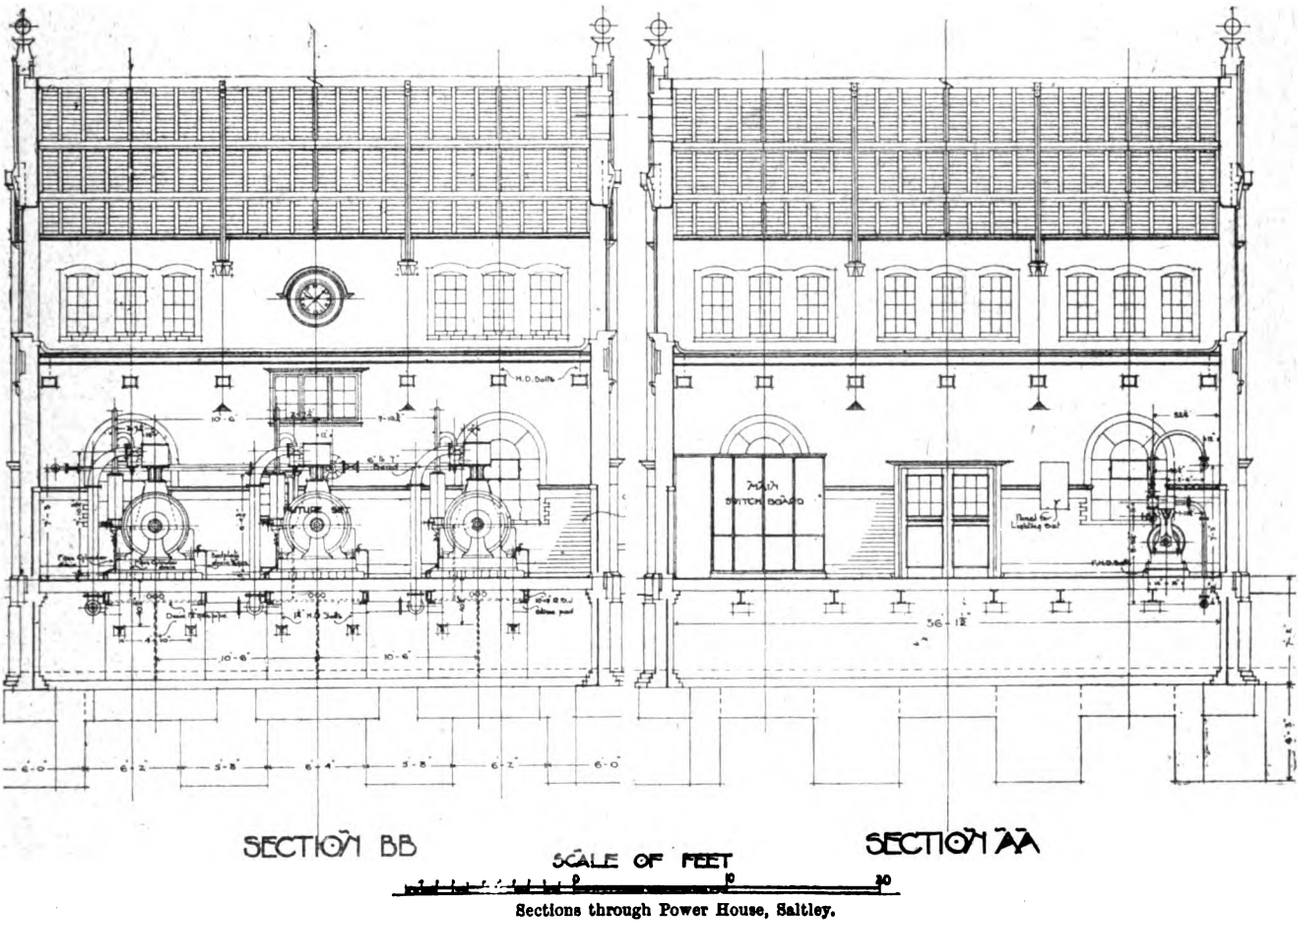
Ground Plan of Refuse Destructor and Power House Buildings, Salford.

Digitized by Google

by ironwork will be finished with glazed brickwork, so that they can be easily kept clean. There will be two refuse hoppers, one over each set of cells, each measuring 32ft. long, 13ft. wide, and 6ft. deep, below the tipping beam. The floors of these hoppers will be constructed of rolled-steel joists and concrete, floated smooth and so placed that no portion of the same shall be in contact with the upper part of the cells, so as to avoid as far as possible the heating of refuse that may be stored in the hoppers previous to charging. The feed doors to the cells will be made to slide and rendered fireproof by means of curved firebrick tiles. Each door will be provided with a water-trough to ensure an inch water seal to prevent the blowing out of sulphurous fumes when the doors are closed. These doors will be worked by means of small hydraulic rams, each working at a pressure of 500lb. per square inch, and operated by levers from the tipping floor. Each ram will be connected up to the three-throw hydraulic pump in the pump-room.

The air heaters will each provide about 1,500 square feet of heating surface. They will consist of 3in. diameter boiler tubes fixed in a vertical position, and secured at their upper and lower extremities to horizontal plates, and entirely surrounded with brickwork braced together in a similar manner to the cells. The hot gases, after leaving the boilers, will be made to pass through these tubes on their way to the economiser and chimney, thereby heating the forced air, which will be made to circulate around the outer surface of the tubes on its way from the fans to the cells. It is claimed by the makers that the introduction of hot forced air into the cells gives an initial temperature of from 300deg. to 350deg. In addition to this, heated air has a greater avidity to absorb moisture; consequently, with the use of hot air the usual drying hearth in the cell is dispensed with. Then, again, with the use of forced air it is easier to regulate the supply of air to the cells to that of the theoretical supply required. With the aid of forced heated air it has been contended for years by those who have closely studied the matter that it is possible to so regulate the forced heated air and the pull of the chimney that a perfect balance of gases can be secured. With this condition existent in the cells cold air cannot enter even with the doors wide open. The fans for forcing the air to the cells will be placed on the tipping floor, immediately over the heaters, and in close proximity to the hoppers. It is hoped that by placing the fans on this floor that they will greatly assist the circulation and the removal of foul air in this part of the buildings. The fans will be connected down to the heaters by means of square steel tubes. Each fan will be 66in. diameter, in order that they may be run at a comparatively low speed, and so that differences in volume can be obtained without much fluctuation in wind speed. The fans will be coupled up to and driven by entirely enclosed self-oiling Belliss engines of 12 b.h.p. each. These fans will be of sufficient capacity to enable 60 tons of ordinary house and shop refuse to be burned in 24 hours on one set of four cells, which is equal to 56lb. per square foot of grate per hour. The makers guarantee that when eight cells and two boilers are in use under ordinary conditions, that the plant will evaporate not less than 9,000lb. of water when the furnaces are fed at the rate of 8,000lb. of refuse per hour.

The first floor of the destructor house will contain the refuse hoppers, the air-fans and engines, the tipping area, and a staircase down to the clinkering area. The tipping area will measure 104ft. long and 27ft. wide, and in addition to this, between the two hoppers there will be an enclosed area 26ft. long and 16ft. wide where it is intended to place the fan and engines.



Sections through Power House, Saltley.

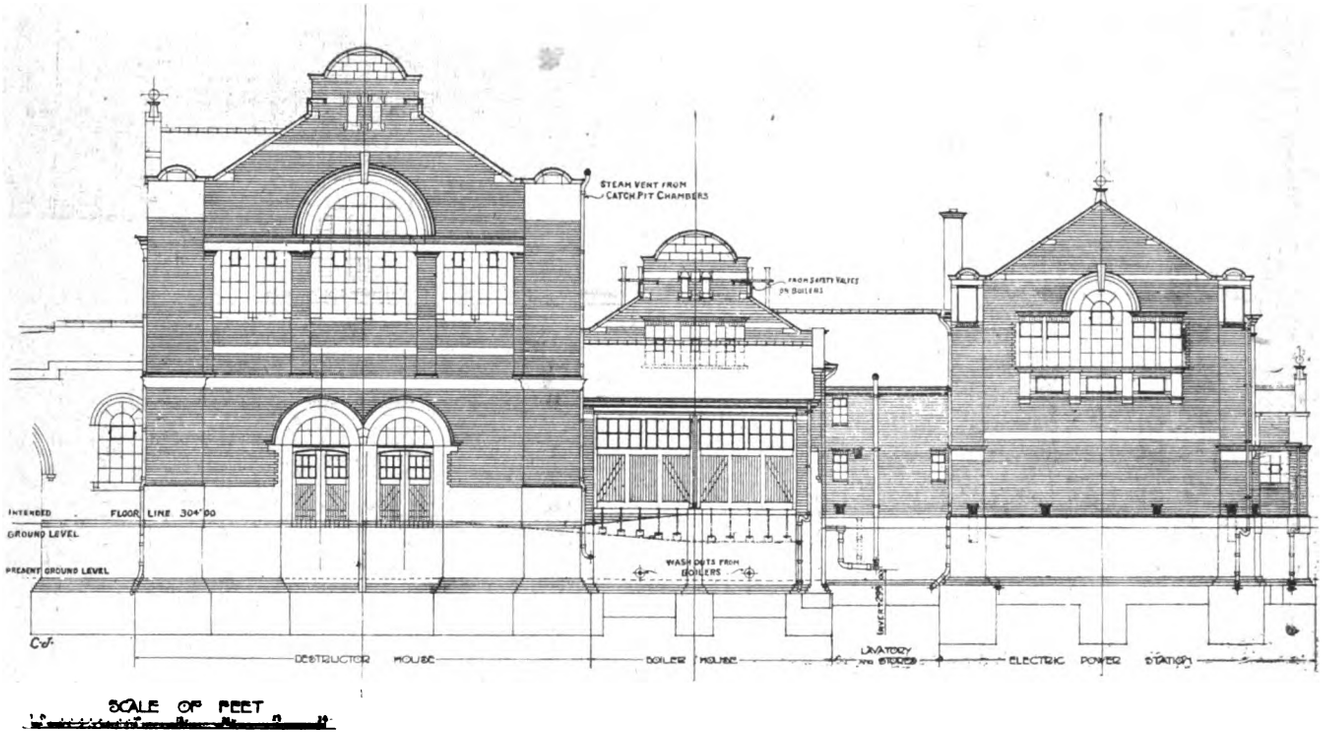
Leaving the destructor house, we next come to the boiler-house. This building measures internally 73ft. 6in long and 24ft. 6in. wide, and is 13ft. high from the top of the flues to tierod. Accommodation is here provided for three boilers, one economiser (with provision for adding another 64 tubes), and the necessary flues. The flues inside the house are to be of large dimensions so as to secure easy access for cleaning purposes. In the centre of the building will be the main flue running across at a low level from the heater in the destructor house to the economiser. On one side of this flue will be placed two boilers side by side, and on the opposite side will be placed one boiler and the economiser with a by-pass flue between. Openings covered with portable firebrick slabs in chases will be provided between the lower boiler flues and the above main low-level flue from the heater for the purpose of sweeping the soot or dust from the boiler flues into the main flue,

Digitized by Google

and thence to a point in this flue under the destructor-house floor, where it can be hoisted up by means of a small permanent winch and deposited into the clinkering trucks close at hand.

The three boilers, which are to be supplied by Messrs. Taylor and Sons, of Marsden, Yorkshire, will be of the type known as Lancashire boilers, each measuring internally 30ft. long and 8ft. diameter, constructed for a working pressure of 160lb. per square inch. Two of these boilers will be gas fired—that is, they will be connected with the furnaces—while the other will be adapted for coal firing, and will be a stand-by. The gas-fired boilers will be connected to the settling chambers by means of steel rings lined internally with firebricks. Each boiler will be fitted with one Hopkinson's patent "Duad" safety valve for high steam and low water, one Hopkinson's patent "Duplex" safety valve for high steam only, one Hopkinson's patent parallel side blow-off valve, and one Hopkinson's isolation valve. The pressure and water gauges on the gas-fired boilers will be fixed on the sides on Hopkinson's columns C type with guards near the back ends of the boilers facing the destructor house, so they they can be seen from the clinkering area. The gauges on the coal-fired boiler will be placed in the usual position on the firing end in connection with the coal-fired boiler, and at the opposite end there will be a cast-iron storage water tank at a high level to hold 5,000 gallons, which will be supplied from the city main.

The furnace chimney, which will stand on a cement concrete base 36ft. square and 8ft. thick, will be at the end of the boiler-house next the canal. A portion of the main flue from the boiler-house to the chimney for a distance of 28ft. will be increased from 3ft. 6in. by 7ft. 3in. to 6ft. by 7ft. 3in., so as to decrease the velocity, thereby facilitating the settlement of any dust before reaching the chimney. The total height of the chimney above the intended finished ground level will be 165ft., and the internal diameter at the top will be 7ft. Above the foundations the chimney for its entire height will be circular in plan, and the batter on the outside face will be 1 in 40—the bond being three rows of stretchers to one row of headers. The top will be finished with a strong cast-iron casing, bolted together in sections, and filled in on the inner side with brickwork; below this there will be a terra-cotta cornice, and some buff plain brick bands, which should form a pleasing contrast with the brindle bricks which it is intended to use for the facing generally. Internally, there will be a fire-brick lining 130ft. high, 9in. thick for the first 75ft. of its



South-East Elevation of Buildings, Saltley.

together with the feed inlet valve. The feed inlets to the gas-fired boilers will be at the top near the back ends. The valves in these cases will be Hopkinson's patent "accessible feed valves," worked from the clinkering area by means of rods and hand-wheels, the hand-wheel being arranged to be worked adjoining the pressure and water gauges. From this position it will also be arranged to work the flue dampers in connection with the gas-fired boilers. It is intended to set the boilers on Pearson's patent seating blocks with asbestos cushion and to cover them with Pearson's patent firebrick covering blocks laid on a layer of asbestos. The emptying pipes from the boilers will discharge outside the building into catch-pit chambers, constructed for the purpose of arresting any deposit from the boilers which would otherwise be discharged into the drains.

The economiser will be supplied by the Clay Cross Company, Chesterfield, and will consist of 128 tubes 9ft. long, $4\frac{9}{16}$in. diameter, fixed vertically and forced into longitudinal top and bottom boxes in sections forming metal to metal joint. The tubes will be arranged in two groups of 64 each, and connected together with cast iron expansion elbows. Each tube will be fitted with triple scrapers, worked by a small continuous-current electric motor. At the south-east end of the boiler-house will be a stokehole

height, and $4\frac{1}{2}$in. thick for the remaining 55ft. At the top this lining will be finished with a keyed firebrick coping, laid loose on the top of the lining to protect the cavity between the lining and the main wall of chimney. The conductor tape will be $1\frac{1}{4}$in. by $1\frac{1}{8}$in., copper connected at the bottom end to a 3ft. square copper earth-plate No. 16 B.W.G., and finished at the top with a solid $\frac{3}{4}$in. diameter copper air terminal, with $\frac{1}{2}$in. diameter inclined points. The terminal will be fixed to a wrought-iron bracket bolted to the cast-iron casing before referred to.

Having described the boiler-house and appurtenances, we now come to the power station. The front portion of this block of buildings will be taken up entirely by the engine-room on the ground floor, with a basement under of similar area. Between the engine-room and the boiler-house will be a small wing, containing on the ground floor a storeroom and lavatory, with a basement under, and on the first floor a small messroom for the attendant containing a window overlooking the engine-room. The engine-room will be 36ft. long, 28ft. 6in. wide, and 22ft. high from the floor to the tierod. The main front will face north-east, and in the centre of this front will be a small entrance porch or vestibule, to serve as the main entrance to this portion of the scheme, approached from the Board's private road. There will be no communication internally

Digitized by Google

between the power station and the boiler-house, the arrangement between the Drainage Board and the Health Committee being that the production of steam shall be entirely governed by the Health Committee, for which the Drainage Board pay an annual fixed sum.

The generating plant in the engine-room will consist of two three-phase generators, direct driven by Belliss engines, and provision will be made for a third set. The engines will be compound two-crank engines, each capable of developing 175 b.h.p. at a steam pressure of 130lb. per square inch, and the generators will be B.T.H. standard 115-kw., 2,000-volt, 50-cycle, revolving-field, three-phase generators, each equipped with shaft, half coupling, out-board bearing, and direct-coupled exciters. Each of these will be capable of standing an overload of 10 per cent. continuously, 25 per cent. for one hour, and 50 per cent. momentarily. The engine-room will also contain the switchboard. This will consist of four panels of polished marble. Two of these panels will control the generators, and the remaining two panels will be for the high-tension and low-tension feeders. The panels for the generators and the high-tension panel will each be 90in. high and 24in. wide, built up in two sections; the low-tension panel will be 90in. high and 16in. wide. The whole of the electrical work will be carried out by the British Thomson-Houston Company, Rugby. A small lighting set will also be placed in the engine-room for the purpose of lighting the power station and the precipitation tanks at Saltley. This will consist of a single vertical engine by Messrs. Bryan Donkin and Clinch, capable of developing 15½ b.h.p. at a speed of 550 revolutions per minute, when supplied with steam at 100lb. pressure, connected direct to one 10-kw., 220-volt, compound-wound generator, with one field rheostat and multi-contact switch.

The exhaust steam from the engines will be taken down into the basement, and thence to a feed-water heater to be fixed outside between the engine-room and the boiler-house. The class of heater it is intended to adopt will be Webster's vacuum feed-water heater and purifier, with oil separator attached, capable of raising the temperature of about 8,000lb. of feed water per hour from 50deg. to about 206deg. F. and over, when fed continuously with exhaust steam at the rate of not less than 1,400lb. per hour.

The travelling crane in the engine-room will be supplied by Messrs. Higginbottom and Mannock, Manchester. This crane will be capable of safely lifting six tons with all motions worked by hand chains from below. In construction it will consist of two 14in. by 6in. cross steel girders, supporting the necessary travelling and lifting gearing, resting at each end on steel carriages, made up of plates and angles, each carriage being fitted with two cast-iron travelling wheels, 21in. diameter. The usual arches internally for carrying the gantry beams have here been placed outside, in which case the beams and rails will rest on the main walls, which will be carried above the gantry beam by the external arches. This form of construction will greatly add to the appearance of the building, and dispenses with a number of objectionable angles in the engine-room. The engine-room will be ventilated by means of a 16in. diameter electric fan, with motor for 220-volt continuous current, capable of circulating 1,260 cubic feet of air per minute. There will be a glazed brick dado in the engine-room and porch, 6ft. high, and above this the walls will be plastered and colour-washed. The floors will be tiled with encaustic tiles.

It must not be omitted to mention that Messrs. W. Lee and Son, of Aston, Birmingham, are the contractors for the whole of the building work in connection with this joint scheme.

The estimated cost of the whole scheme is made up as follows:

CORPORATION OF BIRMINGHAM.

Destructor house	£4,214	0	0
Inclined roadway and boundary walling	3,767	0	0
Drainage, manholes, etc.	100	0	0
Chimney foundation	650	0	0
Chimney above new formation level	1,149	0	0
Outside flue	147	0	0
Refuse furnaces, air fans and engines, and air heaters	4,244	10	0
Hydraulic rams, pump, and engine in connection with furnaces	355	0	0
Gas and water services and fittings	137	10	0
Heating, calorifier, steam-kettle, oven, etc.	100	0	0
Six clinkering trucks and special design	90	0	0
Tramlines inside buildings for ditto	50	0	0
Steam lay out	120	0	0
Fixing only storage tank, providing inlet and outlet pipes, overflow, etc., and gas and water department work	105	0	0
Two cottages, weigh office, and foundations for weigh-bridge	950	0	0
Weighbidge	57	0	0
Land	800	0	0
Total for Corporation carried to summary	£17,046	0	0

DRAINAGE BOARD.

Boiler-house	£1,190	0	0
Economiser	185	0	0
Three boilers	1,412	12	0
Boiler covering	56	0	0
Steam lay out	1,250	0	0
Power station	1,287	0	0
Two feed pumps	100	0	0
One feed heater	58	0	0
Two generating sets	2,400	0	0
Main switchboard complete, including cable connections	356	0	0
Lighting set	180	0	0
Boundary fencing and entrance gates	60	0	0
Travelling overhead hand crane	128	0	0
Total for Drainage Board carried to summary	£8,662	12	0

SUMMARY.

Corporation of Birmingham	£17,046	0	0
Drainage Board	8,662	12	0
Total cost of scheme	£25,708	12	0

COMPANIES' MEETINGS AND REPORTS.

ELECTRIC RAILWAY AND TRAMWAY CARRIAGE WORKS.

The profits of this Company for the year ending June 30, after paying debenture interest and charging £4,299 for depreciation, were £5,546, and £4,827 was brought forward. A dividend of 5 per cent. is proposed, carrying forward £2,873. The directors attribute the decrease of profits to severe competition and general slackness of trade. The prospects for the ensuing year are, however, more favourable. Mr. Barningham and Mr. Kerr (directors) and Messrs. Chiene and Tait (auditors) offer themselves for re-election.

ABERDEEN SUBURBAN TRAMWAYS.

The half-yearly meeting of this Company was held on Wednesday at Aberdeen, Mr. George J. Walker, chairman, presiding.

The report stated that a net profit of £449. 5s. 3d. had been made on the Company's working for the short period that the lines were opened, and the directors proposed that the balance standing at the credit of the profit and loss account should be carried forward to next account.

The **Chairman**, in moving the adoption of the report, commented upon the harmonious working with the Corporation tramways, to which, he remarked, the Company's service undoubtedly acted as a great feeder. As the Company was only in its infancy, the directors thought it prudent to carry the profit forward. He hoped that before long the Company would be able to run additional cars.

The report was unanimously adopted.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Marcinelle (Belgium).—The Episcopal College require tenders for voltmeters. Tenders by Sept 15.

Tynemouth.—The Corporation invite tenders for a 600-kw. steam dynamo by Sept. 30. See advertisement.

Oviedo (Spain).—The Municipality require tenders for the public lighting of the town for 20 years. Tenders by Sept. 20.

Madrid.—Tenders are required by the Municipality for a number of lamp-posts for one, three, and five lamps. Tenders by Sept. 21.

Arenas de San Pedro (Spain).—The Municipality require tenders for the electric lighting of the town for eight years. Tenders by Sept. 25.

Pretoria.—The Commanding Royal Engineer at Army Head-quarters, Pretoria, is calling for tenders for the electric lighting of cantonments.

Mexico.—The Federal District Railway Company of Mexico require tenders for the electrification of six tramway lines in the town. Applications are to be made direct.

Pangbourne.—Tenders are required for lighting the village during the coming winter, for the Pangbourne Parish Council. Particulars may be obtained of Mr. C. West, jun., clerk.

The Hague (Holland).—The Council of the Hague require tenders for the supply of from 8,000 to 9,000 tons of steel rails, including appurtenances, for electric tramways. Tenders by Sept. 22.

Digitized by Google

Edmonton.—The Urban District Council desire to enter into an arrangement with a company for the exercise of their powers under their provisional order. Tenders by Sept. 27. See advertisement.

Brussels.—The Government Railways require tenders for galvanised-iron wire, telectric cables, copper wire, insulators, etc. Specification No. 32. Tenders by Sept. 14, 11 a.m. Public adjudication at the Bourse, Brussels.

The Hague.—The Municipality require tenders for 8,000 to 9,000 steel rails and accessories for electric tramways. Particulars, etc., may be obtained at the Gemeentewerf Groenewegje, at the Hague. Tenders by Sept. 22.

Belmez (Spain).—The Municipality require tenders for electric lighting of Belmez Pueblo Nuevo del Terrible, and Pennarroya for seven years by Sept. 17. Particulars from the Alcadia Constitutional, Belmez, Cordoba, Spain.

Aberdeen.—The Tramways Committee invite tenders for the supply and delivery of 20 top-deck car-covers. Drawings and specifications may be had from Mr. J. Alex. Bell, city electrical engineer, Aberdeen. Tenders by Sept. 27. See advertisement.

La Paz (Bolivia).—The Municipality require tenders for the electric lighting of the town for 12 years. There is an old central station and water power of 150 h.p. to 200 h.p., which is sufficient for the number of lamps required. Tenders by Jan. 15, 1905.

Sofia.—The District Finance Commissioners require tenders for 50,000 km. 4mm. iron wire, 1 000 km. 2mm. iron wire, 15,000 Parphor insulators (No. 2), and 1,000 iron hooks (No. 2). Five per cent. guarantee required. Estimate. £1,175. Tenders by Sept. 23.

Wallasey.—The Urban District Council invite tenders for the supply and erection of high-tension switchgear (which must be of British manufacture) for a sub-station. Tenders to Mr. N. W. Cook, clerk and solicitor, Public Offices, Egremont, Cheshire, by Sept. 14.

London, S.W.—The London County Council invite tenders for the manufacture, delivery, and erection of three electric car traversers at certain of the Council's tramway depôts in the South of London. Specification, etc., may be obtained at the County Hall, Spring-gardens, S.W. Tenders by 10 a.m. on Oct. 4.

Wrexham.—The Corporation require tenders for erection of overhead line wires to connect electric fire calls with the firemen's houses. Further particulars can be obtained from Mr. W. Sillery, borough electrical engineer. Endorsed tenders to be sent to Mr. Thomas Bury, town clerk, Guildhall, Wrexham, by 12th inst.

Rochdale.—The Tramways Committee require tenders for the wiring of car depôt. Applications, with £1. 1s. deposit, to Mr. C. C. Atchison, borough and tramways electrical engineer, Rochdale. Extra copies 5s. each. Tenders, endorsed "Car Depôt Wiring," to be addressed to the Town Clerk, Town Hall, Rochdale.

Edinburgh.—Tenders will be received for the supply of 600 tons (more or less) of cable ropes, for the Edinburgh and District Tramways Company, Limited. Specification may be obtained of Mr. John E. Pitcairn, general manager, 1, South Charlotte-street, Edinburgh, and tenders must be lodged with him in accordance with specification by Sept. 19.

Tschatschak (Servia).—The Electricity Company Owtschar und Kablar in this town require two turbines of 750 h.p. each, two generators for three-phase currents, and other plant for the erection of a hydro-electric central station, and equipment of lines of distribution within 40 miles, by Oct. 2. Specifications, etc., may be obtained from the Manager of the Company.

India Office, S.W.—The Secretary of State for India in Council is prepared to receive tenders to supply (1) compressed paper blocks; (2) carriage and wagon wheels and axles; (3) electrical plant. The conditions of contract may be obtained on application to the Director-General of Stores, India Office, Whitehall, S.W., and tenders are to be delivered at that office by 2 p.m. on 13th inst. for Nos. 1 and 2, and on 20th inst. for No. 3.

Leeds.—The Guardians invite tenders for the wiring installation and subway and underground concentric mains for the electric lighting to the several proposed new hospital blocks and other extensive existing buildings at the workhouse, Beckett-street, Leeds. Send names to Messrs. Thomas Winn and Sons on or before Sept. 12 when specifications and full particulars will be forwarded. Each application must be accompanied by a deposit of £3. 3s.

Greenwich.—The London County Council invite tenders for the manufacture, delivery, and erection at the tramways electricity generating station at Greenwich of the following plant: two 24in. centrifugal pumps and motors, one 3in. centrifugal pump and motor, two 8in. by 8in. three-throw air-pumps and motors, one 3in. artesian well pump, fixed and rotary strainers, etc. Specifications, etc., may be obtained at the County Hall, Spring-gardens, S.W. Tenders by 10 a.m. on Oct. 4.

West Ham.—The Town Council invite tenders for the supply, delivery, and erection of all poles, fittings, wires, and pillars required for the electrical equipment of approximately 3 miles 3 furlongs of tramway track in the county borough of West Ham. Specification, etc., may be obtained from the Borough Electrical Engineer, Electrical Works, Canning Town, E., on deposit of a £5 Bank of England note. Tenders to Mr. Fred. E. Hilleary, town clerk, Town Hall, Stratford, E., by 4 p.m. on Sept. 13.

London, N.—The Edmonton Urban District Council desire to enter into an arrangement with a company for the exercise of their powers under their provisional order. They are prepared to consider offers based upon certain alternative arrangements, particulars of which are set out in the form of tender. Particulars and form of tender may be obtained at the office of Mr. William Francis Payne, clerk, Town Hall, Edmonton. Tenders must be addressed to the Clerk, and delivered by 12 noon on Sept. 27.

Ilford.—The District Council invite tenders for extensions to buildings at their electric lighting station, Ley-street, Ilford. Plans, specification, and form of tender may be obtained on application to Mr. H. Shaw, A.M.I.C.E., surveyor, Town Hall, Ilford, during the usual office hours, on payment of a deposit of £2. 2s. Sealed tenders, endorsed "Tender for Electricity Station Buildings," must be delivered to Mr. John W. Benton, clerk, Town Hall, Ilford, by 12th inst.

La Rochelle (France).—The Chamber of Commerce will shortly issue tenders for a crane with a lifting power for 30 tons. The beam, or the part which projects over the water or vessel alongside, should be long enough to unload from a point about 26ft. 6in. from the edge of the quay. The height of the distal end above the quay should be 15m. (49·21ft.); the vertical distance between the edge of the quay and that part of the crane directly over it, 8m. (26·4ft.). A locomobile is preferred, but should the conditions be unfavourable for installing such a machine, then a fixed crane would be adopted.

Barking (Essex).—The Urban District Council invite tenders for the construction of light railways as follows: (Contract No. 1 and 1A) rails, fishplates, and bolts; (2 and 2A) permanent way construction); (3 and 3A) overhead line equipment; (4 and 4A) underground feeder cables, etc. Specification may be obtained of Mr. H. Hargreaves, clerk, Public Offices, Barking, Essex, on depositing a cheque for £5 5s. Applicants to state the contract for which they propose tendering. Tenders to Chairman of the Electricity and Tramways Committee, Council Offices, Barking Town, by 12 noon on Sept. 20.

Australian Commonwealth.—Tenders will be received at the office of the Deputy Postmaster-General, Hobart (Tasmania), until noon on Sept 30, 1904, for the supply and delivery at the General Post Office, Hobart, of one multiple metallic branching switchboard. Specifications may be seen at, and tender forms and conditions obtained from, the General Post Offices at Hobart, Melbourne, Sydney, Adelaide, Brisbane, and Perth. Tenders should be endorsed "Tender for Switchboard," and addressed to the Deputy Postmaster-General, Hobart. Tenders may be deposited in the tender-box at the General Post Office, Hobart, or, if sent by post, must be prepaid and registered. Tenderers must state the name of the country in which the switchboard will be manufactured.

London, S.W.—The London County Council require tenders for the manufacture, delivery, and erection at the Council's tramways electricity generating station at Greenwich of two 24in. centrifugal pumps and motors, one 3in. centrifugal pump and motor, two 8in. by 8in. three-throw air-pumps and motors, one 3in. artesian well pump, fixed and rotary strainers, etc. Persons desiring to submit tenders may inspect the drawings and obtain the specifications, bills of quantities, form of tender, and other particulars at the County Hall, Spring-gardens, S.W., upon payment to the Cashier to the Council of £2 deposit. Tenders to be addressed to the Clerk of the London County Council, Spring-gardens, S.W., and marked "Tender for Pumping Plant." No tender will be received after 10 a.m. on Oct. 4.

Madrid.—The call for tenders for the service of the electric lighting of Pueblo Nueva del Terrible and Penarroya was without result. The conditions of tender have therefore been modified in certain respects, and a new adjudication is announced to take place on Sept. 18. Tenders are also required for the supply of 25,000 porcelain telegraph insulators, No. 1 of the Spanish type. Tenders, which must be accompanied by a proof that 5 per cent. of the amount has been deposited, will be received at the office of the Direction General of Posts and Telegraphs, No. 10, Carretas, 2° Madrid, up to Sept. 16. The *Gacetas* containing the above notices may be seen by persons interested on application at the Commercial Intelligence Branch of the Board of Trade, 73, Basinghall-street, E.C., any day between 10 a.m. and 5 p.m. (Saturdays, 10 a.m. to 1 p.m.).

RESULTS OF TENDERS.

Portsmouth.—The tender of W. Cory and Sons, Limited, Mark-lane, London, has been accepted for the supply to the electricity works of Lusdale nuts at 13s. per ton.

Plymouth.—The Education Authority have accepted the tender of W. G. Heath and Co., Frankfort-street, Plymouth, at £550 for electric light installation at the Municipal Technical School.

Baltic House, E.C.—The tender of the Private Wire and Telephone Installation Company, 5, Palmer-street, S.W., for installing electric light, telephones, and electric bells in Baltic House, Leadenhall-street, has been accepted.

Plymouth.—The Council have accepted tenders from the British Westinghouse Company for the construction of steam alternators at a cost of £4,141, and from Messrs. Hewitt and Kellet for boilers and piping to cost £3,228.

Lincoln.—The City Council have accepted Messrs E. Nuttall and Co.'s tender for the construction of the permanent way for the tramways in the High-street; also of Messrs. W. Griffiths and Co., Limited, for the construction of the electric tramways.

Sunderland.—The Council have accepted the tender of Messrs. Stothert and Pitt, Limited, for the supply of electric cranes, capstans, and motors required in connection with proposed new traffic quays in front of the warehouses at the Hudson Dock North.

Wellington (Somerset).—The following tenders have been accepted for electric lighting, wiring, and fittings at Nynehead Court, Wellington, for Mr. G. S. Lysaght:—Stansell and Sons, Taunton, £754; Petter and Sons, Yeovil and Bristol, oil-engine, £257.

Colwyn Bay.—The whole of the contract for the construction of a permanent way, cables, and electrical fittings in connection with a tramway and light railway between Colwyn Bay and Llandudno has been secured by Messrs. F. W. Smith and Co., Limited, electrical contractors, Southport. Nearly £80,000 is involved.

Dartford.—The tender of the Western Electric Company, North Woolwich, at £850. 6s. 10½d., has been accepted by the Dartford

Digitized by Google

Urban District Council for carrying out an extension of underground and pilot cables drawn into existing spareways, and for the laying of private and public lighting cables, together with all necessary roadwork, junction boxes, etc.

War Office.—The Army Council have placed a contract with Geipel and Lange, Vulcan Works, 72A, St. Thomas's-street, Southwark, S.E., for 38 Geipel's patent steam traps, to be fitted at the Royal Gunpowder Factory, Quinton-hill, Waltham Abbey. This is the seventh repeat order which they have received for this factory, which will make a total of 210 Geipel traps fitted there.

South Africa.—Orders are about being placed by the Johannesburg Municipality for switchboards, transformers, and switchgear for the new lighting and tramway schemes. A Westinghouse three-phase induction motor is to be installed at the Knights Deep gold mine. A small alternator, with a direct-coupled exciter, has been ordered through the Crown Agents for the Colonies from Messrs. Mather and Platt, Limited, for shipment to Lagos.—*British South Africa Export Gazette.*

South Africa.—The *British South African Export Gazette* announce the following contracts: "Messrs. W. T. Glover and Co. have, we understand, secured the contract for supplying and laying the cables for the Johannesburg electric lighting and tramway schemes. The value of the contract is considerably over £100,000. A storage battery of 250 central-station type cells has been ordered from the Hart Accumulator Company by the Aliwal North Town Council. Orders have recently been placed in England by the Natal Government for the supply of a quantity of dynamos, wire, lamps, and accessories for train-lighting. The contracts placed with Messrs. John Musgrave and Sons, Bolton, for engine equipment for the extension of the Durban power station are on the point of shipment, while that section entrusted to the Brush Electrical Engineering Company is on the water."

BUSINESS NOTES.

TRACTION.

Huddersfield.—In another column we refer to the Corporation's new enterprise.

Darwen.—The Town Council are considering the question of introducing the regenerative-control principle.

Birmingham.—The site of the old general hospital in Summer-lane is being utilised for the new power station.

Kirkcaldy.—A line of tramway in Dysart, connecting with the Kirkcaldy Corporation system, is reported to be in contemplation.

Sunderland.—The Corporation have decided to introduce covers on their double-decked cars. On one or two routes it will be necessary to lower the road.

Torquay.—The Dolter Electric Traction Company have written to the town clerk as to the probable date when the Corporation will be in a position to supply current for the tramways.

Devonport.—The Board of Trade has approved a set of by-laws for the regulation of the tramways, the chief relating to the limitation of the number of passengers to the accommodation of the cars.

Leicester.—The Aylestone-road section of the Corporation tramways was opened on Monday evening. Substantial headway is being made with the Evington-road, Great Central-street, and Groby-road lines.

Campbeltown-Machrihanish.—A petition is being organised in favour of a light railway between these places, situate in the county of Argyle. An application to the Light Railway Commissioners for powers is pending.

Belfast.—The Corporation have confirmed the Tramway's Committee's recommendation that the overhead system be adopted. We refer in our personal column to the appointment of Mr. Nance as tramways manager.

South Shields.—The question whether the tramway system shall be constructed and worked municipally, or leased to private undertakers, was again before the Corporation on Wednesday. Nothing definite was done, it being stated that the committee appointed to deal with the question expected to present their report in November.

Llanelly.—At a meeting of the Urban District Council last week, it was reported that the British Insulated and Helsby's Cables, Limited, had written stating that they could not see the deputation appointed by the Council pending an appeal which they proposed to make against the judgment of the High Court in the recent action with the tramways company. The remainder of the Council's proceedings were held privately.

Swindon.—Several trials have been made on the newly-constructed system, everything passing off satisfactorily. The Board of Trade inspection is expected to be held on Wednesday or Thursday next, in which case the formal opening will take place on the latter day, but as the drivers are to undergo a short course of training, the service will probably not be opened to the public till a week or two later.

Leeds.—Approval has been given by the Corporation Tramways Committee to a proposal for a special evening class on electricity for tramway employés at the Leeds Institute. The committee offer as an inducement to pay the sessional fee of 5s. for all their men who enter and put in a reasonable number of attendances, the idea of the committee being to technically educate the men a little more in the uses of electricity.

York.—Mr. J. Kincaid, chairman of the York Tramways Company, has written to the Corporation with reference to the present condition of the rolling-stock and property of the company. It has been decided to call a special meeting of the Streets and Buildings Committee to consider the letter, and Mr. Kincaid will be asked to state approximately the sum for which the company would be prepared to transfer their undertaking to the Corporation.

Darlington.—The electric tram system is not yet complete, and the Tramways Committee recommend that a sub-committee be appointed to consider and report upon the delay which has occurred in connection with the contracts entered into with the British Westinghouse Electric and Manufacturing Company and the British Electric Equipment Company. Some time ago the Council authorised the enforcement of the penalties in regard to the contracts.

Accrington.—A report was presented to the Corporation on Monday with regard to the reconstruction of the tramways for electrical traction, provision being also made for certain extensions. The system is at present worked by a company under lease, which expires shortly; and the Corporation contemplate applying for powers to carry on the undertaking themselves. The report advises that the construction of additional double lines should be avoided as far as possible, so as to keep the capital costs as low as possible.

London County Council.—Residents of Brixton have been provided with additional means of access to the City, the London County Council having commenced a through service of electric cars from Water-lane to the foot of Southwark Bridge. For the present the service will be confined to between 7 a.m. and five minutes to 10 a.m., and between 3.30 p.m. and four minutes to 8 p.m. Another route has also been opened up between Asylum-road, Peckham, St. George's Church, and Southwark Bridge. This is continued throughout the day.

Rochdale.—The Board of Trade inspector examined the short length of new tramway along Oldham-road from the High Level-road to King's-road at the end of last week. After traversing the route in one of the new double-decker, single-truck cars, he expressed himself satisfied and sanctioned immediate running. The length, which is laid with double track the whole distance, with interlacing lines over Lock Bridge, covers 5 furlong 2·3 chains. A maximum speed of 12 miles an hour was fixed, and later in the day the line was opened to the public.

Southport-Blackpool.—It is reported that the financial difficulties connected with the tramways track which is to cross the Ribble estuary near Lytham, and thus connect Southport, Lytham, St. Anne, Blackpool, and Fleetwood by tram, have been satisfactorily arranged. Sir Hiram Maxim is the chief supporter of the scheme, and the firm of Vickers, Maxim, and Co. are to construct the transporter bridge over the trained channel to the land on each side of the Ribble. Tenders have been invited, and there is every prospect of an early start being made on the work.

Liverpool.—A conference is to be held between the Tramways, the Estate, and the Health Committees in relation to the proposed tramway along Edge-lane. The point at issue is whether a large sum shall be spent upon road widenings to permit of a double line. At Wednesday's meeting of the Corporation a councillor enquired whether the Tramways Committee had considered the advisability of extending the tramway to the Calderstones estate. The Chairman replied that the committee had various extension schemes under consideration, which would be brought before the Council at the earliest possible date.

Manchester.—A meeting of the Corporation is to be held during the first week in October to deal with the question of the provision of electric tramways in the Bucklow and the Cheadle and Gatley rural and urban districts. It is proposed to pass resolutions giving notice to the Manchester Southern Tramways Company that the Manchester Corporation intend to exercise the powers and assume the obligations conferred or imposed on the company by the Southern Tramways Act of 1903 in relation to the construction, maintenance, and user of so much of the tramways authorised by that Act as are situate in those districts.

Worcester.—At its meeting on Tuesday the Town Council adopted revised by-laws to meet the altered conditions of the conversion from horse to electric traffic. Considerable discussion took place as to the efficiency of the tram service in the city, and the company were urged to carry out their undertaking to provide a 10-minute service throughout the whole of their city system. The chairman of the Electricity Committee pointed out that at present the demand for current was only half what was expected, and the committee were bound to take steps to utilise the surplus power in other directions. A proposal to prohibit the running of trams on Sundays was lost.

Blackpool.—At Tuesday's meeting of the Council it was reported that the receipts for the last two months had increased by £3,554 over the corresponding period of last year. A comparison of the expenditure during the same periods showed that in 1903 the wages were £2,112, and the electricity £1,850, a total of £3,962; while this year the wages during the two months were 2,153, an increase of £41, and electricity £1,821 a decrease of £228, despite the fact that the Corporation has run 17,696 more miles and carried 536,675 more passengers. The engineer attributed the decrease in the cost of the electricity to smaller leakage consequent upon the new lines of tramways and the drier summer. There was still the interest and sinking fund charges on the new tramways to take into consideration, however. The system of tram contracts came under review, and the opinion was expressed that the system should be thoroughly revised.

Derby.—The Board of Trade inspector, Major Pringle, visited Derby on Wednesday afternoon and inspected the reconstructed routes. A couple of special cars were chartered, and upon them travelled the Mayor (Councillor C. Boam), the chairman and vice-chairman of the Tramways Committee (Alderman F. Duesbury, J.P., and Alderman P. W. Spriggs), the town clerk (Mr. G. Trevelyan Lee), the borough surveyor (Mr. John Ward), the electrical engineer (Mr. T. P. Wilmshurst), the tramways manager (Mr. F. Harding), and other members of the committee and officials. The lines run over were Bateman-

Digitized by Google

street, Douglas-street, and Dairyhouse-road; Babington-lane, Normanton-road, and Dale-road; and Burton-road. The inspection proved quite satisfactory, and it was anticipated by last evening the system would be in full working order. The Mayor has invited the whole of the drivers, conductors, and general staff, who number close upon 200, to dinner, in commemoration of the opening of the new system.

Petrol-Electric Cars.—We are informed that, in spite of very severe competition from manufacturers in America and other countries, the Wolseley Tool and Motorcar Company, Limited, of Adderley Park, Birmingham, have secured an order for a large six-cylinder petrol engine to develop at normal revolutions 140 b.h.p. The order has been placed by the General Electric Company, of Schenectady, New York, for the first of their new petrol-electric railway coaches. Very considerable interest has been manifested in America, as elsewhere, in the extensive experiments of the North-Eastern Railway Company with their petrol-electric automotor railway coaches. These first two coaches have now passed through all their extensive series of tests, and are running in public service between Scarborough and Filey with every satisfaction. It will be remembered that the "Wolseley" Company supplied two special 90-h p. petrol engines for these coaches after experiments had been made with several other types of motors. The North-Eastern engines have four cylinders 8½in. bore by 10in. stroke. The new ones for America are to be 9in. bore by 10in. stroke, six cylinders. It is especially satisfactory to the "Wolseley" Company to feel that as a result of their enterprise in supplying a special design for the North-Eastern Railway Company's experiments they have secured this order from America. It is understood that after the experimental run of this first engine orders for a further considerable number of engines will be placed with the Birmingham company.

Halifax.—The Tramways Committee ask authority to construct tramways from the present terminus at Jerry-lane, Sowerby Bridge, to Style-bank, Triangle, at an estimated cost of £4,200, "on condition that the Sowerby Urban District Council agree, as far as they legally can, to forego rating the tramway lines in their district for a period of five years." The question of recognising distinct departments in the Halifax tramways system, so that in the absence of the general manager responsibility can be fixed on the head of each department, has for some time past been engaging the attention of the committee. A report of a sub-committee has received the full committee's sanction, and will be brought before the Council at their October meeting. The Tramways Committee are to be duly represented in the new Bill which the Corporation is promoting, but the only fresh powers that they are seeking are for West Vale to Elland, and for three very short lengths. One of these latter refers to Thrum Hall-lane for football traffic, and the other two are to enable the committee to establish a connection with the navigation yards at Halifax and Sowerby Bridge. The committee also propose to vary the Wheatley route, and instead of going round by Shroggs Park, to turn up the Wheatley-lane. They will apply, too, for a revival of the powers which have lapsed down Salterhebble Hill. A start will be made in a day or two with the relaying of the whole line from Skircoat Green to the brewery. The reason is that the joints have given way in consequence of their being laid only on sole-plates instead of having anchor joints.

Bury.—At last Friday's meeting of the Tramway Committee the borough engineer reported that he expected the Tottington section would be completed in a fortnight's time, but that it depended upon the progress made with the reconstruction of the feeder bridge in Crostons-road as to when the section would be opened. He expected it would be in about three weeks' time. It was also reported that Tottington-road, from Walshaw-road to Whittle-street, would be closed from to-morrow to vehicular traffic, pending the reconstruction of the feeder bridge. A letter was read from the secretary of the St. John Ambulance Brigade, Bury Division, with reference to the provision of rubber gloves on the various sections, and suggesting that a pair of gloves should be placed in each of the brigade's wall boxes. About 20 pairs would be required, and the brigade offered to bear one-half the cost. The committee decided to accept the proposal, and expressed their thanks to the brigade for the suggestion. After prolonged negotiations, an agreement has been drawn up between the Bury and Salford Corporations for the interchange of tramway traffic, and this will be formally signed in the course of the next few days. The Salford Corporation under existing agreements has control of the tramways in Prestwich and Whitefield. The Whitefield tramways were opened 18 months ago, or rather that part of them lying between the Prestwich boundary and the Whitefield railway station. There has been considerable delay in the completion of the lines to the Bury boundary owing to trouble between the Whitefield Urban District Council and the company running the steam trams from Whitefield to Bury. The differences, however, have now been settled, and the Salford Corporation has prepared the track and erected the overhead equipment, and the route will be opened very shortly. The agreement between the Salford and Bury Corporations provides for interchange of traffic on much the same lines as that between the Salford and Manchester Corporations in respect to Bury New-road and Deansgate. The Salford Corporation, however, under the new agreement, will have the right to name the routes in Bury over which their cars are to run, and, further, they will decide upon which of their routes the Bury cars are to run. The Corporation have received a letter from the Salford authorities intimating that the section between Whitefield Station and Unsworth boundary is finished, and has been coupled up to the Bury system, and offering Bury the privilege of at once using the lines and running cars through to Whitefield Station. It appears, however, that the lines have not yet been officially inspected, and it was decided not to adopt the Salford suggestion until the line had been inspected. After that has been done there will be a conference between the Bury and Salford managers as to the running of the cars. It has been decided that the fare from Bury to Whitefield Station shall be 2½d., thus making the fare to Manchester 6d.

LIGHTING AND GENERAL.

Worksop.—The Council are raising £2,000 to complete the electric works loan.

Ilkley.—Mr. Warden Stevens is preparing a report on an electric lighting scheme.

Beaumaris (Wales).—The Council have resolved to apply for an electric lighting provisional order.

Andover.—The Town Council intend to apply to the Board of Trade for an electric lighting provisional order.

Weymouth.—An installation of 60 lights of various power has just been successfully opened at electric lighting station. Mr. W. D. Orchard was the contractor.

Batley.—The Council are reducing the price of electric current for the second and subsequent hours per day from 3d. to 2d. per unit, as from and after Oct. 1.

Redditch.—Contracts have been sealed amounting to £3,000 for boilers and feed-water heaters in connection with the electric light undertaking extension.

St. Helens.—The report of Mr. J. Brown, the borough treasurer, shows a considerable increase of £6,883 on the balance of assets in the electricity accounts.

Exmouth.—The question of the best and cheapest mode of lighting the esplanade is before the District Council. The Council have obtained a provisional order.

Buralem.—Sanction has just been received to a loan of £15,700 for the purpose of extending the workhouse, which includes the provision of the electric lighting plant.

Maryport.—The Urban District Council have asked for an extension of the time for carrying out the provisions of the provisional order for electric lighting which they obtained some time ago.

Londonderry.—A test and inspection of the Corporation electric light and power works and the switching on of the private supply took place last night at the electric station, Strand-road.

Felixstowe.—The Lighting Committee have asked the Suffolk Electric Supply Company to name a cash price at which they would sell to the Council the Felixstowe portion of their undertaking.

Bury.—The Electricity Committee have resolved that a supply of electricity to the new workhouse hospital be given upon payment of a flat rate of 3½d. per unit with a minimum annual payment of £200 for a period of 10 years.

Falkirk.—The new poorhouse, which is to be opened next month, has been fitted with 450 lights for an installation of electricity, which is to be taken from the Corporation. Messrs. Thomson and Co., electrical engineers, Falkirk, fitted up the premises.

South Metropolitan Electric Light and Power Co.—The debenture stock transfer register of the above company will be closed, as from the 17th to the 30th inst., for the purpose of preparing interest warrants for the above stock, payable Oct. 1, 1904.

Tuition by Correspondence.—We are asked to draw attention to the fact that electrical and mechanical engineering is taught by correspondence by Prof. A. Jamieson, M.I.C.E., Kelvinside, Glasgow, and students are prepared for examinations and situations.

Stock Exchange.—Application has been made to the Stock Exchange Committee to appoint a special settling day in and to grant a quotation to the London Electric Supply Corporation's further issue of 10,000 6 per cent. preference shares of £5 each, fully paid.

Carron.—The Carron Company are engaged on an extension of the electric lighting of their works at Carron. This is part of a large scheme by which it is hoped to light the entire works. The sections to be lit are those in which it is necessary meantime to burn gas during the day.

Fareham.—The Electric Lighting Committee in their last report state that the new boiler has been built, tested, and found satisfactory. The question of extending the mains to Catisfield has been considered, but as the demand for electricity was not large the committee thought the Council would not be justified in proceeding with the work.

Sale of Plant.—The electric plant at Broomhill, Woodside-lane, North Finchley, N., will be sold on Sept. 13. A catalogue may be obtained from Messrs. Brackett and Sons. For particulars of this and other sales, including the sale of a business, see advertisement columns, also for details of an important sale of plant by tender by the Sunderland Corporation.

Hebden Bridge.—The minutes of the Electricity Committee, submitted at the last District Council meeting, stated that there are at present 2,150 electrical lamps connected. The consulting engineer (Mr. Emmott, Halifax) was empowered to prepare specifications and obtain estimates from the leading makers of suction gas plants suitable for generating electricity at the works. It was resolved to call for the £2,260 balance of the sum authorised to be borrowed by the electricity undertaking.

St. Annes.—In his report of work in the electricity department for the month ended Aug. 26, the electrical engineer states that the output from works was: units sold during July, 1903, 43,178; 1904, 49,876; total units sold to July 31, 1903, 104,489; 1904, 175,030; total number of consumers 1903, 194; 1904, 268. The work has progressed satisfactorily during the month, the traction load during August being very heavy. Messrs. Willans have completed the erection of the last new engine and dynamo. Mr. F. Wilson has completed the foundation tank for the cooling tower. The mechanical stoker fitted to No. 4 boiler has been at work some three weeks, and, on the whole, very satisfactorily. Apart from the question of smoke, he found the machine a decided improvement over hand-firing. Several cables are to be extended.

Digitized by Google

Sowerby.—The Parish Council have decided to accept the tender of the Northern Counties Electric Supply Association for lighting the public lamps, the price to be 28s. 6d. per lamp for 1,385 hours, with an approximate 40 c.p.

Stourbridge.—At last week's meeting the Electric Powers Committee recommended that steps be taken to procure an electric lighting provisional order in regard to the parishes of Pedmore, Hagley, Clent, and Belbroughton. After discussion, the Council decided to delete the recommendation from the report.

Aberdeen.—The Gas and Electric Lighting Committee of the Town Council have decided to recommend that the charge for electric light be reduced by ½d. per unit. At present the charge for private lighting purposes is 6d. per unit for the first hour and 2d. per hour afterwards, and for public lighting 6d. and 1½d.

Norwich.—Elaborate changes are in progress just now in the Market-place, consequent upon the approaching migration of the telephone exchange from the Haymarket to the old *Chronicle* offices. It is said that as a final result Norwich will have one of the best equipped and most modernised exchanges in the kingdom.

Keele.—Sanction has been received to the Council's application to borrow £1,000 for the purchase of property in Edinburgh-street, Mason-terrace, and Government-street for the purposes of erecting an electric lighting and general stores depôt. The Board have given the fullest extent—a period of 60 years—for the repayment of principal and interest.

Removal.—The Tudor Accumulator Company, Limited, have removed their offices from 16 to 119, Victoria-street, Westminster, London, S.W. (telegraphic address, "Subconical, London"; telephone, 24, Victoria). We are informed, that to avoid all delay, all correspondence should be addressed as above, and not to the works, from where it has to be forwarded.

Redcar.—Mr. Eldridge has been consulted as to the estimated expenditure of the Council in laying down plant for electric supply. This estimate is £7,050 to £8,530, and before proceeding further the Council desire to find out the probable private consumption. This decision has been reported to the Board of Trade, as the limit of the order obtained has been reached.

Wrexham.—The electrical engineer's report shows that in July, 1904, 17,196 units were used for tramways and 11,705 for light and other purposes, the total consumption being 28,901, as compared with 29,143 in July, 1903. Three new consumers were connected. The committee's report on the proposed extension scheme was discussed at the last Council meeting, but was referred back.

Turton.—At the last meeting of the Urban District Council a letter was read from the Lancashire Electric Power Company, stating that they had decided that their provisional order for the supply of electricity to the Turton district, which would otherwise have come forward at the next session of Parliament, should be postponed for 12 months, in order that the Turton Council might consider the matter.

Pitlochry.—A private company proposes to introduce electric light to Pitlochry and district at a cost given as being equivalent to half the present cost of gas, which is 7s. 6d. per 1,000 cubic feet. They are now obtaining permission to utilise the water at the Falls of Tummell for generating the necessary power. Mr. A. E. Butter, C.M.G., of Faskally, has approved, and a petition to the trustees of Mr. G. F. Barbour, of Bonskeid, is being promoted asking for his consent.

Agency.—The Electrical Power Storage Company, Limited, have appointed Messrs. Saunders, Todd, and Co., of Maritime-buildings, King-street, Newcastle-on-Tyne, their agents for Northumberland, Durham, and the Tees district, and Mr. J. W. Barnard, sole agent for the company's Q and V type cells, has arranged to place the sale of these and small type cells in their hands for the above district, so that Messrs. Saunders, Todd, and Co. may be in a position to deal with all types of storage batteries.

Cardiff.—Tenders have been received for the erection of a sub-station at the docks, and the contract of Messrs. D. W. Davies and Co., Cardiff, has been accepted. The sum sanctioned by the Local Government Board being only £15,000, and the tender being for a larger sum, it has been decided to communicate again with the central authority. The application of Ely Paper Mills for a supply of electrical power will be considered next week. The works will probably consume 2,000,000 units per annum.

Windsor.—Last Friday the petrol in a new motorcar which had just been finished for a private company at the Windsor Electrical Installation Company's works in Peascod-street caught fire, which spread to the car-shed and the cable store adjoining. It was not possible to telephone to the waterworks for more pressure, as the wire had been destroyed by the flames. However, the firemen were on the spot almost immediately, and succeeded in subduing the fire before it could involve the whole of the shed in which the cable is stored.

Willenhall.—The clerk has been instructed to serve upon the Midland Electric Corporation for Power Distribution a requisition requiring them to lay down distributing mains for the purpose of a general supply throughout the whole of the streets in the area of the Willenhall Urban District Council, and, if necessary, to enter into an agreement with the corporation for the supply of electricity for general street-lighting for a term of three years. A notice is also to be served upon the gas company to determine the present agreement with the company as to public lighting. The erection of a destructor is suggested.

Plymouth.—The reduction in the price of current to private consumers came into operation in July, yet the return of the Corporation electricity undertaking for that month shows an increase of receipts over the corresponding period of last year. The total number of units sold in the month was 110,244. Of these the Corporation trams consumed 71,977 units, the Plymouth and Devonport trams 7,051, private consumers 23,197, motors 851, arc lighting 5,510, and miscellaneous 1,638. The estimated receipts for the month were £1,216. In the corresponding period of last year the consumption totalled 97,175, and the receipts were £1,095. The total lamp connections now number 44,359, against 32,554 last year, and the consumers 575, against 439.

Yardley.—At the last District Council meeting a letter was read from the secretary of the General Post Office, London, with regard to the establishment of telegraphic communication by means of electric bell circuits between the fire stations at Sparkhill and a number of fire-alarm posts. The Postmaster-General was prepared to sanction the continuance of the system on the Council entering into an agreement and paying a nominal royalty of 1s. It was explained by the surveyor that the communication was only used by the public to give alarms of outbreaks of fire. He had made enquiries in other parts of the country, and had found that other authorities questioned the right of the Post Office authorities to control the matter. It was decided to leave the subject in the hands of the clerk.

Wycombe.—At the last meeting of the Council, a report was agreed to in which the Electric Lighting Committee recommended a renewal for a term of seven years of the street-lighting contract with the Wycombe Borough Electric Light and Power Company, who have had this contract for the last six years. The number of arc lamps is to be increased from 11 to 12, the position of the additional arc lamp being selected by the authority, and the 279 small lamps will be fitted at the company's expense with new tops to carry ½-ampere Nernst burners giving 70 c.p. The company is to provide the Council at their own cost with a photometer for testing both the arc and Nernst lamps. The fine for an extinction or implied extinction is to be 3d. for a Nernst lamp, and 5s. for an arc lamp. The cost of lighting the lamps is to be as under: 12 arc lamps at £13, £156; 279 ½-ampere Nernst at £3, £837—total, £993.

Beaumaris.—At the last Council meeting Mr. Cownie, manager and secretary of the National Electric Construction Company, wrote proposing a free wiring scheme based upon a charge of 4½d. per lamp per quarter in addition to the charge for current, and stated, as they had now started on the actual construction of the works, the time had arrived to decide whether they could agree upon a scheme satisfactory to all parties concerned. When the Council determined the working agreement—that is, the agreement for the construction and maintenance of the works which had already been completed—they would have the option of purchasing all the installations at their cost price, which, for this purpose, would be fixed at the sum of 15s. per lamp, plus 10 per cent. and less 2½ per cent. per annum for depreciation. If the Council did not exercise their option of purchasing the installations, then they would pay to the company for all unpurchased installations a rental of 4½d. per lamp per quarter in respect of each installation for such period as may be required to complete 25 years from the date each installation was installed. The matter will shortly be discussed by the Council.

Penny-in-the-Slot Telephones.—According to the *Financial Times*, the Liverpool branch of the National Telephone Company states that the system of "penny-in-the-slot" telephones is to be abandoned. The reason assigned for this decision is twofold. The penny-in-the-slot system involves separate switchboards, additional staff, and a differential administration, for which, in the Liverpool head office, there is not physical space at command. Moreover, it does not pay. Penny-in-the-slot subscribers have been charged a subscription of £3. 10s. per annum, and there has been a condition that if the pennies placed in the instrument in the course of a year do not amount to 30s. the subscriber is to make up the difference. This has been found to involve a considerable amount of clerical work on the part of the Telephone Company's staff and some irritation on the part of the subscribers. The Telephone Company now offers in place of the penny-in-the-slot a system known as the X. and Y. Two separate subscribers may use the line in common at a charge of £6 per annum each. The disadvantage is that when one of them is using the line it is blocked to the other; but each, if curiously disposed, can hear the conversation carried on by the other.

Redruth.—The Urban Electric Supply Company are rapidly extending their operations under the management of Mr. F. S. Hanning. Since the official opening of the tramway in November, 1901, the number of consumers of electric light has steadily increased, there being now between 500 and 600, representing the equivalent of 28,444 8-c.p. lamps. The streets are lit with 172 incandescent and two arc lamps, some burning all night and some half the night. For power supply 220 h.p. has been installed, the machinery driven including 30 h.p. for air compressor, 25 h.p. for Roots blowers, power for fans for gorges, fans for cupolas, ore pulverisers, braiders for fuse-making, and engineering works, wood-working machinery, ironmongers' machines, chaffcutters, dough mixers, soda machines, brewery machinery, organ blowing, etc. The Tuckingmill Fuse Works are entirely driven by electricity, and East Pool ore is carried to the Tolvaddon stamps by use of the same power, in specially constructed tram wagons, probably not much under 1,000 tons weekly. The cheaper rate of carriage to East Pool mine will mean something like a saving of from £400 to £500 per annum. An arrangement is contemplated by this mine for the drivage of pulverisers by electricity. A special engine has been erected to drive the magnetic separator.

LIENS REGISTERED.

Edmundsons' Electricity Corporation, Limited.—An acknowledgment of indebtedness, dated Aug. 19, 1904 (supplemental to a trust deed, dated July 10, 1899, and four deeds of acknowledgment, dated respectively April 27, 1900, Aug. 1, 1901, Nov. 14, 1902, and Sept. 28, 1903, securing debenture stock to an amount not exceeding

Digitized by Google

three-fifths of the paid-up capital for the time being), has been registered. Property charged: 130 first mortgage debentures of £100 each of the Winchester Electric Light and Power Company; 150 similar debentures of the High Wycombe (Borough) Electric Light and Power Company; 200 similar debentures of the Salisbury Electric Light and Supply Company; 150 similar debentures of the Ventnor Electric Light and Power Company; 100 similar debentures of the Bromley (Kent) Electric Light and Power Company; 40 similar debentures of the Woolwich District Electric Light Company; 50 similar debentures of the Chislehurst Electric Supply Company; 40 similar debentures of the Newmarket Electric Light Company; 50 similar debentures of the Alderley and Wilmslow Electric Supply Company; and the company's undertaking and general assets, present and future. Trustees: J. Bailey, 102, Eaton-square, S.W.; and the Anglo-American Debenture Corporation, Limited, 75, Lombard-street, E.C. Total amount of debenture stock previously issued, £300,000.

Metropolitan Electric Supply Company, Limited.—A mortgage by sub-demise, dated Aug. 5, 1904 (supplemental to a trust deed dated July 20, 1894, securing £250,000 first debenture stock), and a further mortgage by sub-demise of even date (supplemental to a trust deed dated July 4, 1899, securing £250 000 second debenture stock), have been registered. Property charged in both cases: Freehold hereditaments, 2, 3, 4, 5, and 6, Fisher-street and 63, 64, 65, and 66, Eagle-street, Holborn, comprised in registered title No. 82,208, and leasehold hereditaments in Tower-street, St. Giles-in-the-Fields, comprised in registered title No. 49,994. Trustees for first debenture stockholders: Sir Robert Herbert, G.C.B., 3, Whitehall-court, S.W.; and Sir James Pender, Bart., Donhead House, Salisbury. Trustees for second debenture stockholders: D. Meinertzhagen, 12, Tokenhouse-yard, E.C.; and Admiral Lord J. Hay, G.C.B., Fulmer Place, Fulmer, Bucks.

SOUTHAMPTON ELECTRIC LIGHTING ACCOUNTS.

Herewith are given abstracts of the revenue account and balance sheet of the Southampton Corporation electric lighting department for the year ended March 31, 1904. The capital expenditure to that date was £172,966.

REVENUE ACCOUNT.

Dr. Expenditure.	£	s.	d.

Number of public lamps, 176.

PROVISIONAL PATENTS, 1904.

AUGUST 29.

18628. An improved electric lamp holder or socket. George Benjamin Stern and Albert Cecil Greene, 31, Silver-crescent, Gunnersbury, London.

18629. Movable step for tramcars. Andrew Sclanders Nelson, 65, Chancery-lane, London.

18635. A method of generating electricity. David Cook, 165, Queen Victoria-street, London.

18642. Improvements relating to means for the production and application of electrical resonance. Horace Manders, 48, Dover-street, Piccadilly, London.

18645. Improvements in and connected with movable arms for microphone carriers. Hermann Oppenheimer, 55, Red-cross-street, Barbican, London. (Akt.-Ges. Mix und Genest, Germany.)

18683. Improvements in and relating to the control of alternating-current electric motors. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

AUGUST 30.

18704. Improvements in or relating to electrical circuit breakers and automatic switches. The Electric and Ordnance Accessories Company, Limited, and Robert Frederick Hall, 24, Temple-row, Birmingham.

18756. Improvements in or relating to street railway cars. Charles Goehring, 46, Lincoln's-inn-fields, London. (Date applied for under Patents Act, 1901, May 21, 1904, being date of application in United States. (Complete specification.)

18764. Improvements in automatic car-couplers. Andrew Jackson Beard, 6, Lord-street, Liverpool. (Date applied for under Patents Act, 1901, Sept. 2, 1903, being date of application in United States.) (Complete specification.)

18766. Improvements in megaphones. Harold Etherington Wilson, 37, Chancery-lane, London.

AUGUST 31.

18792. Improved means for controlling the flow of electricity into third or operative rails or similar appliances for vehicular or other traffic, the said means being also available for signalling purposes. James Graham and Ramsey Kendal, 6, Finkle-street, Stockton-on-Tees.

18801. A mechanical electric governor. Reginald Falshaw, Albert-chambers, Albert-street, Harrogate.

18813. Improvements in or relating to electrical switches and the like. John Taylor, 48, St. Stephen's-avenue, Shepherd's Bush, London.

18819. Improvements in pneumatic brake apparatus for railway and like vehicles. John Wills Cloud, The Westinghouse Patent Bureau, Westinghouse-building, Norfolk-street, Strand, London.

18823. Apparatus for enabling telegraphic and telephonic messages to be received simultaneously over the same line wire. Charles Mark Jacobs, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

18826. Improvements in and relating to fenders for tramway cars. Carl Gabesam, 81, High Holborn, London.

18827. Thermostatic electric circuit controller. Christian Klopfenstein and Godfried Klopfenstein, 81, High Holborn, London. (Complete specification.)

18831. Improvements in and relating to telegraphic and like electric circuits. William Kent Kise, Fife House, Kingston-on-Thames.

18840. Improvements in and relating to processes of electro-deposition. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

18841. Improvements relating to electric transformers. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

18842. Improvements in polarity indicators. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

SEPT. 1.

18855. Improvements in or relating to wires or conductors for electrically propelled tramcars and other vehicles. Richard Green, 36, Temple-street, Birmingham.

18882. Light regulator for electric railway cars. Ettore Arturs Kerbaker, 4, Adelphi-terrace, London.

18908. Improvements in and relating to electric time-recording mechanism and apparatus. Marshall Kelly, 60, Queen Victoria-street, London. (Complete specification.)

18910. Improvements in electrical heaters. Lovel Bearse Pemberton, Norfolk House, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, Jan. 4, 1904, being date of application in United States.) (Complete specification.)

18919. An improved terminal or coupling for electric cables. William Middleton and John Yule Middleton, 18, Buckingham-street, Strand, London.

18920. Improvements in and relating to the manufacture of electrical insulating and non-heat conducting compositions. Henry Harris Lake, 7, Southampton-buildings, Chancery-lane, London. (Société Anonyme Matthey et Cie., Switzerland.)

SEPT. 2.

18926. Terminal connections. Herbert Ernest James McDermott, 168, Plumstead Common-road, Plumstead, Kent.

18937. Improved means and appliances for operating electrolytic cells. James Hargreaves, May Villa, Peel House-lane, Farnworth Within, Widnes, Lancashire.

18942. Improved means for advertising on electric tramcars. Richard Thomas Simcock, 128, Colmore-row, Birmingham.

Digitized by Google

18949. A safety guard for conductor or live rails on electric railways. George Digby Sale, 154, St. Vincent-street, Glasgow. (Complete specification.)

18959. Improvements in electric lamps. Owen David Lucas, 39, Victoria-street, London.

18971. A new magnetic mechanical movement. Henry Stewart Anderson, 6, Bream's-buildings, Chancery-lane, London.

18979. Improvements in or relating to electric traction. Robert Stewart Clouston, 111, Hatton-garden, London.

18987. Improvements in systems of electrical distribution. Percy Holbrook Thomas, Westinghouse Patent Bureau, Westinghouse-building, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, Sept. 4, 1903, being date of application in United States.) (Complete specification.)

18988. Improvements in safety apparatus for tramcars and other like vehicles. Ethelbert Adolphus Stanley and John Edward Anger, 6, Lord-street, Liverpool.

18991. Improvements in systems of electrical distribution. Percy Holbrook Thomas, the Westinghouse Patent Bureau, Westinghouse-building, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, Sept. 4, 1903 being date of application in United States. (Complete specification.)

SEPT. 3.

19009. Improved means of rectifying alternating current, named "aluminium rectifier." Frank Stewart Porah and Sydney George Livett, 62, Theobald's-road, Bedford-row, London.

19034. Improvements in wall plugs for attachment of electric fittings and the like. John Bramwell Haynes and John Hincheliffé, 8, Quality-court, Chancery-lane, London.

19061. Improvements in instruments for calculating electric conductors and problems generally where all but any specific one of the members of a simple algebraic formula are known, as, for instance, Ohm's formula $C = \frac{V}{R}$. Harold Thornthwaite Hincks, 6, Lord-street, Liverpool.

COMPLETE SPECIFICATIONS ACCEPTED

To be published Sept. 22, 1904.

1903.

18581. System for electric lighting of railway trains. Leitner and Lucas.

18745. Excess indicators for use with an electric current. Atkinson.

19172. Apparatus for controlling the working of electrically driven cars. Siemens Bros. and Co., Limited, and Lydall.

19454. Operating vapour electric lamps from an alternating-current source. Weintraub. (Date applied for under International Convention, Oct. 18, 1902.)

20634. Lamp casings and reflectors principally for incandescent electric lamps. O'Brien and Rottanzi.

22968. Multipolar electric generators and motors. Boyden.

22997. Controlling devices for electrically propelled vehicles. Carolan. (General Electric Company.)

23170. Car and line indicators for street railways. Haggerty.

23443. Electrometers. Crompton and Co., Limited, and Price.

25199. Switches for use in connection with the electrical ignition systems of motor cycles and for analogous purposes. Sangster.

1904.

7980. Electric fuses or cut-outs. Mercadier. (Date applied for under Interntional Convention, April 7, 1903.)

12755. Coin-freed apparatus for supplying a current of electricity to persons using it after the insertion of a predetermined coin, and for indicating the strength of the current supplied. Carter and Leheup.

14221. Galvanic batteries. Dreibholz.

14366. Starting resistances for electric motor commutators. Latour. (Date applied for under International Convention, June 27, 1903.)

15467. Vapour electric conductors. Kruh. (Date applied for under International Convention, July 11, 1903.)

NOTES.

Faraday House.—On Monday next Mr. W. R. Cooper, M.A., B.Sc., M.I.E.E., will commence a course of lectures to the senior students upon "Secondary Cells."

Institution Journal.—We have received a copy of the Institution *Journal*, dated August, which contains Mr. Siemens's paper on "High-Speed Electric Railway Experiments on the Marienfelde-Zossen Line," with the discussion; "A Theoretical Consideration of the Currents induced in Cable Sheaths, and the Losses occasioned thereby," by M. B. Field, with discussion; "The Equipment of an Engine Test-House," by R. K. Morcom (Birmingham Section), with discussion; "Mersey Railway Multiple Control," by H. L. Kirker (Manchester Section); "Description of the Electrical Equipment of an Engine Works and Shipyard, with notes thereon," by H. O. Wraith (Leeds Section), with discussion; and "Some Uses of the Oscillograph," by D. K. Morris (Birmingham Section.)

Electricity and Agriculture.—A paper on this subject was recently presented by M. Emile Guarini to the Belgian Society of Engineers and Manufacturers. The author considered that the application of electricity in this connection would extend more when electrical energy was produced at coalfields and distributed to farms by wire, but in the meantime electricity can be generated on the farm by water power, steam, gasoline, gas, wind, and sun motors. A continuous current is best for farms, and if the current is sent a long way to the farm as an alternating current, it should be transformed into a continuous one. The electric motors used ought to be portable, so as to be placed alongside the plough, thresher, straw-cutter, pump, chopper, shearer, churn, etc. Electric is more economical than hand churning. The author added that electricity can be used for lighting fields to permit of night work, for heating incubators, for hot-air fans, for carbonising peat into fuel, and other purposes.

Influence of Pressure on the E.M.F. of Gas Electrodes.—Mr. Theodor Wulf contributes some notes on this subject to the *Zeitschrift Physikal Chemie.* The decomposition point observed galvanometrically is the point at which the discharged gas ions dissolve appreciably in metal and electrolyte. The point at which bubbles are visibly formed is reached when the gas is evolved from a saturated solution. The latter point is dependent, the former point is not dependent, on the pressure, as might be expected from the fact that the evolution of gaseous bubbles means a large increase of volume, whilst the process of solution in metal or electrolyte does not involve any such great volume change. The two points nearly coincide when the gas in question is but slightly soluble, as, for instance, hydrogen and oxygen at the ordinary pressure. They are quite distinct, however, in the case of a soluble gas, such as chlorine. Helmholtz's formula for the variation of the E.M.F. of the hydrogen electrode with pressure has been verified for the range 1 to 1,000 atmospheres.

The Influence of Frequency on the Electrolytic Action of Alternating Currents.—Some experiments recently described in *L'Electrochimie* would seem to contradict the accepted views on this subject. De la Rive, who made the first researches on alternate-current electrolysis, and all the investigators who followed him found that the weight of the deposit formed at the electrodes diminished rapidly with increasing frequency. The new experiments, however, show that, whilst this is the case with many combinations of metals and electrolytes, there are exceptions to the rule. Thus, iron electrodes in cyanide of potassium show a maximum rate of dissolution at a definite frequency. Platinum, which is practically insoluble in cyanide of potassium, is readily dissolved under the action of alternating currents, and the rate of dissolution was found to rise steadily with the frequency within the limits of the experiment (7 ⁓ to 100 ⁓). Nickel and cobalt, again, have a maximum rate of dissolution at a definite frequency, whilst lead in sulphuric acid is practically unaffected by the frequency.

The Regulation of Induction Motors.—In order to reduce the sudden large rush of current on starting up induction motors, Zani-Mailand suggested the winding of the rotor with two independent circuits—one having a high ohmic resistance, but little or no self-induction, and the other having a negligible ohmic resistance, but considerable self-induction. On starting up a motor of this type most of the rotor current will, owing to its high frequency, flow through the path of high resistance and low inductance. As the speed increases the frequency of the rotor currents falls, and more and more current will flow through the path of low resistance and high inductance, until at full speed practically all the current will flow through this circuit. An improvement has lately been suggested by Zani, says the *Elektrotechnische Rundschau*, by means of which it is only necessary to have a single rotor winding. Three coils are mounted on iron cores and fixed on the rotor: the ends of these coils are connected in series with the three phases of the rotor winding. In principle these coils act as the primaries of transformers, of which the secondary currents are represented by the eddy currents in the solid iron cores. It is found quite satisfactory to omit any separate secondary winding and to merely use solid instead of laminated cores in this way. When the motor has attained full speed, a centrifugal arrangement is made to open the magnetic circuits of the three transformers.

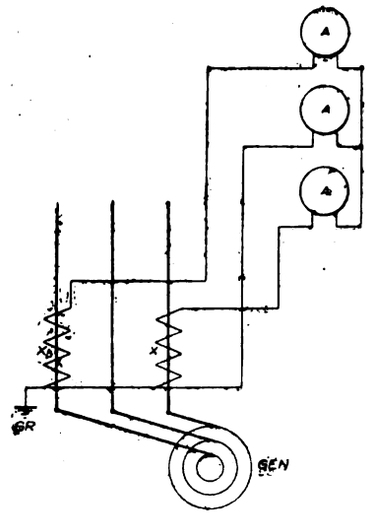
South-Western Polytechnic.—The syllabus for the ensuing session (evening classes) justifies the institution's title of polytechnic, and there can be but few walks in life for which instruction is not afforded. The electrical division, for which the institution is provided with admirable equipment, comprises courses in elementary, intermediate, and advanced electrical engineering, alternating and polyphase currents, electrical design, electrical instruments and lamps, electrical wiring and fitting, and the arithmetic of electric lighting. The instruction combines practical work with lectures, and is designed to, among other purposes, prepare students for the examinations of the City and Guilds of London Institute and of the London County Council. The prospectus of the day college for men and women also exhibits a comprehensive course of training for students above the age of 16. The day school for boys and girls provides admirable tuition in technical and commercial subjects, with a classical side for those who desire to enter the "professions," while girls receive practical instruction in domestic economy. The excellent gymnasium attached to the school shows that the old maxim, *mens sana in corpore sano*, is observed at Chelsea. We just learn, by the way, that Mr. A. J. Makower, of the alternating-current designing department of the British Thomson-Houston Company, Limited, has been appointed head of the electrical engineering department of the institution.

The Past Session.—A review of the electrical measures before Parliament during the late session shows that 58 private Bills for traction, lighting, or power were passed. Of these four were substituted measures and two were abandonment Bills, whilst several of the others were for additional powers. The promoters were pretty equally divided between local authorities and companies,

Digitized by Google

the former being in a slight majority. The rejected Bills included those of the London United Tramways Company, seeking power to construct a system under the Thames at Hammersmith; the East London and Lower Thames Power Company; and the Preston and Blackburn tramway. The Preston and Lytham Bill was withdrawn. Three public Acts were instituted—viz., the Electric Lighting (London) Act, the Expiring Laws (Continuance) Act (including the Light Railways Act, 1896), and the Wireless Telegraphy Act. The Supply of Electricity and the new Light Railway Bills were withdrawn. Electric lighting and provisional orders to the number of 61 and 13 tramway provisional orders were confirmed. Compared with past years, the new tramway schemes were few in number. Under the Private Legislation Procedure (Scotland) Act eight measures were confirmed. The features of the session included the Belfast Corporation Bill, under which the tramway is to be municipalised and electrified; the Tyneside Company's Bill, which ended in an agreement for through running after being referred back to committee; the rejection again of the London County Council's scheme for carrying the tramways over the river; and the passing of the Marylebone Borough Council's Bill, authorising a loan to buy out the lighting company.

Ammeter Connections.—Some particulars of certain features in the ammeter connections of the Union Stock Yards and Transit Company's lighting plant are given in the *Engineer* of Chicago. In connecting the ammeters in the generator circuit, the ground is utilised as a protection, but does not enter into the ammeter circuit proper, the circuit being complete without it. The ammeters are connected on the "open delta" system, as shown in the



accompanying diagram, and are regulated by the principle that the sum of the currents in the three legs is equal to zero, or that the current in one leg is equal to the resultant of the currents in the other two legs, this being an application of the triangle of forces. The parts marked X represent current transformers. There is no occasion to insert one of these in the middle leg or phase, because the third ammeter is connected as explained above, and represents the resultant current of the other two phases, which must be equal to the current in the third leg.

New Publications.—"Modern Electric Practice." (London: Gresham Publishing Company. 9s.) This valuable series has advanced to vol. 4, which is devoted to electric traction, the contributors being Messrs. I. E. Winslow, A. G. Seaman, H. C. Buckmaster, and Phillip Dawson. The different systems of tramway traction are fully discussed, and Mr. Winslow, while agreeing that the surface-contact principle, with its extra capital cost and operating expenses, not to mention other objections, is only justified under special circumstances, is not without hope for the magnetic and electromagnetic types. In another chapter he deals with tramway feeders at considerable length. Mr. Buckmaster contributes a chapter on rolling-stock and equipments, and Mr. Beaumont discusses electric boats and motorcars. In the section on railways Mr. Dawson deals comprehensively with the rival systems of electric traction, and concludes with the prediction that the overhead conductor will eventually supersede the third rail. The *Physical Review* for August has articles on "The Conduction of Electricity in Mercury Vapour," by A. P. Wills; "Some New Theorems analogous to Green's," by P. G. Nutting; "The Elastic Modulus and Elastic Limit of Rubber and their Relation to Change of Temperature," by J. C. Shedd and R. L. Ingersoll; "The Electric Arc," by C. D. Child; "A Study of the Silver Voltameter," by K. E. Guthe; "A New Form of Magnetic Contact Breaker," by J. C. Shedd; "Thermo-E.M.F. of Nickel Nitrate in Organic Solvents," by J. F. Meyer; "The Differential Telephone," and other subjects. We have received the calendar for the ensuing session of the Durham College of Science (London and Newcastle: Andrew Reid and Co. 1s.)

A New High-Tension Electrical Condenser for Continuous Use.—*L'Eclairage Electrique* gives some details of a new type of condenser developed, after lengthy experiments on existing makes, by M. Moscicki, of Fribourg. The ordinary condenser, made up of alternate laminations of conducting material and dielectric, has always been open to numerous objections. It is very liable to break down, especially under continuous use, is considerably affected by changes of atmospheric temperature, insulation considerations entirely prevent any attempt at internal ventilation, and, in spite of its unreliability and rapid deterioration, its first cost is very high. M. Moscicki found that most of the insulation breakdowns in such condensers occurred round the edges of the conducting plates and seldom in the centre. The new type of condenser finally decided upon is of tubular form, and in it the above difficulties are successfully overcome. The length of the dangerous edge of the conducting element can be reduced to a minimum relatively to the total active surface, and the thickness of the dielectric at this dangerous part can also easily be increased when required. It is possible to employ an electrolyte as the conducting element, and in this way obtain a cooling effect which is even superior to that existing in transformers. This system also permits the total amount of dielectric material to be considerably reduced as compared with the ordinary type, and the price compares favourably with that of any other high-tension apparatus. Several types of this condenser have been constructed. With one type a rating of 80 kilo-volt amperes is obtainable from a condenser occupying a space of only one cubic metre, the voltage being 10,000 or over, and the frequency 50. When dealing with voltages below 5,000 or 6,000 it is considered advantageous to raise the pressure of the condenser terminals by means of separate transformers, the price of these transformers being more than compensated for by the reduced cost of the condensers. The new condenser is said to have a minimum efficiency of 99 per cent., which is higher than that attained by any other electrical apparatus.

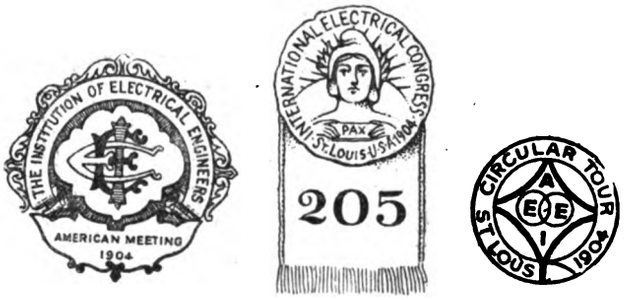
A New Flux Meter.—An instrument for directly measuring a magnetic field of approximately uniform amount by means of an exploring coil of known area and number of turns, is described in a recent number of *L'Electricien*. The instrument is due to M. Grassot, and

Digitized by Google

is similar in construction to a d'Arsonval galvanometer, but with a very weak controlling couple, and consequently a very high damping effect. When a minute E.M.F. is applied to the terminals of such a galvanometer, the coil, having practically no work to do, becomes deflected at such a speed that a counter E.M.F. is set up in it, opposing and practically equal to the applied E.M.F. If α is the deflection and E the applied E.M.F., we may put $\frac{d\alpha}{dt} = KE$, or $\alpha = K \int E \, . \, dt$. During the deflection the galvanometer coil cuts a flux Φ proportional to the deflection, $\alpha = K\Phi$, and the effect of this flux is equal and opposite to $\int E \, . \, dt$ applied at the terminals. If, instead of applying an E.M.F. at the terminals, an exploring coil with a known number of turns is connected to the terminals and is placed in a uniform magnetic field, every variation of this field will set up a corresponding change in the flux through the galvanometer coil—*i.e.*, an E.M.F. will be set up in the galvanometer coil equal to $E = \frac{d\Phi}{dt}$. When the variations of the external field stop, the instrument will have been subjected to a variation $\int E \, . \, dt = \Phi$, so that every variation in the flux through the exploring coil produces a definite deflection of the needle. The instrument is strongly made, and consists of a permanent magnet with an annular iron cylinder between the poles, giving a range of several millimetres with a gap magnetic density of about 1,000 C.G.S. lines per square centimetre. The moving coil of insulated copper wire is suspended in this field by means of a silk fibre attached to a spiral spring, so as to avoid the effects of vibration. The current is led in and out by two spirals of very fine silver ribbon. A needle moving over a graduated scale is fitted, and the exact value of a division, stated as a magnetic flux, is given. This value is about 10,000 C.G.S lines. An exploring coil is supplied with the instrument, having an area of about 10 square centimetres and a number of turns, chosen so that a total flux of exactly 100 C.G.S. lines—*i.e.*, 10 C.G.S. lines per square centimetre—through the coil may produce a deflection of exactly one scale division. For laboratory purposes the instrument can be made still more sensitive by fitting a mirror to the moving coil. It can also be used for measuring the total quantity of electricity passing through a resistance of known amount, and for many of the purposes for which a ballistic galvanometer is usually employed.

Launceston (Tasmania).—The report of Mr. Wm. Corin, the city electrical engineer at Launceston, for the year ended Dec. 31 last records a net profit of £1,115 on the lighting and power undertaking. This is somewhat less than that of the previous year, but the apparent decline is accounted for by substantial reductions in the charges for current and the increase of maintenance and distribution costs, which latter are not likely to advance much further. The revenue totalled £10,692 and the expenditure £5,116, showing a gross profit of £5,576, from which have to be deducted £3,781 for interest and £1,143 contributed to sinking fund. The surplus appearing from this is £652, but it is brought up to the amount given above through sums being credited to the ensuing year's account which properly belong to the period under review. The average cost per unit was 1·736d., and the average price obtained 3·27d. For lighting, power, and heating 453,601 units were supplied to consumers, and 248,550 units were used for street-lighting. The number of customers for private lighting advanced from 1,629 to 1,915, the motors connected increased from 59 to 65, and for energy for heating the consumers rose from 102 to 185. In regard to the future, Mr. Corin, without being unduly optimistic, presents a gratifying picture. Four three-phase generators have just been installed, each of treble the power of the alternators which they displace. With the price of current for motors reduced from 1d. to ½d. per unit after the first 200 units each quarter, and the rentals of motors also reduced, Mr. Corin confidently anticipates that out of the 1,000 h.p. or more now in use in the town the Corporation may count on capturing at least an additional 100 h.p. per annum during the next five or six years, the new charges being such that no user of power can well afford to disregard the service. The use of energy for heating also shows every indication of expansion. In regard to lighting, the receipts to May 31 last show an increase of £431 over the corresponding period of the year under review. Mr. Corin has prepared a table of estimated profits during the next half-dozen years, and, basing his calculations upon very reasonable increases in the consumption of energy, he forecasts a progressive surplus each year, £2,230 being the estimated profit for 1909. The extension of the plant has increased its revenue-producing power threefold without adding a penny to generating costs, and the prospects of the undertaking may be accounted distinctly bright.

The Electrical Congress.—The issue for Sept. 3 of our contemporary the *Electrical World* of New York, which extends a cordial welcome to the visitors to the International Electrical Congress, describes the special badges which have been designed to commemorate the occasion. These consist of the congress badge and the badges of the British,



Italian, and American Institutions. The diagrams reproduced illustrate the two first and the last named of these tokens, and represent their actual size. Our contemporary states that the badge of the British Institution is particularly handsome, and that in the absence of colour but a faint impression of its appearance can be conveyed. The outer rim and the enclosure of the monogram of the Institution are in gilt. The name of the Institute is in gilt letters on white enamel, and the inscription "American Meeting, 1904," is in gilt letters on light-brown enamel. The background of the central monogram is in dark blue. The congress badge is about the size of a cent, irregular in outline, and is struck in bronze finished to a dull colour. The subject is a reproduction of the main feature of the seal of the St. Louis World's Fair. Attached to the medal will be a ribbon carrying a number corresponding to that opposite the name of the wearer in the list of members in attendance to be printed daily in the *Bulletin* of the congress. The ribbons will be of seven colours to distinguish the various grades of members. The badge of the American Institute, which will be presented to those taking part in the circular congress tour, consists of the regular institute badge for full members, enclosed within a ring and bearing the inscription "Circular Tour" on a ground of blue enamel. A highly artistic silver medal, about the size of a quarter-dollar, represents the souvenir of the Associazione Eletrotecnica Italiana. On the face are the initials of the society in relief, enamelled in the red, white, and green of the Italian tricolour; while on the reverse side is a portrait in relief of Volta. The

Digitized by Google

badge is carried by a button to fasten into the coat lapel, and is tied with silk ribbon, also in the tricolour.

The First 40,000-Volt Power Transmission in Europe.—A detailed and well-illustrated description of the 40,000-volt water-power transmission between Gromo and Nembro, in Italy, is given by the *Schweizerische Elektrotechnische Zeitschrift*. The contractors for the work are Messrs. Crespi and Co., of Milan, and the line was opened early in July, and has given every satisfaction since. The present scheme only includes the transmission of 2,000 h.p., but a further 2,000 h.p. from a neighbouring waterfall is to be transmitted along the same line later on. The distance is 20 miles. The present generating station contains three three-phase Escher-Wyss Brown-Boveri turbo-alternators of 1,000 h.p. each, one of them being a spare set. The alternators are standard three-phase 4,000-volt 50-period generators, and the output of each machine is transformed up to 40,000 volts in a single 850-kw. three-phase transformer. Each generator, with its transformer, is dealt with as a single unit, no main switches being provided on the low-tension side between alternator and transformer, although the ammeter and voltmeter transformers and the relays for operating the high-tension automatic circuit breakers are worked from the low-tension side. The transformers are oil-insulated and water-cooled, and consist of three straight limbs side by side, each surrounded by a primary and secondary winding in the form of concentric cylinders. Each transformer occupies a floor space of 5·25ft. by 4·17ft. and a height of 7·1ft. The triple-pole high-tension oil-break main switches have a multiple break on each pole, and are operated by chain gear, either direct by hand or electrically at a distance, by closing a small auxiliary switch, or automatically by means of a double-pole relay actuated by the outgoing current. In this way they act both as main switches and as automatic maximum cut-outs. The three poles of these switches are separated from one another by masonry walls 4·7in. thick. The line consists of three overhead copper conductors, ·256in. in diameter each, and is capable of transmitting 3,000 kw. at 40,000 volts, with a loss not exceeding 5 per cent. The conductors are carried on special porcelain insulators, tested up to 80,000 volts, mounted on wooden cross-arms in the form of an equivalent triangle, with a 33½in. side at an average height of 26½ft. above the ground. The mean distance between posts is 130ft. At the receiving station at Nembro 540-kw. three-phase transformers are employed to reduce the pressure from 40,000 to the distribution voltage of 500. Besides the special high-tension oil-break switches fitted in this station just as in the generating station, a separate emergency triple-pole switch of the horn air-break type is mounted on poles just outside the receiving station for the purpose of entirely isolating this station from the line when required.

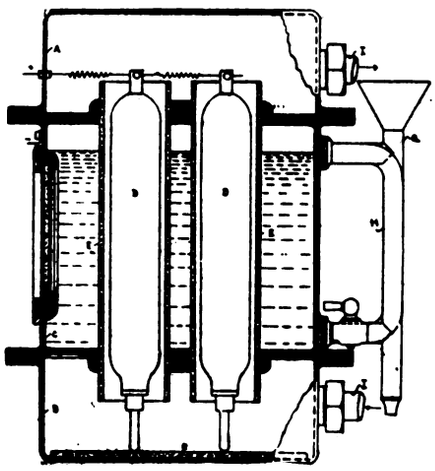
Electricity in South Africa.—The information given in the *British South African Export Gazette* of Sept. 2 testifies to the headway which electricity is making in that part of the globe. The electric light and tramway installation at East London, set up some five years ago, is now working at a profit, and an extension of the tramway is under construction. The system has had a very beneficial effect in extending the area of the town. At Kingwilliamstown an extension of the plant of the King Electric Power Company, Limited, has been decided upon, and it is expected that tenders will be invited at an early date. Terms having been arranged between the Kimberley Corporation and Messrs. Gibson Bros., the proprietors of the tramway to Beaconsfield, the system is to be converted to electric traction on the overhead system, and extended to Alexandersfontein, some four miles beyond the present terminus. It is proposed to secure energy from the De Beers works. Negotiations are also proceeding between the Beaconsfield Town Council and the De Beers Company for the supply of current for lighting that town. The Council contend that current should be supplied on the same terms as it is to Kimberley—6d. per unit. The Council will have to undertake the installation of distributing apparatus, involving considerable orders for mains and fittings. The short line of electric tramway recently constructed at Lorenco Marques by the Delagoa Bay Development Corporation, Limited, is meeting with great success, especially considering the comparatively small population, and an extension has been decided upon. The electric lighting service is also greatly appreciated in the town and its suburbs. At Durban, the use of electricity for tramway, lighting, and power purposes has exceeded all anticipations, and repeated enlargements of the plant have been made. The number of orders for current for motors rendered an increase of the engine equipment of the power station necessary, for which purpose Mr. Roberts, the late borough electrical engineer, obtained quotations when he was in England recently. The Potchefstroom Town Council are contemplating the purchase of the light and power company's undertaking, and when the scheme has been carried out improvements and extensions are likely to be taken in hand. The Cape Town Corporation propose to spend £100,000 on electrical works. As there has been opposition from a certain section, the question will be settled by *pléliscite*, which is expected to result in an affirmative vote. An interesting project is under consideration from Umtata, which it is proposed to furnish with a combined electric and water supply by utilising the fine falls of the Umtata River. The consulting engineers are now engaged in preparing the scheme, which is being watched with great interest, as it will be the first installation of the kind in Cape Colony.

Light Motorcar Trials.—We gave last week a summary of the awards for non-stop runs. As the report of the judges remarks, a considerable element of luck enters into such tests; and their verdict upon special features of the cars embodies some interesting points. The 6-h.p. Siddeley and the 6-h p. Wolseleys, which were placed first and second respectively in Class C, come out well all round, both being awarded the gold medal. Their distinguishing qualities were general excellence of design, construction, and workmanship, and efficient hill-climbing. A gold medal is also awarded to the two 7-h.p. Swifts for general excellence of construction and workmanship, hill-climbing, and smoothness of running. Other awards are: silver medal to the two 6 h.p. De Dions for excellence of workmanship, consistent running, and hill-climbing; silver medal to the two-cylinder 7½-h.p. Humberette for general excellence and attention to detail; silver medal to the two 7-h.p. Alldays cars for general construction, neatness of design, and smoothness of running; bronze medal to the 6-h.p. Speedwell for construction and performance in relation to price; bronze medal to the 8-h.p. Brown for the quality and construction of details; bronze medal to the two 7-h.p. Stars for hill-climbing and construction in relation to price; bronze medal to the 9-h.p. Oldsmobile for ease of manipulation and details of construction; bronze medal to the 8-h.p. Prosper Lambert for the design and construction of parts; bronze medal to the 10-h.p. Croxted for performance and construction in relation to price; honourable mention to the 7-h.p. Clyde for low petrol consumption; honourable mention to the 8-h.p. Mobile for its general performance as a four-seated vehicle. A table of petrol consumption shows that the 7-h.p. Clyde averaged 47·3 miles per gallon, and that nine other cars averaged between 30 and 40 miles. On other

Digitized by Google

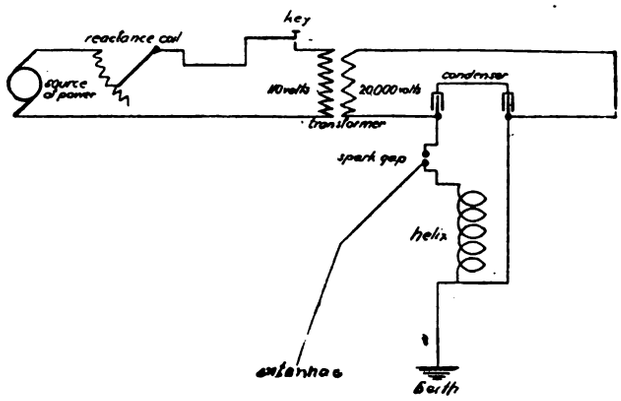
points the judges select the most meritorious cars as follows: absence of noise and vibration, 7-h.p. two-cylinder Swift; ease of manipulation, 6-h.p. Wolseleys, 8-h.p. Brown, 7-h.p. Swifts, and 9-h.p. Oldsmobile; comfort of passengers, 7-h.p. Swifts; hill-climbing, 6-h.p. Wolseley. Of the cars which failed to complete the runs a few were of promising novelty, and some of already proved merit failed through defects not likely to recur. The city of Hereford proved an ideal centre, and the roads selected were admirably suited to the purpose. A noticeable feature was the consistent running of the various teams. The trials brought together a large number of cars, though of few types. The judges observe, in conclusion, that the general design and construction of the cars showed much improvement compared with cars of the same capacity in previous years, and the prices are all lower. While the performances generally were remarkably good, the judges consider that a greater distance than 600 miles is necessary to bring out by automatic records the qualities of the cars and their minor but important details.

Ozone Apparatus.—Among the excellent German exhibits in the electrochemical group at the St. Louis Exhibition is a modern Siemens and Halske ozoniser, a description of which appears in the *Electrical World* of New York. The accompanying diagram illustrates the apparatus as it is used for the purification of water. The upper and lower lids are represented by A and B respectively, the tank is marked C, the inner pole D, E indicates a glass cylinder, F an insulating plate, G and H represent water outlets, and I the ozone pipe. The apparatus consists of a



cast-iron tank closed tightly on the upper and lower end by a case-shaped lid. In this case are mounted 10 glass tubes placed in the upper and lower lids, so that the middle chamber is made water-tight. In service the tank is filled with water, which partially serves for cooling purposes and partially as conductor for the electrical current. In the interior of the glass cylinders are mounted the so-called inner poles in such a way that an equal distance is kept between the same and the glass cylinders. These inner poles are joined together by an electric conductor and connected to one pole of the high-tension transformer; the other pole of the same is connected to the tank, closing the circuit through the water to the glass cylinders. The 50-cycle transformer, which is connected on the primary side to 120 volts and steps the voltage up to 10,000 volts, is of special construction, the primary side being in circuit with a rotating interrupter of the commutator type, with 11 segments, and running at 800 revolutions per minute, being fed through a 110-volt direct-current circuit. The air to be ozonised, after being submitted to a drying process, is brought into the apparatus by a motor-driven blower. The ozone developed by this process accumulates in the upper lid of the tank, and is conducted from there through pipes to the sterilisation tower, where it is forced through the water to be treated. The result of the application of ozone to the water is that practically all bacteria and putrefying substances injurious to health are killed, and the water leaves the apparatus entirely colourless, meeting all requirements of hygiene. The Siemens and Halske Company installed the system on a large scale at the cities of Wiesbaden-Schierstein and Paderborn with excellent results. This type of ozone apparatus is also employed largely for the expeditious bleaching of yarn, which, after being submitted to a short process with chloride of lime, is hung up in a room, where it is treated with the ozone.

De Forest Wireless Telegraph Exhibit.—Some further information respecting the De Forest wireless telegraphic installation at the St. Louis Exhibition is contributed by Mr. Cloyd Marshall to the *Electrical World* of New York. As already announced, this system is operating commercially, besides which long-distance overland experiments are being conducted between St. Louis and Chicago. The greatest undertaking of the De Forest Company has been the erection of a 300ft. steel tower for use as a wireless telegraph station and for observation. Two electric elevators carry passengers to the wireless telegraph station on the 100ft. platform and to the two observation platforms at the top. The power supply is 500 volts direct current, which is transformed by a 70-h.p. motor-generator to 240 volts for driving the elevator motors. At the tower station a 240-volt motor is belted to a 2-kw., 60-cycle, 110-volt alternating-current generator, which is the voltage used for the wireless telegraph transmitter. A transformer



raises the voltages to 20,000. The accompanying illustration shows the arrangement of circuits. The speed with which the Morse key of the transmitter can cut the 60-cycle current into the dots and dashes of the telegraph code is equal to that attained over any land wire. The apparatus is grounded on the frame of the tower itself, which makes the wave length of the antennæ considerably longer than if it were suspended from a wooden structure and the ground made in the ordinary manner. Although the steel frame of the tower renders the station inefficient for wireless telegraphic transmission, the service is stated to have been quite satisfactory, and messages are being received at Springfield, Ill, over 100 miles away. At another station, for which the company erected a 200ft. mast in the most elevated part of the exhibition grounds, 25-cycle alternating current only was available. A 20-kw. Fort Wayne transformer, built for 60 cycles, was found to operate very well on the lower frequency, but there was a drag at the key which would not occur with the higher frequency current. A Wagner motor-generator running on 25 cycles furnished 110 volts direct current used for operating the relay key, which breaks the main circuit. Messages have also been sent from this station to Springfield.

EDDY-CURRENT LOSSES IN THREE-PHASE CABLE SHEATHS.*

BY M. B. FIELD, M.I.E.E.

The extensive use of three-core lead-sheathed cables for power transmissions renders the problem of the determination of the sheath losses due to eddy currents of considerable moment. In a paper recently read before the Institution of Electrical Engineers, the writer published several diagrams showing the general shape of the magnetic field which exists in the immediate neighbourhood of some typical multiphase cables, and also diagrams illustrating the variations in the magnetic field during each cycle. The nature of the currents induced in the lead-sheaths of the cables by these cyclic variations was discussed, and a few elementary calculations of the magnitude of the losses based thereupon. The object of the present communication is to determine more exactly the sheath loss in the case of a three-phase lead-sheathed cable.

Provided the cores are circular in section, and we know that the current distribution over the cross-section of each core is uniform, the problem presents (with certain reservations) no great difficulty. There are, however, two disturbing influences which tend to produce an uneven current distribution in the cores. They are: (1) the influence of the current in each core upon itself, producing the well-known skin-effect; (2) the influence of the current in one core upon the current in the other cores. We may take it, however, that except for the "twist" of the cable cores as explained later, the flow of current in each core is entirely axial, so that, however complicated the actual distribution of current over the cross-section may be, it may be divided into two components—viz, a uniformly distributed current and a system of longitudinally flowing eddy currents. The ohmic losses may then be computed as if these two components existed independently of each other.

Now, the criterion of an eddy-current distribution in a conductor (in which the current flow at every point is entirely axial) is that the surface integral of current density over any transverse section is zero. If $f(x, y)$ be the current density at any instant at the point x, y of a cross-section due to an uneven distribution of current, and if A be the average value of the current density, the actual distribution, $f(x, y)$, may be split up into two components, A and $[f(x, y) - A]$; but evidently $\iint [f(x, y) - A]\, dx\, dy = 0$, where the integration is extended over the core cross-section; $[f(x, y) - A]$ is therefore an eddy-current distribution.

We can further write down the following algebraic equation:

$$\rho \iint A^2\, dx\, dy + \rho \iint \{f(x, y) - A\}^2\, dx\, dy = \rho \iint f(x, y)^2\, dx\, dy - 2A\rho \iint \{f(x, y) - A\}\, dx\, dy.$$

If now ρ represents the specific resistance of the core material, the first term on the left-hand side represents the ohmic loss per unit length at any instant due to the uniform current distribution, A, the second term that due to the eddy-current distribution. The second term in the right-hand side is evidently zero; hence we see that at every instant the actual ohmic loss is equal to the sum of the ohmic losses due to the two components reckoned separately. Thus any effect which causes an uneven distribution of current, is in reality inducing an eddy current.

We have, therefore, to consider not only the eddy currents induced in the sheath, but in the cable cores themselves. It will be convenient to consider the eddy currents induced in the cores under two headings: (1) the self-induced eddy currents, usually termed skin-effect, and (2) mutually induced eddy currents.

Cable cores, when of circular cross-section, are usually built up of a number of strands arranged in concentric layers, the whole having an axial twist or "lay" about the core axis. Now the skin effect in a circular conductor is such as to cause the current to assume a distribution expressed by some function of the distance from the axis only; in fact, the current may almost be considered to flow in cylindric layers, and hence the effect of stranding or twisting the core in reducing the skin-effect will be very small. This, however, is not the case when we consider the mutually-induced eddy currents.

* Paper read before the British Association at Cambridge.

Let us consider two circular cores lying near one another, current being started up one and back along the other (Fig. 1). The generation of the magnetic field due to C_1 will tend to oppose the flow of C_1 and will assist the flow of C_2. The effect will, however, be more marked in the strand a than in the strand b. There will therefore be a tendency for the current-density to be greater in strand a than in strand b. Owing, however, to the fact that the strands are spiralled round the core axis, the strands a and b will have changed places at a point some few inches further along the cable, and the tendency at this point will be for the current-density to be greater in b than in a. If, however, the current-density actually differs at two points of the same strand a few inches apart, current must have entered or left the strand sideways between these two points; but the strength of the current which can thus pass between two contiguous strands depends upon the difference of potential between them and the contact resistance of the current path.

It is easy to see that the difference of potential between two contiguous strands due to the E.M.F.'s induced by the currents in the other cores is excessively small, while the contact resistance will be comparatively high. In paper cables, for example, it is usual to find the resin oil used in the manufacture of the cable has permeated to the centre of each core, thus forming an insulating film between strands. We may otherwise consider the strands a and b as together forming a loop which is threaded by the magnetic lines generated by C_1; the loop is, however, twisted in the magnetic field, and hence the induced E.M.F.'s neutralise each other.

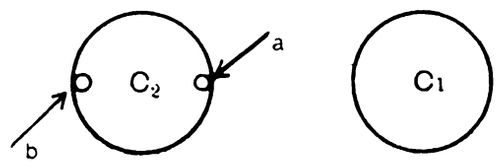

FIG. 1.

While it is evident from the above considerations that in a well-stranded and twisted cable the mutual induction of the cores cannot give rise to such a disturbance that the current-density has different values at different points in any given layer of strands, nevertheless mutual induction may produce in such a core a disturbance similar to skin effect—*i.e*, it may cause the current to be distributed to a certain extent in cylindric layers. For if we compare the E.M.F. induced in a strand lying, say, in the outer layer with that induced in a strand lying in an internal layer, the length of the strand under consideration in each case being that which makes one complete turn or spiral round the core axis, we see that the *mean* E.M.F. per unit length induced in the outer strand is greater than the *mean* induced in the inner strand, hence it is evident that a small effect is produced by the mutual induction exactly similar to the self-induced disturbance, or skin-effect proper. This effect, however, is very small. It is important to observe that in a properly constructed cable the total disturbance of current-density in each core is given by some function of the distance from the core axis, and therefore, as far as the calculation of the sheath losses is concerned, we may consider the current in each core as concentrated at the axis of that core.

In dealing with cores of irregular cross-sections, an exact consideration of the skin effect must of necessity be very complicated. An old patent taken out by Mr. Ferranti specified stranded cores made by twisting together or otherwise combining into one conductor several smaller separately twisted and stranded cores. It is clear that by this means the self-induced as well as the mutually-induced eddy currents may be reduced to negligible limits, and the subsequent calculations in the case of segmental conductors have reference more particularly to cores constructed on this principle. In publishing the following calculation, I wish to acknowledge the very kind assistance given me by Mr. G. F. C. Searle, of the Cavendish Laboratory, Cambridge. After reading the paper above referred to, Mr. Searle showed me the calculation of the induced-current loss due to two parallel conductors of circular cross-section

Digitized by Google

forming a single-phase circuit, symmetrically placed within a thin non-magnetic cylindrical sheath. The following is based upon Mr. Searle's work.

Consider a circuit having one side along the axis of the cable and another side parallel to the axis and passing through the point P (Fig. 2), these two sides being each of unit length, and suppose the circuit be completed by two lines at right angles to the axis. Let k be the total number of lines of force which pass through this circuit due to the currents in the three cores, and let dk be the number passing through it which are due to the currents flowing along the three elements of the cores at Q_1, Q_2, Q_3. Then

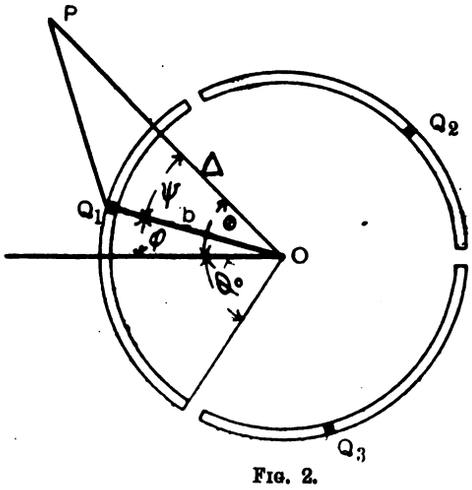

FIG. 2.

$$dk = \frac{b\,db\,d\phi}{5}\Big[A_1 \log b - A_1 \log\Big\{\Delta^2 + b^2 - 2\Delta b \cos\psi\Big\}^{\frac{1}{2}} + A_2 \log b - A_2 \log\Big\{\Delta^2 + b^2 - 2\Delta b \cos\Big(\psi - \frac{2\pi}{3}\Big)\Big\}^{\frac{1}{2}} + A_3 \log b - A_3 \log\Big\{\Delta^2 + b^2 - 2\Delta b \cos\Big(\psi + \frac{2\pi}{3}\Big)\Big\}^{\frac{1}{2}}\Big]$$

where A_1, A_2, A_3 are the current-densities in the three cores in amperes per square centimetre. We shall take

$$A_1 = A_0 \cos pt;$$

$$A_2 = A_0 \cos\Big(pt - \frac{2\pi}{3}\Big);$$

$$A_3 = A_0 \cos\Big(pt + \frac{2\pi}{3}\Big);$$

where $p = 2\pi f$, and f represents the number of cycles per second.

With these values we have at every instant

$$A_1 + A_2 + A_3 = 0.$$

Now when $\Delta > b$, we may write

$$\log(\Delta^2 + b^2 - 2\Delta b \cos\psi)^{\frac{1}{2}} = \log\Delta - \frac{b}{\Delta}\cos\psi - \frac{b^2}{2\Delta^2}\cos 2\psi - \text{etc.}$$

We thus obtain, after simplification,

$$dk = \frac{3\,b\,db\,d\phi}{10} A_0 \Big[\frac{b}{\Delta}\cos(pt-\psi) + \frac{b^2}{2\Delta^2}\cos(pt+2\psi) + \text{etc.}\Big]$$

the terms in b^3, b^6, b^9, etc., vanishing.

In order to find k, we have to integrate this expression over the surface of one of the three cores. We therefore insert $\psi = \theta - \phi$, and for segmental shaped cores integrate with regard to ϕ between the limits $\pm\phi_0$, and with regard to b between the limits b_1 and b_2, and we have:

$$k = \frac{3}{5}A_0\Big\{\Big[\frac{b_1^3 - b_2^3}{1^2\times 3\Delta}\cos\theta\sin\phi_0 + \frac{b_1^4 - b_2^4}{2^2\times 4\Delta^2}\cos 2\theta\sin 2\phi_0 + \frac{b_1^6 - b_2^6}{4^2\times 6\Delta^4}\cos 4\theta\sin 4\phi_0 + \text{etc.}\ldots\Big]\cos pt + \Big[\frac{b_1^3 - b_2^3}{1^2\times 3\Delta}\sin\theta\sin\phi_0 - \frac{b_1^4 - b_2^4}{2^2\times 4\Delta^2}\sin 2\theta\sin 2\phi + \frac{b_1^6 - b_2^6}{4^2\times 6\Delta^4}\sin 4\theta\sin 4\phi_0 - \text{etc.}\Big]\sin pt\Big\} \quad (1)$$

While for cores of circular cross-section of which the area is a, the centres being situated on the centre lines of the segmental cores in the diagram, at a distance b_0 centimetres from the cable axis, we have

$$k = \frac{3\,a\,A_0}{10}\Big[\frac{b_0}{\Delta}\cos(pt-\theta) + \frac{b_0^2}{2\Delta^2}\cos(pt+2\theta) + \frac{b_0^4}{4\Delta^4}\cos(pt-4\theta) + \text{etc.}\ldots\Big] \quad (2)$$

If we neglect all other magnetic forces producing flux through the imaginary circuit except those due to the core currents, the total E.M.F. in volts acting in the circuit will be $10^{-8}\frac{dk}{dt}$. Now any E.M.F. we may consider generated in the side of the circuit which lies along the axis must, owing to the symmetry of the case, bear the same phase relation to the currents in each of the three cores, a condition only possible provided the E.M.F. is zero. Further, the E.M.F. generated in the two sides at right angles to the axis taken together must be zero; hence we may regard the entire E.M.F. generated in the imaginary circuit as existing in that side which passes through the point P.

Moreover, from a consideration of the longitudinal nature of the currents in the sheath (supposed to be insulated), and of their phase change circumferentially, it is clear that the ohmic drop per unit length at every point is equal to the E.M.F. generated in the same length. Hence we have

$$\rho_s u_\theta = -10^{-8}\frac{dk}{dt},$$

where u_θ is the current density at the point θ of the sheath, and ρ_s is the specific resistance of the sheath material.

The average power lost in the sheath per unit length is, therefore, the time-average value of

$$\frac{10^{-16}}{\rho_s}\int_{\Delta_2}^{\Delta_1}\int_0^{2\pi}\Big(\frac{dk}{dt}\Big)^2 \Delta d\,\Delta d\,\theta \text{ watts.}$$

Inserting the values of k given by (1) and (2), we find that for segmental cores the time-average value of the loss, W, in watts per centimetre length of cable is

$$W = \frac{1\cdot 44\,A_0^2 f^2\pi^3}{10^{16}\rho_s}\Big\{\Big[\frac{b_1^3 - b_2^3}{3}\sin\phi_0\Big]^2\log\frac{\Delta_1}{\Delta_2} + \Sigma\Big[\frac{b_1^{n+2} - b_2^{n+2}}{n^2(n+2)}\sin n\phi_0\Big]^2 \times \frac{1}{2n-2}\Big[\frac{1}{\Delta_2^{2n-2}} - \frac{1}{\Delta_1^{2n-2}}\Big]\Big\} \quad (3)$$

where n has the values 2, 4. 5, 7, 8, 10, etc., successively, the intermediate values, 3, 6, 9, etc., not appearing. If τ be the thickness of the sheath in centimetres, and this be small compared with Δ_0, the mean radius,

$$\log\frac{\Delta_1}{\Delta_2} = 2\Big[\frac{\tau}{2\Delta_0} + \frac{1}{3}\Big(\frac{\tau}{2\Delta_0}\Big)^3 + \frac{1}{5}\Big(\frac{\tau}{2\Delta_0}\Big)^5 + \ldots\Big]$$

or $\log\frac{\Delta_1}{\Delta_2} = \frac{\tau}{\Delta_0}$, when the higher powers of $\frac{\tau}{\Delta_0}$ are neglected.

We may furthermore write $\frac{1}{\Delta_2^n} - \frac{1}{\Delta_1^n} = \frac{n\tau}{\Delta_0^{n+1}}$; so that, in these circumstances, the equation (3) becomes

$$W = \frac{1\cdot 44\,A_0^2 f^2\pi^3\tau}{10^{16}\rho_s\Delta_0}\Big\{\Sigma\Big[\frac{b_1^{n+2} - b_2^{n+2}}{n^2(n+2)\Delta_0^{n-1}}\sin n\phi_0\Big]^2\Big\} \quad (4)$$

where n has the values 1, 2, 4, 5, 7, etc., successively.

Owing to the rapidity of convergence of this series, for practical applications all terms except those involving $\sin^2\phi_0$ and $\sin^2 2\phi_0$—*i.e.*, the first two terms when the above expression is expanded—may be neglected.

In the case of circular cores we have from (2)

$$W = \frac{0\cdot 36\,a^2 A_0^2 f^2\pi^3 b_0^2}{10^{16}\rho_s}\Big\{\log\frac{\Delta_1}{\Delta_2} + \Sigma\frac{b_0^{2n-2}}{n^2(2n-2)}\Big(\frac{1}{\Delta_2^{2n-2}} - \frac{1}{\Delta_1^{2n-2}}\Big)\Big\} \quad (5)$$

or, if the sheath be very thin, we have

Digitized by Google

$$W = \frac{0{\cdot}36\, a^2 A_0{}^2 f^2 \pi^3 b_0{}^2 \tau}{10^{16} \rho_s \Delta_0} \left\{ 1 + \Sigma \frac{b_0{}^{2n-2}}{n^2} \cdot \frac{1}{\Delta_0{}^{2n-2}} \right\} \quad . \quad (6)$$

where n has the same values as before, from, and including 2, onwards.

It is instructive to form some idea of the magnitude of the currents flowing in the sheath. We may consider the sheath sub-divided into three segments each subtending the angle $\frac{2\pi}{3}$ at the axis, the segments corresponding as regards position with their respective cores—*i.e.*, the sheath is sub-divided by the three radii defined by $\theta = \frac{\pi}{3}$, π, $-\frac{\pi}{3}$.

The total current flowing in the sheath segment opposite to core 1 will be

$$-\frac{1}{\rho_s 10^8} \int_{\Delta_2}^{\Delta_1} \int_{-\frac{\pi}{3}}^{\frac{\pi}{3}} \frac{dk}{dt} \cdot \Delta \, d\Delta \cdot d\theta.$$

With segmental cores the value of this expression is

$$\frac{6\sqrt{3}\,\pi A_0 f}{5 \times 10^8 \rho_s} \left[\frac{b_1{}^3 - b_2{}^3}{3} \sin \phi_0 \, (\Delta_1 - \Delta_2) + \frac{b_1{}^4 - b_2{}^4}{2^3 \times 4} \sin 2\phi_0 \log \frac{\Delta_1}{\Delta_2} - \frac{b_1{}^6 - b_2{}^6}{4^3 \times 6 \times 2} \left(\frac{1}{\Delta_2{}^2} - \frac{1}{\Delta_1{}^2} \right) \sin 4\phi_0 - \text{etc.} \right] \sin pt \, . \quad (7)$$

While for circular cores with a thin sheath we have

$$\frac{6\sqrt{3}\,\pi a A_0 \Delta_0 \tau f}{10^9 \rho_s} \left\{ \frac{b_0}{\Delta_0} + \frac{b_0{}^2}{4\Delta_0{}^2} - \frac{b_0{}^4}{16\Delta_0{}^4} - \frac{b_0{}^5}{25\Delta^5} + \text{etc.} \right\} \sin pt \quad (8)$$

In each case the current in the sheath segment is in quadrature with the current in the corresponding core. We must thus consider the sheath currents as a *three phase* eddy-current distribution.

Up to the present we have neglected the magnetic forces due to the sheath currents, and it is important to determine to what extent this is permissible. We may consider the magnetic force at any point of the sheath as consisting of a tangential and a normal component. First, with regard to the tangential component; if the diameter of the cable be large compared with the thickness of the sheath, we may consider any small portion as a plane slab subjected to magnetic force parallel to the surface. In these circumstances we know that the magnetic force will be less in the interior than at the surface. If τ be the thickness in centimetres, H_1 the maximum value of the magnetic force at the surface, H_2 the maximum value at the centre of the slab,

$$H_2 = H_1 \frac{2}{\sqrt{\epsilon^{m\tau} + \epsilon^{-m\tau} + 2\cos m\tau}}$$

where $$m = 10^{-4} \times 2\pi \sqrt{\frac{\mu f}{10\,\rho_s}}.$$

It is easy to demonstrate that if $m\tau < 1$ the ratio $\frac{H_1}{H_2}$ is very nearly equal to $1 + \frac{m^4\tau^4}{48}$, and, consequently, as $\frac{m^4\tau^4}{48}$ is small compared with unity, H_2 may be taken as sensibly equal to H_1.

If the material of the slab be lead, and if $f = 50$, $\tau = 1$cm., $\frac{m^4\tau^4}{48}$ is of the order of $1{\cdot}9 \times 10^{-4}$. We may take it, therefore, that the tangential component of the magnetic force within such sheaths as are likely to be met with in cable practice is not affected by the sheath currents in the immediate neighbourhood. Secondly, with regard to the normal component of the magnetic force; let us consider the sheath to be concentrated along a very thin cylinder of thickness τ, radius Δ_0 (the mean radius of the sheath), the conductivity of the imaginary sheath as a whole being equal to that of the actual one.

We will calculate the value of the normal magnetic force at P due to the sheath currents and compare this with the value of the normal magnetic force obtaining at the same point due to the core currents. In order to preserve the convergency of our expansions, we consider the point P (Fig. 3) slightly off the sheath so that O P $= \gamma \Delta_0$ and, $\gamma < 1$, but on account of the continuity of the normal induction this will evidently give us the desired result.

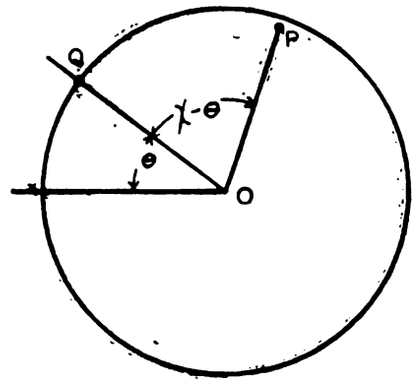

FIG. 3.

We will consider, as before, an imaginary circuit of unit length, one side lying along the axis, one parallel to it and passing through P, the remaining two being at right angles to the axis. The total number of lines, dk', which thread this circuit due to the current in the sheath element at Q will be

$$dk' = -\frac{u_\theta \tau \Delta_0 \, d\theta}{5} \log\{1 + \gamma^2 - 2\gamma \cos(\chi - \theta)\}^{\frac{1}{2}},$$

and the normal induction at P due to this element of current will be*

$$d H_n = -\frac{1}{\gamma \Delta_0} \frac{d}{d\chi} (dk')$$

$$= \frac{u_\theta \tau}{10\,\gamma} \frac{d}{d\chi} [\log\{1 + \gamma^2 - 2\gamma \cos(\chi - \theta)\}] \, d\theta.$$

The total normal magnetic force at P is, therefore,

$$H_n = \frac{\tau}{10\,\gamma} \int_0^{2\pi} u_\theta \frac{d}{d\chi} \log\{1 + \gamma^2 - 2\gamma \cos(\chi - \theta)\} \, d\theta.$$

Inserting the value of u_θ for segmental cores—viz., $-\frac{1}{\rho_s 10^8} \frac{dk}{dt}$, where k is given by equation (1)—we have

$$H_n = \frac{3\pi\tau p A_0 10^{-6}}{25\,\rho_s \gamma} \left[\frac{b_1{}^3 - b_2{}^3}{1 \times 3\Delta_0} \gamma \sin \phi_0 \cos(pt - \chi) - \frac{b_1{}^4 - b_2{}^4}{2^2 \times 4\,\Delta_0} \gamma^2 \sin 2\phi_0 \cos(pt + 2\chi) + , \text{ etc.} \right]$$

We can now make $\gamma = 1$, and we have the normal magnetic force at the point χ on the sheath due to the sheath currents only. The normal component due to the core currents is given by

$$-\frac{1}{\Delta_0} \frac{dk}{d\chi},$$

or,

$$-\frac{3 A_0}{5 \Delta_0} \left\{ \frac{b_1{}^3 - b_2{}^3}{1 \times 3\Delta_0} \sin \phi_0 \sin(pt - \chi) - \frac{b_1{}^4 - b_2{}^4}{2 \times 4\,\Delta_0{}^2} \sin 2\phi_0 \sin(pt + 2\chi) + \text{etc.} \right\}$$

These two series are not directly comparable on account of the different numerical coefficients of the second and succeeding terms, but they are fairly rapidly convergent, so that in any given numerical example it is easy to compare the relative values of the magnetic forces at any point due to the sheath and core currents respectively. If, as an approximation, we compare the first terms of the two series, we find that the self-induced magnetic force is very nearly in quadrature with that due to the core currents, and that for the former to be negligible the quantity

* Positive normal magnetic force is here considered as directed radially outwards and positive current as flowing upwards from the plane of the paper.

Digitized by Google

$10^{-9}\, p \times \frac{2\,\pi\,\tau\,\Delta_0}{\rho_s}$ must be small compared with unity, or the conductivity of the sheath as a whole (centimetres per ohm) multiplied by $2\,\pi\,f$, must be small compared with 10^9. On the other hand, as far as the magnitude of the sheath loss is concerned, it should be noted that, on account of the two magnetic forces being nearly in quadrature, the smaller may be a fairly large percentage of the other without seriously affecting the accuracy of the calculation. Such considerations show that even for such large cables as that considered below (6·8cm. outside diameter) the sheath loss may be calculated without reference to the self-induced disturbance of current density.

Although we have hitherto assumed the sheath to be insulated, we see that the results would be the same if the cable were laid in a semi-conducting medium such as damp earth, provided it be symmetrically surrounded, and the conductivity of the same be not great enough to permit of currents whose magnetic force at any point of the sheath is comparable with that due to the currents in the cores. This will be seen to be true, when it is considered that the distribution of the sheath currents is such as to give zero potential at all points of the sheath.

From the shape of the expression for W, we see that for cables of similar cross-sections the sheath watt-loss at a given frequency and maximum current-density in the cores is proportional to the sixth power of the diameter. This is of the greatest importance, for it indicates that the

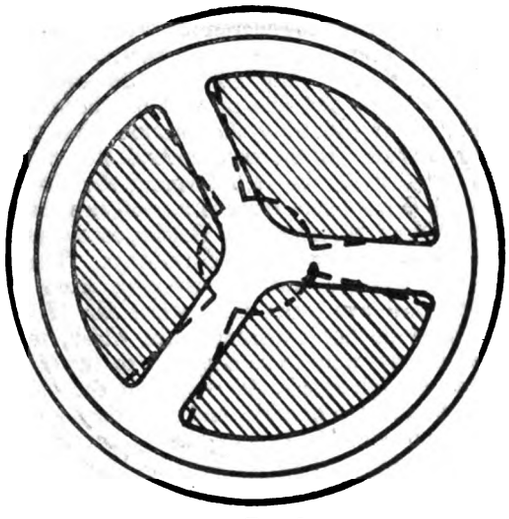

FIG. 4.

sheath loss alone, and apart from all other considerations, would limit the size of economical cables. Indeed, it can be demonstrated very easily that this is true whatever may be the arrangement and shape of cores and sheath, provided the current system be balanced, and that in comparing two cables of *similar* cross-sections the maximum current-density and the phase relations of the various core currents is the same.

We might thus express the sheath loss per mile in a two or a three phase cable of moderate dimensions in the form

$$\frac{A_0^2\, f^2\, d^6}{\rho_s} \times P,$$

where A_0 represents the maximum current-density in any one of the cores, f the frequency, d the external diameter of the sheath, ρ_s its specific resistance, and P is a coefficient depending on the type of cable—*i.e.*, two or three phase, etc.—on the arrangement of the cores and sheath, and the relative proportions of the same, but *not* upon any absolute linear dimensions. Thus, if the values of P be determined for a number of different types of cross-section, we can at once determine the sheath loss in any cable whose cross-section is similar to any one of the types.

We may now, by way of example, consider a definite case. Fig. 4 represents a low-tension three-phase lead-sheathed cable, full size. The full areas (shaded) are the shapes the cores would in all probability take in practice, while the segmental shapes (dotted) are readily amenable to calculation. The segmental section is smaller than the true section by the small obtuse-angled area near the centre. The additional sheath loss due to the currents in these areas, however, is negligible; and we may say the loss calculated on the basis of the segmental sections is slightly less than that due to the dotted sections. The dimensions are: $b_1 = 2{\cdot}5$ cm.; $b_2 = 0{\cdot}8$ cm.; $\Delta_1 = 3{\cdot}4$ cm.; $\Delta_2 = 3{\cdot}0$ cm.; $\phi_0 = 0{\cdot}85$ radians; $f = 50$ cycles per second; $A_0 = 162$ amperes per square centimetre; $\rho_s = 21 \times 10^{-6}$ ohms. Gross area of core (if solid) = 4·7 square centimetres Nett area allowing for stranding = 3·5 square centimetres. A_0 is reckoned on the basis of a solid core, so that the actual current-density in the copper is 223 amperes per square centimetre. This is the maximum value of the sine function, so that the effective value may be taken as 156 amperes per square centimetre (= approximately 1,000 amperes per square inch). Applying the formula above, we find W = 4·19 kw. per mile, it being only necessary to consider the first two terms of the series.

The total effective current per core is 545 amperes, so that on the basis of an ohmic drop of 44 volts per mile the C^2 R loss in the three conductors becomes 72 kw. per mile—*i.e.*, the sheath loss is 5·8 per cent. of the core loss. If, now, we take an extreme case and consider a cable similar, but whose cross-section is of twice the linear dimensions, the sheath loss per mile as given by the formula would be increased sixty-four-fold, while the core loss would be increased only fourfold. It must not be lost sight of, however, that with so large a cable it would no longer be permissible to neglect the magnetic forces in the sheath due to the sheath currents themselves.

Returning to the case represented in Fig. 2, we find that the sheath currents can be considered as a three-phase eddy-current distribution, and the current per phase is calculable from equation (7). It is in the above case 41·8 amperes maximum, corresponding to 771 amperes maximum in each core. As we have seen, the total current in each sheath segment is in quadrature with the current in the corresponding core. Quite apart from the magnitude of the sheath loss occurring in large cables, which might possibly be reduced to reasonable limits by making the sheath sufficiently thin and providing adequate mechanical protection, the above considerations show that as the size increases the mean effective current-*density* in the sheath will rise to a prohibitive figure, a point being eventually reached at which the danger of actually fusing the sheath is introduced.

We have described "skin effect" in a cable-core as a self-induced eddy-current system, the ohmic loss attributable thereto being proportional to the square of the effective current in the core for a given frequency. Lord Kelvin gave formulæ and tables in his presidential address before the Institution of Electrical Engineers on Jan. 10, 1889, for calculating the value of $\frac{R\,(N)}{R\,(S)}$ for a solid conductor of circular cross-section, where R (N) represents the ohmic resistance (not impedance) the conductor apparently has when traversed by an alternating current of frequency, N, and R (S) its true ohmic resistance. $\frac{R\,(N)}{R\,(S)}$ is therefore a coefficient depending on the size of conductor, etc., by which the resistance must be multiplied to obtain an *apparent* resistance which would account for the actual ohmic losses that occur when the conductor is traversed by an alternating current of given frequency.

By exactly the same procedure we can allow for the eddy-current loss in the sheath of the three-core cable; in fact, we can represent the total losses—viz., skin-effect and sheath loss numerically—by taking a definite increase of the resistance of the core per unit length for a given frequency. If ω_1 is the effective resistance of the core per unit length, and ω_2 its actual resistance per unit length

$$\omega_1 = \omega_2 \left(\nu + \frac{\xi}{3\,\omega_2} \right),$$

where

$$\nu = \frac{R\,(N)}{R\,(S)};$$

and

$$\xi = \frac{\cdot 72\, f^2\, \pi^3\, b_0^2}{10^{16}\, \rho_s} \left\{ \log \frac{\Delta_1}{\Delta_2} + \Sigma \frac{b_0^{2n-2}}{n^2\,(2n-2)} \left(\frac{1}{\Delta_2^{2n-2}} - \frac{1}{\Delta_1^{2n-2}} \right) \right\}$$

where n has the values 2, 4, 5, 7, 8, 10, etc., successively.

In calculating ν for a stranded core of circular section, the strands being laid on in concentric layers, we must insert for the specific resistance of the material the actual resistance of a centimetre cube of stranded core, measured between opposite transverse faces. This is generally about 33 per cent. greater than the specific resistance of the solid metal.

If we take the following figures as representing a typical three-phase cable with cores of circular section: radius of core = ·698cm.; distance between centres of cores = 2·03cm.; distance between centre of cable and centre of core = 1·18cm.; mean radius of sheath = 2·67cm.; thickness of sheath = ·477; current per core (effective) = 200 amperes; frequency = 60 cycles per second. We find

$$\nu = 1{\cdot}00 \quad \frac{\xi}{3\ \omega_2} = {\cdot}0236.$$

Thus the skin-effect is represented by an increase of the resistance of the core of less than 1 per cent., while the sheath loss by an increase of 2·36 per cent. If, now, we increase the linear dimensions of the cable cross-section $\sqrt{2}$ times, we have

$$\nu = 1{\cdot}035 \quad \frac{\xi}{3\ \omega_2} = {\cdot}0944.$$

We thus see incidentally that the sheath loss is a more important factor in large cables than the skin-effect.

HIGH-SPEED ELECTRIC RAILWAY EXPERIMENTS ON THE MARIENFELDE-ZOSSEN LINE.*

BY ALEXANDER SIEMENS, PAST-PRESIDENT.

On Sept. 4, 1901, Mr. O. Lasche, of Berlin, read a paper on a high-speed railway car before the engineering conference in Glasgow, which has been published in vol. 31 of the *Journal* of this Institution. Since that time three sets of experimental runs have been made with high-speed cars on the military railway between Marienfelde and Zossen, near Berlin, which had been equipped electrically for the purpose, and last autumn speeds of over 200 km. per hour were attained. Although further experiments are in contemplation, it may not be out of place to give a short history of the trials and of the preparation for them, as the main objects of the investigation have been accomplished. The English patent, 10926/86, "Improvements in the application of Volta inductors or secondary generators for distributing electrical energy and for regulating alternate-current motors, more particularly applicable to electric railways," communicated by Siemens and Halske, Berlin, forms a convenient starting point for such a narrative, as the Zossen experiments may be considered the latest link in the chain of development of the ideas enunciated in that patent. It is pointed out in the specification that "the use of Volta inductors or secondary generators for transmitting electrical energy offers the advantage of enabling a much higher tension to be employed than is possible with transmission by continuous currents, so that considerable energies can be transmitted through great distances by means of comparatively small conductors, while at the same time the regulation of the power of motion is capable of being effected much more easily." About the method of using the transformers in connection with electric railways, the specification suggests either to place them on the carriages or at certain distances apart along the line of rails. In the first case the primary coils are connected by rolling or sliding contacts to the conductor extending alongside the rails, which conveys alternate currents of high tension thereto; while in the second case the secondary coils of the transformers would supply low-tension currents to the working conductor, and thence to the motors on the carriages. As motors, dynamo machines that can produce continuous currents are recommended, and various methods of regulating them are described. The results obtained with such motors at that time were, however, not very encouraging, chiefly on account of the high frequency of the currents employed, and no important practical steps were taken until the three-phase motors began to occupy the attention of electrical engineers.

In March, 1892, Mr. Wilhelm von Siemens gave instructions to have a short experimental line constructed at the works of Siemens and Halske at Charlottenburg, and to try a 20-h.p. three-phase motor on it. The line was 360m. long, with a curve of 40m. radius, and 70m. long about the centre, the whole line being practically level. The current was supplied by a 50-h.p. three-phase machine, type R 32/26, and between two terminals of the same a difference of potential of 500 to 600 volts was kept constant. At the end of July the motorcar was finished, and it was successfully tried on Aug. 2, when loaded with 3,000 kil. At starting the motor was connected triangle fashion, and afterwards star fashion, running 1,400 revolutions per minute when the car was travelling at a speed of 22·5 km. per hour. The movement was transferred from the motor to the wheels by worm gear at the rate of 11 to 1. Encouraged by the results, Messrs. Siemens and Halske formally applied, on Oct. 29, 1892, to the Government for permission to equip from 40 km. to 50 km. of some Imperial railway near Berlin, in order to investigate experimentally the possibility of working the ordinary railways by means of electricity. They proposed to place transformers along the line, from which a low-pressure current would be supplied to the cars, and they explained their desire for such a long line by their intention to run the cars at a speed of from 60 km. to 70 km. per hour. On Nov. 12, 1892, the Government declared its readiness to take the proposal into serious consideration after the experimental line had been inspected by experts. Their visit took place on Dec. 2, but on Dec. 22 the application was declined, as the experts had not been satisfied with the method of collecting the current from the conductor along the line. In the experimental line two overhead wires were used, the rails forming the third conductor, and the Government experts, as well as some of the engineers of Messrs. Siemens and Halske, considered such a system as inapplicable to full-sized railways. The consequence of this attitude was another long pause in the development, until five years later, when Mr. Wilh. von Siemens initiated further experiments, in which, however, high-tension currents were to be supplied to the car. His view was that, at high speeds, the weight of the collectors had to be kept as low as possible, and that they would, for this reason, not be suitable to carry heavy currents; consequently the tension had to be kept as high as circumstances would permit in order to allow sufficient energy being transmitted to the car.

A waste piece of land near Gross Lichterfelde was placed at the disposal of Messrs. Siemens and Halske by the parish, and they built a short line, about 1,800m. long, of normal gauge, in 1898, equipping it with three overhead conductors for three-phase current of either 750 or 2,000 or 10,000 volts. At first the conductors were carried by insulators, each fastened to a movable wooden arm, and the current was collected by a horizontal bar, turning round a horizontal pivot, and pressed by a spring from above against the conductor. When the speed of running was increased, these horizontal bars jumped at the insulators and caused so much sparking that this arrangement had to be abandoned. In rebuilding the line the three conductors were placed vertically one above the other, at a distance of 1m., and the insulators to which they were attached were supported by an elastic cord stretched between the two ends of a channel iron bent in the form of an ellipse and fastened to the poles. The collectors were also modified, each consisting of a horizontal arm, turning round a vertical pivot, and carrying a vertical bow sliding along the conductor, a spring pressing the arm against the conductor. This arrangement was eventually found satisfactory for the highest speeds attained. While it was possible to settle by the experiments on this short line a suitable form of collector and a reliable construction of the overhead conductors, it became obvious that for trials at greater speeds the assistance of the railway department of the Government was indispensable. In the course of negotiations to obtain this, the scope of the proposed trials was widened in so far that the co-operation of other firms was secured by the formation of the "Studiengesellschaft fuer elektrische Schnellbahnen,"

* Paper read before the Institution of Electrical Engineers.

on Oct. 10, 1899. This syndicate consists of the Deutsche Bank, Delbruck Leo and Co, National Bank, Jacob S. H. Stern, A. Borsig, Phil. Holzmann, Friedrich Krupp, v. d. Zypen and Charlier, Allgemeine Elektrizitäts-Gesellschaft, and Siemens and Halske.

The War Office placed their single line between Zossen and Marienfelde at the disposal of the syndicate, and the President of the Imperial Railway Office became its chairman. Each year the syndicate has published a report of the trials of the preceding year, and all the data given in this paper are taken from these official reports, unless another source of information is specially mentioned. The permanent way of the military line consisted of rails weighing 33·4 kg. per metre, placed on iron and partly on wooden sleepers, and its condition was such that no greater speed than 80 km. per hour was allowed on it. In the first instance this was improved by relaying about 800 rails of 12m. each, increasing the number of sleepers by 4,000, and adding broken stone ballast to the extent of 4,000 cubic metres. This work was finished and the line, 23 km. long, ready for the trials on Sept. 3, 1901, when the official inspection was satisfactory. At the same time electric contacts, to be actuated by the wheels, were placed at 500m. distance from each other all along the line, and a registering apparatus at Mahlow station was connected to them, so that the speed of the cars could be verified there. The overhead conductors along the line were constructed by Siemens and Halske practically in the same way as the line at Gross Lichterfelde, with a device added to earth the line in case a conductor should break. At every insulator a metallic loop, about 30 cm. in diameter, extending horizontally towards the pole, is connected to the conductor, and a vertical copper wire passes through the centre of the loops, the copper wire being efficiently connected to the running rails and through them to the zero point of the three-phase generators, the rails being in addition connected to metal earth-plates at intervals of 1 km. Any interruption of a conductor brings it, therefore, at once into contact with earth, and prevents any accident by shock from the falling conductor. The efficiency of this arrangement was tested, both intentionally and by an accident, when the conductor fell on an official, but in both cases the earthing served as an absolute protection. The line is fitted at every kilometre with means of adjusting the strain, kept at about 1,000 kg., and with lightning dischargers of the horn pattern. At a distance of about 1 km. from Marienfelde (km. 8·5) the feeding line from the generating station Oberspree (13 km. distant), and built by the A.E.G., is joined to the line along the railway by a main switch.

Two carriages were built for the trials by v. d. Zypen and Charlier, constructed and fitted as corridor carriages in accordance with the rules of the German Railway Union. One of these cars, called "A," was furnished with its electrical outfit by the A.E.G., and has been described by Mr. Lasche as stated above, while the other was fitted out by Siemens and Halske, and has been described by Dr. Reichel (*E.T.Z.*, 1901, p. 671); in the reports the latter is called "S." Both cars carry the collectors, tested and approved of in the experiments of Siemens and Halske at Lichterfelde, with this modification, that in the "A" car each collector is carried by its own standard, while in the "S" car one standard carries all the three collectors. There are two groups of three collectors on each car. These cars were delivered on the experimental line in the beginning of September, 1901, and at first were drawn by locomotives so as to ascertain whether all their parts, especially the brakes and springs, were properly adjusted, and to study the mechanical behaviour of the collectors and conductors. Observations were also made as to the relative movements of the bogies and the carriages.

A final inspection was made on Oct. 1, and the permission to start running the cars by electricity was given on the following conditions: (1) The trials may be commenced at a speed of 100 km. per hour. This may afterwards be increased to 120 km., 140 km., and 150 km. per hour, and subsequently at increments of 10 km., provided that before increasing the speed an official inspection shows that the permanent way, the rolling-stock, and all other apparatus have given no trouble at the last speed. (2) Level crossings are to be closed all along the line before runs at more than 100 km. per hour are commenced, and proper catch-nets should be fitted under the conductors at the level crossings. (3) Experiments should at once be made to ascertain whether the electric instruments of the State railway and of the military railway are in any way affected by the working of the electric cars or by any breaking of the conductors. (4) The time-table for the runs is to be agreed with the direction of the State railway, running alongside the military railway, and the stationmasters from Marienfelde to Zossen are to be advised on what days trials at speeds of more than 100 km. per hour are to take place. (5) The conductors must not be charged with electricity, apart from the time-table, except at times sanctioned and announced to the railway authorities by the syndicate with a view of trials on the shunting rails.

At the trials the following rules and regulations had to be observed:

(*a*) *By Permanent-Way Officials.*—(1) The trials and electric tests take place only between 8 and 11.30 a.m. Except during this time the main switch at 8·5 km. must be open. It is to be kept under lock and key, which is in the custody of the representative of the syndicate. (2) Due notice of the time of the trials is to be given to all stations, Marienfelde to Zossen, and to all officials, including navvies, and no work is to be carried on during that time which might occasion contact with the conductors, nor is anybody allowed during that time to remain directly underneath the conductors or to lean against the posts. (3) As soon as the departure of a trial car has been announced by gong signal all gates at level crossings have to be closed, and the officials have to remain outside the gates until the trial car has passed. (4) If a conductor breaks during a trial nobody should touch the fallen ends until reliable advice has been received that the current has been cut off. Should the conductor break during the time the current is off, the ends should be placed out of the way of the ordinary traffic, and notice should be given to the inspector. (5) If any irregularity of the posts or of the conductors is noticed, the inspector should at once have this put right, or cause the syndicate to remedy the defect. (6) The permanent way between Marienfelde and Zossen is to be carefully inspected every day after the close of the trials, and any important irregularity is to be reported to the inspector, and no further trials must be run until the permanent way has been repaired. (7) To the stations, to the inspectors, and to the guards of level crossings, a copy of the pamphlet "First Aid for Accidents Caused by Electricity," is to be handed.

(*b*) *For Trial Runs.*—(8) When trials at a speed exceeding 100 km. are to be run, the representatives of the military railway and of the State railway at Marienfelde have to be informed the day before. (9) On the days of the trials the main switch at km. 8·5 may be closed after 8 a.m. The representative of the syndicate will permit the conductors to be charged when all work on the cars has been finished and all other preparations are complete. He then, with the consent of the engineer-in-charge of the respective electric company, will have the collectors brought into contact with the line, after a signal by a loud gong has been given in the shed. (10) As soon as the conductors are charged nobody is allowed on the roof of the cars, and after the collectors are in contact with the line no further work must be done on the cars in connection with their electric fittings or with their bogies. Offenders against this rule to be removed from the shed, and will not be readmitted. (11) Should it become necessary after the conductors have been charged to work at the bogies or at the electric apparatus of a car, the collectors are to be carefully removed from the conductors, and locked in that position in such a manner that no unauthorised person can move them. (12) Due care must be taken that the line and the level crossings are properly guarded before a run at a speed exceeding 100 km. per hour is commenced. (13) A commissary of the military railway, the representative and at least one other member of the syndicate, the engineer in charge and a fitter of the respective electric company, the driver on duty, and the car inspector should be present during each trial run. (14) The apparatus for starting and stopping the car must only be

Digitized by Google

handled by the engineer-in-charge or by the driver. (15) A portable telephone is to be carried, so that in case of accidents a communication with the adjacent stations can be established with the help of the two lowest wires of the military telegraphs. (16) Before the commencement of each run the representative of the syndicate and the engineer-in-charge will settle the speed and the brake trials of the run. (17) At each trial sand and water, for extinguishing fire, are to be carried, together with such tools as may be wanted for slight repairs. (18) When the run is interrupted owing to a defect observed on the car, the collectors have to be removed from the conductors before an investigation takes place. (19) During the run the driver should note any places where the car does not run smoothly, and should inform the representative accordingly. (20) Should a fuse melt at the generating station, Oberspree, it should at once be replaced, but if it blows again nothing further should be done until telephonic communication has been established. (21) After completing the trials for the day the car inspector should minutely inspect the car and remedy any defects. Particular attention should be paid to the state of the axles, the tyres, the bearings, the springs, and all parts of the pneumatic and hand brakes. A similar inspection of the electrical apparatus is to be carried out by the engineer-in-charge of the respective electric company, and the conductors along the line are to be examined by an engineer of Siemens and Halske. (22) In the car-shed a copy of the pamphlet "First Aid for Accidents Caused by Electricity" is to be exhibited, and all notices concerning the touching of apparatus, entering the cars, etc., are to be strictly followed.

On Oct. 3 and 4, 1901, the conductors along the line were officially inspected and tested under pressure, and on Oct. 7 the electric current was for the first time turned on to the cars. The Technical Committee of the syndicate had settled on Sept. 24 that the trials should be undertaken in such a manner as to ascertain (1) the highest safe speed on the line; (2) the proper construction of the permanent way; (3) the most advantageous construction of the car; (4) the most suitable electrical outfit; (5) the amount of energy at the various speeds; (6) the cost of working. To obtain the necessary data each car has been fitted with the following instruments: (1) a speed indicator for the driver; (2) a speed-registering apparatus; (3) an acceleration indicator; (4) a voltmeter; (5) an ammeter; (6) a wattmeter; (7) a phase indicator; (8) a pyrometer; (9) air-pressure indicators. The speed indicator registers the kilometres per hour, and is checked by the speed-registering apparatus on the car and by the instrument at Mahlow station, where the position of the car is indicated every 500m. by the wheel contacts along the line. Of the greatest importance are the observations in connection with the brakes, both as regards the time and the distance taken to bring the car to a standstill after it had attained certain speeds. At the generating station at Oberspree suitable instruments for registering volts and amperes were connected to the feeder, so as to check the apparatus on the cars.

Four sets of trials were to be run: (1) Starting and braking experiments up to a speed of 100 km. per hour. The generating station to supply current at 25 periods and the motors to receive current only long enough to attain the prescribed speed, when the current is to be cut off and the brakes are to be applied. (2) Running at an equal speed, with current of 25 periods, first from station to station and afterwards along the whole line, with resistances in circuit so as not to exceed the prescribed speed. (3) Similar experiments as under 1 and 2, but with currents of higher periods for speeds from 100 km. to 130 km. per hour. (4) Running with currents of 45 periods at speeds exceeding 130 km. per hour. The two cars were to be used on alternate days, and no increase in the speed was allowed unless everything had worked satisfactorily at the last speed.

On Oct. 8, 1901, the "S" car made its first run between the car-shed and km. 10·5, but while the current was on the signalling apparatus of the State railway and of the military line were sufficiently affected to require the construction of metallic returns along the whole line. This was finished in time for the regular runs of both cars to commence on Oct. 14, and they were continued until Nov. 30, with the exception of 12 days, during which the permanent way had to undergo extensive repairs. During these trials the cars ran about 3,000 km., of which 2,200 km. were under current, and for 800 km. the cars were pulled by locomotives before any current was used. The first two sets of experiments were carried out according to programme, and dealt with speeds up to 130 km. per hour, and they were principally utilised to ascertain the rate of acceleration and the data of braking. During the third set the speed was gradually increased until the "S" car reached a speed of 160 2 km. per hour on Nov. 5, while the railway officials made an inspection of the line in accordance with the regulations governing the trials. Even at a speed of 140 km. the running of the cars became irregular, owing to the condition of the permanent way, and at higher speeds the rails were bent, and their level was so much disturbed that the speed of the subsequent runs had to be restricted to 130 km. per hour. It was, however, possible to make valuable measurements of the energy required, and the working of the collectors and conductors could be observed with currents of 48 periods and 13,500 volts.

About the behaviour of the various component parts the report of the syndicate enters into great detail, of which a short summary only is given. At the generating station the steam dynamo and transformers worked quite satisfactorily, and supplied current of 25 to 50 periods and 6,000 to 14,000 volts. The feeder consists of four conductors, each of 50 square millimetres in section, the fourth conductor connecting the rails to the zero point of the two transformers. The conductors along the line, constructed, as described above, by Siemens and Halske, have given no trouble whatever even in heavy rain or hoar-frost. One of the most important problems—namely, to ascertain how large quantities of energy can be transferred from a standing conductor to a rapidly moving car—has been successfully solved by the construction of the conductors and of the collectors, both of which were the outcome of the experiment at Gross Lichterfelde. Both carriages, built by Van der Zypen and Charlier, ran in a very satisfactory manner, and ran steadier at a speed of 120 km. to 130 km. per hour than an ordinary corridor train carriage at 90 km. per hour. At higher speeds, the irregularities of the permanent way made the running dangerous. In the two articles mentioned above, the electrical arrangements of the two cars are described in detail.

The report of the syndicate makes the following observations: (*a*) It considers the switching arrangements of the "S" car more complicated than those of the "A" car, and suggests for both cars that it should be possible from either end to set both groups of collectors simultaneously. (*b*) The transformers in both cars are cooled by air, and have worked well during the trials. In car "S," after running 230 km. in succession, necessitating 14 accelerations to a speed of 120 km. per hour, the temperature of the transformers was only 25deg. C.; they were therefore considered sufficiently large to stand long runs, especially as they worked well with 12,000 to 13,000 volts. On the other car the transformers were much lighter, but they were never overheated, only on Nov. 19 a primary coil was short-circuited by a current of 12,000 volts. After that date currents of no more than 8,000 volts were permitted, so that the point could not be settled whether the transformers on this car could be used for long periods with high voltages. (*c*) Each of the motors on both cars is designed for 250 h.p., the "A" car motors taking current at 435 volts, and the "S" car motors 1,150 volts, while the pressure in the secondary circuit is 650 volts when standing still and during acceleration. No difference in running was experienced, although the motors on the "S" car are rigidly fixed to the axles of the wheels, while the motors on the "A" car are carried by the bogie frame and drive by an arrangement of springs. The report prefers the latter arrangement, and suggests trying a third method—driving the wheels by connecting rods. (*d*) The switches and resistances present another feature in which the electrical arrangements of the two cars differ; on the "A" car liquid resistances were employed, regulated by pumps, while metallic resistances were carried on the "S" car. Both arrangements gave no trouble during

Digitized by Google

these trials. The metallic resistance switches are more complicated than the others, but they work faster.

(To be continued.)

COMPARISON BETWEEN DIRECT-CURRENT AND POLYPHASE SYSTEMS FOR ELECTRIC WINDING PLANT.

BY JOHN G. HOOGHWINKEL, M.I.E.E.

In the first place, the choice of the type of motors to be used for driving winding plant depends on the type of winding engine to be used, and on the source of the electric power. The latter may be generated in a power

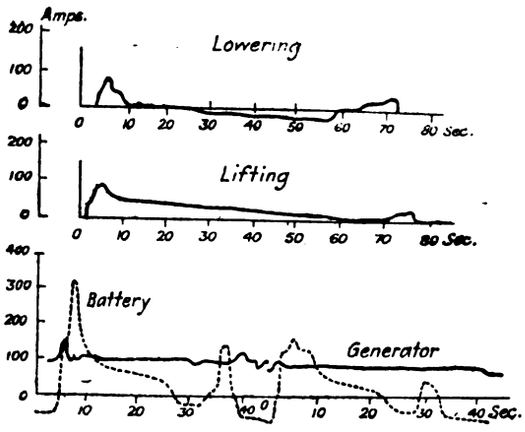

FIG 1.

station on the mine, only, or at least for the greater part, generating power for the winding machines; or it may be taken from the supply mains of a central power company, supplying several mines or a whole district. In the first case the power station will be near the pit's mouth, and probably generating continuous current. In the latter case the supply will be at a high voltage—say, 10,000 volts three-phase current with a periodicity of 40 to 50.

I. *Separate Power Station.*—Dealing with the first case—a separate power station for the winding plant (which is the most important part of a mine equipment and requires most of the total power used)—let us consider

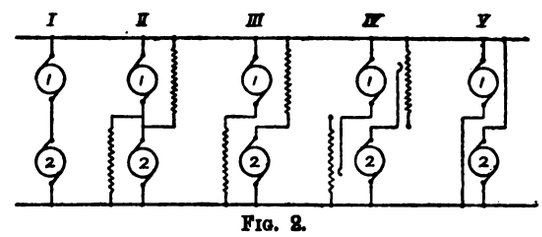

FIG. 2.

for speed regulation. (3) There are heavy losses, due to braking, as all the energy is wasted, while continuous-

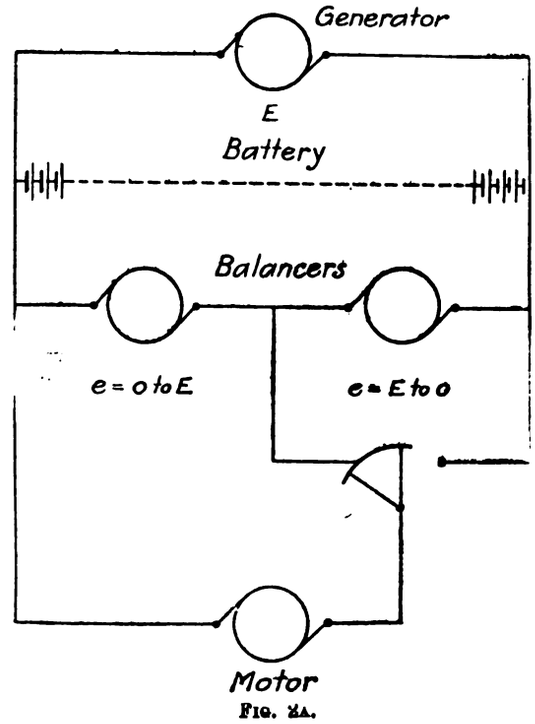

FIG. 2A.

current shunt motors constitute an efficient automatic brake while paying back energy to the system. (4) It is

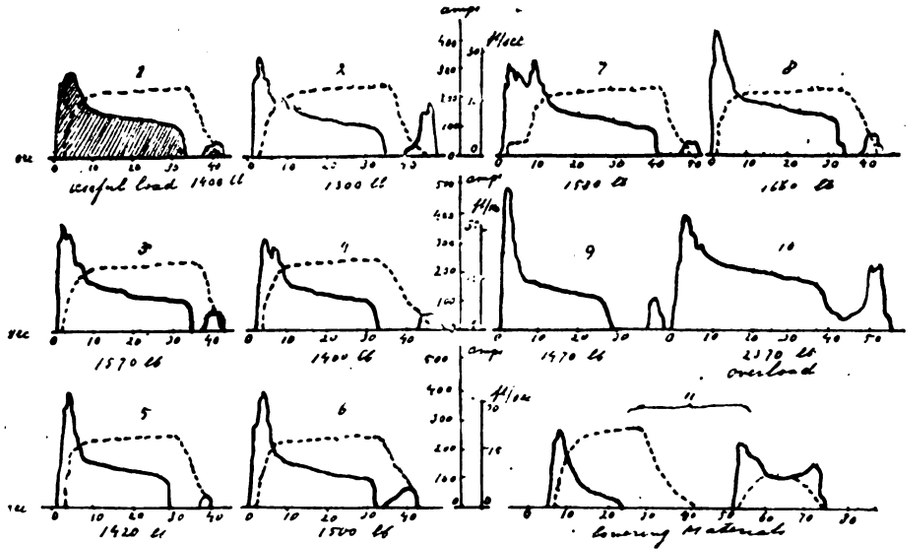

FIG. 1A.—Winding Diagrams of the Winding Plant at Tiederhall—Direct Current, with Battery, Double Drum; useful load, about 1,600lb.; non-balanced rope; speed, 22ft. per second; depth, 650ft. .... speed; — current.

first of all the efficiency and first cost of a direct-current and a polyphase equipment. If we are free in our choice of the system, the direct-current system is undoubtedly the best, owing to the following inherent qualities: (1) The polyphase motor cannot be started and regulated without considerable losses, which losses can be for the greater part avoided in direct-current plant. (2) The polyphase motor working at low speeds (40 to 60 revolutions per minute) requires a frequency of 25 or less, so that the station is not very well adapted for other purposes, such as not possible to make use of the highly equalising powers of a storage battery for equalising the load on the main engines. (5) The main engines have to be of greater capacity with three-phase plant, and the flywheels which may be used to produce the same effect as a battery are extremely heavy (up to 100 tons). The losses referred to in (1), which are by far the most important (up to 50 or 60 per cent. of the required total energy for each complete wind), can be for the greater part avoided with continuous-current motors by using one of the following

Digitized by Google

arrangements. The writer does not propose to describe each system, but simply to point out the advantages and drawbacks of each in particular.

By the battery method the equalising battery is divided into several, say five, parts, which provides a starting device without the usual rheostatic losses, in switching on the battery groups one by one, thus applying a gradually increasing voltage to the motor. The battery, of course, introduces losses in the battery, but these are very small. The writer would refer to the Tiederhall mine, where a winding plant on this system has been at work for three years. About one-third of the total energy passed through the battery, which has an efficiency of 85 per cent., being used as a battery in a traction station, *not* as a capacity battery, as in lighting stations. The most important advantage of the battery, however, is its equalising effect. The main steam-engines need only supply the *average* power, which is much lower than the amount of energy required to overcome the *static* forces. Fig. 1 shows the proportion between the maximum required energy and the average. The writer took the diagram from the Tiederhall mine after the installation had been running one year without a single hitch If no battery had been used, the main generators would have been calculated powerful enough to give the static torque. This saving in the output of the steam sets *largely* balances the cost of the battery, as a battery costs about half the price of a steam set (and boiler capacity) of the same output. As regards efficiency, it was found at the Tiederhall mine that for every horse-power useful load lifted at the shaft the required power at the steam-engine was 2 b.h.p. to 2·2 b.h.p. These figures have been checked by the writer in several other modern electric winding installations established on the same system. They compare with 3 b.h.p. to 3·25 b.h.p. in the three-phase installation at the Hohenegger mine, which is of about the same output. The annual saving in coal, therefore, fully pays for the maintenance cost of the battery, not to mention the other advantages—such as longer life for the steam sets, steady load, economical cut-off, etc. While lowering materials, etc., and during the braking period, energy is stored in the battery, and the writer considers this system the best for *heavy* electric winding plant supplied either by its own steam set or by a continuous-current main station.

It is not necessary to describe in detail the various arrangments which have been designed to gain the same advantages as the battery starting system, but they will be shortly enumerated. The disadvantage of using an equalising battery at the same time for starting, is a certain complication and the necessity of heavy switches. To obviate this, it is possible to use *for starting* (the use of a battery as equaliser is independent of this duty) in order to avoid the rheostatic losses: (1) a set of balancers to supply different voltages and to equalise the discharge of the battery, doing away in this case with the battery switches; (2) Leonard's system of separate excitation of the dynamo and the winding motor; (3) the starting motor-generator system.

Starting motor-generators can be arranged in different combinations. The best arrangements are II. and IV. (in Fig. 2), as the machines are only half the size of the winding motor. Although the first cost of these machines is rather high, their use secures some very valuable advantages—viz.: (*a*) Any position of the controlling lever of the winding machine corresponds to a fixed speed, which does not vary, even if the load becomes negative (when lowering materials, etc.). This is all-important, as it gives great security in handling the plant. (*b*) The starting losses are reduced to a minimum, and, therefore, the same saving in coal is obtained as with a battery. The losses are only confined to the no-load losses of the motor-generator, which are small. Also, it may be remarked, that any speed can be maintained without increasing the losses in the motor-generator. (*c*) The regulating switches and apparatus are small, being only inserted in the shunt circuits. (*d*) Anothe advantage is the brake action of these machines, as when pulling the lever back we brake the winding motor, and gradually stop at the same time, thereby putting energy back into the network. This system has been installed in various collieries—viz., Friederch Franz Mine, etc.

A combination of a starting motor-generator and the Leonard system of separate excitation, combined with the use of a high-speed flywheel on the motor-generator, has been introduced under the name of Ilger system (Fig. 3). This system can be used with any supply of *any* frequency, and is, therefore, in the writer's opinion the only system to be used with winding plant, taking its supply from a power company, which, having regard to its lighting load, will often work at a frequency of 50. It has been installed in the Zollern II. mine. Many installations (up to 17,000 h.p.) are in course of erection.

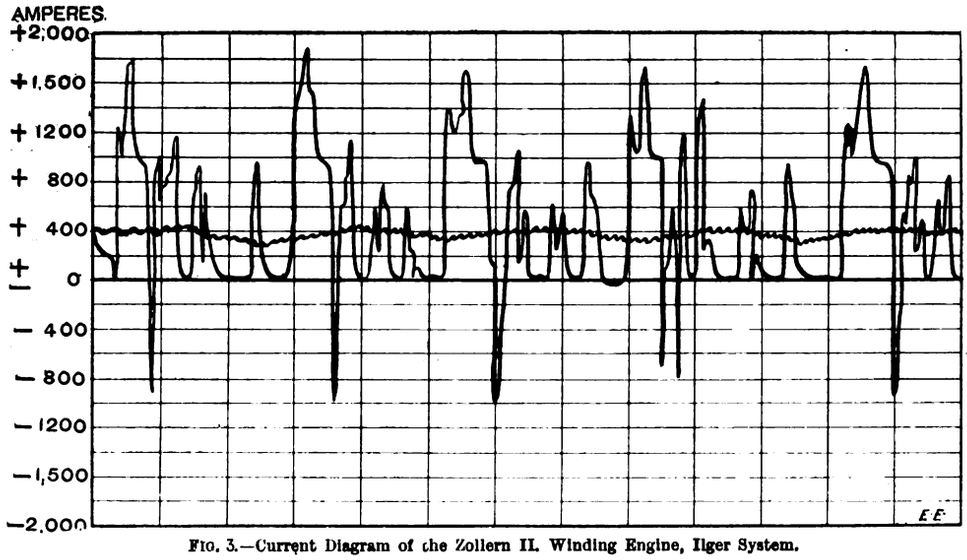

FIG. 3.—Current Diagram of the Zollern II. Winding Engine, Ilger System.

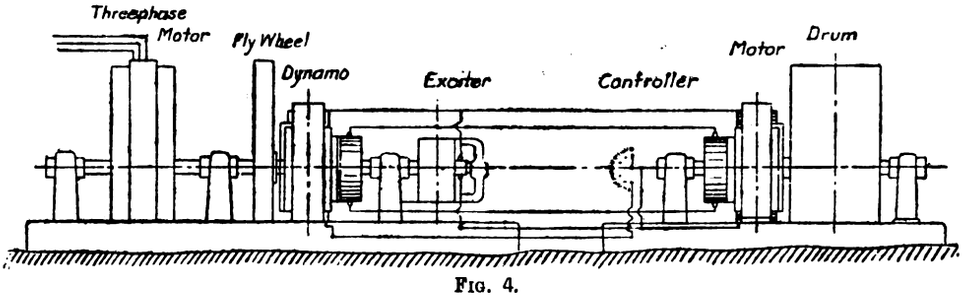

FIG. 4.

Digitized by Google

All these arrangements for starting aim at reducing the heavy starting losses to a minimum. With polyphase motors this is not possible. The only way is by using two motors in concatenation, but the difficulties due to the required heavy starting torques and to field leakage have not been successfully overcome for this kind of motor, although for railway motors it has been done (because of the less frequent and easier starting). Also the automatic electric brake action has not been successfully arranged for yet. The heavy losses due to the resistance in starting and regulating remain, and, as remarked before, often amount to 40 to 50 per cent. of the total energy. Also the steam sets have to be more powerful, as explained above, and, moreover, the steam consumption is greater than with a continuous plant with battery, as the engines run between 0 and maximum cut-off, or, even when a heavy flywheel is used, at least below the normal cut-off.

Recapitulating, we have, therefore, the following advantages for the continuous current, comparing a separate polyphase electric winding installation, where the winding load forms the greater part of the output, to a continuous-current installation with battery or on the Ilger system: (1) Capital outlay is practically the same, as cost of battery or other auxiliary plant is nearly balanced by high cost of more powerful main generators. (2) Steam and fuel consumption are about 30 per cent. less with continuous-current plant, due to the absence of starting and braking losses and equal load on the steam-engines, running at their most advantageous and constant cut-off. Also no losses due to the presence of a heavy flywheel. This estimate of 30 per cent. has been found to be correct in actual practice, as referred to before, but cannot very well be calculated, because of the varying steam consumption curves of engines of different class and output, and because of the varying starting losses. The writer is of opinion that it can be exceeded. (3) There is a greater security and easier and more perfect speed regulation, owing to definite and constant speed corresponding to each position of handle, also automatic braking without wear and tear on the other brakes and plant. (4) As regards the Ilger system, there is the possibility of using a frequency as high as 50 periods, giving greater facilities for lighting, etc. (5) Light and simple regulating gear is used. (6) There are no prohibitive load variations at the station having regard to lighting, etc. 7. Less copper is required in high-tension line to winding motor due to equally distributed load. In Fig. 3 can be seen the perfect equalising effect of the Ilger system on the last diagram taken at the Zollern II. mine.

II. *Power taken from a Large High-Tension Power Station supplying several Mines or Districts.*—In this case, of course, where the winding load is only a small part of the total load on the power station, or where even more than one winding machine is run from one station, most of the advantages of the continuous-current winding plant, though still to be considered, decrease or even disappear. The fluctuations of the load having less influence on the main engines, these are running on more even load, their steam regulation does not vary between 0 and maximum cut-off, and the steam consumption is much better. However, the starting losses remain, and these are 40 to 50 per cent. of the total energy, especially when the winding speed exceeds 12 yards per second. The writer is, therefore, of opinion that in most cases continuous-current plant with starting motor-generator and high speed flywheel has decided advantages which will soon pay back the extra cost of the slightly more expensive plant of the continuous-current system. For winding plant supplied from a main power station supplying several pits, three-phase motors should be adopted. For a large winding plant supplied by its own generating station, continuous-current with motor-generator or battery is superior to almost any other arangement.

ON INSULATION.

It may be taken for granted that testing the insulation of an electrical machine after completion, without any previous satisfactory knowledge of the insulating materials used in its manufacture, is far from being the correct thing to do. If, then, we are to choose between the various insulating materials on the market (each of which may be good for a particular purpose), it becomes essential to institute some preliminary tests. As to what should be the nature of these tests, it would be profitable to first consider what the insulation has to do, and under what conditions. These points will determine the nature of the tests it will be profitable to make.

It will be beneficial here to note some of the conditions which have to be fulfilled by a good insulator, though it may not be absolutely necessary that one particular insulator should meet every possible condition. These conditions may be broadly divided into two classes—viz., those necessary for convenient and cheap manufacture, and those essential to the longevity or commercial efficiency of the machine.

Taking first "paints or varnishes," we find the following features desirable, if not absolutely essential: (1) they should be quick drying, and yet should not lead to great waste owing to the drying up of the solvent; (2) they should have considerable elasticity and strength; (3) have a high melting point, and should not lose their insulating properties or char with possible rises of temperature in practical use; (4) should not chemically affect the copper conductors; (5) must be waterproof and unaffected by oils, acids, and, as sometimes specified, salt water; (6) last, but not least, should be good insulators.

Secondly, with regard to insulating fibres, papers, and tapes, we know that some depend on the nature of the material for their insulating properties, whilst in others this is merely a medium for carrying an insulating "varnish or paint," and it is on this that the strength of the insulator, as such, depends. This latter class, which also includes a certain variety of tapes, should, as far as the insulating medium is concerned, with which they are impregnated fulfil the conditions enumerated above for paints and varnishes. Regarding fibres and papers in their "natural" state—*i.e.*, not impregnated with an insulating medium—they might be approved of if they meet the following conditions: (1) they should be tough, yet pliable; (2) should not suffer excessively as insulators should they be creased; (3) they should, as far as it is possible to make them, be non-hygroscopic; (4) should be able to stand all temperatures experienced in practice without charring or reducing their insulating properties; (5) should have high insulation per mil of thickness, except where their mechanical strength is the principal consideration. It will be obvious from the varied nature of insulating materials, and also from the fact that no one material meets all conditions, that a choice has to be made of such as will best suit the varying conditions of service, both mechanically and electrically. With careful attention to this point considerable reduction in the cost of insulating materials may be effected in the manufacture of various electrical apparatus, though the cheapest insulation is not always the best.

Returning to the subject of varnishes and paints, let us look at the first of the properties required—viz, "quick drying." It will be obvious to anyone acquainted with shop methods the great saving in time and the increased output that can be obtained from a given drying stove, the more "quick drying" the insulating medium is. With this object in view resource has been made to shellac, copal and resin varnishes, using alcohol as a solvent. This would not be objectionable but for the fact that when the spirit (and also the water it carries) has been dried out, the resulting solid is too brittle. This solid under vibration or due to expansion and contraction, as the winding heats up and cools down, is in time reduced to a powder, and is then, of course, useless as an insulator. Should it be a revolving portion of a machine that is insulated with these varnishes, then centrifugal force will assist in the destruction of the insulation. Oil "varnishes" are not "quick drying" unless an objectionable amount of "dryer" is introduced. A considerable amount of waste occurs where the varnish has to be painted on coils such as are inconvenient to dip. Further, all tanks used in dipping coils should be provided with covers when not in use. Even whilst in use attention has to be paid to the consistency of the material owing to constant evaporation, and

Digitized by Google

"thinners" have to be added, as when used too thick more insulation is added than is required, leading to needless expense.

2. The second property claimed is that of elasticity and strength. From this point of view all mixtures, as distinct from chemical compounds, should be avoided. They are objectionable because of separation through settling. Should this be overcome by frequent stirring it is only temporary, as separation can take place after application. These mixtures are often brittle when thoroughly dry, and this considerably impairs their use. The American asphaltums, or, as as they are re-christened here, varnishes, are satisfactory at first as regards elasticity, but in time become brittle.

3. If high melting point is forthcoming, coils or armatures may be satisfactorily baked. Armatures, however, running at high peripheral speeds, especially turbine armatures, throw off the varnish in which they have been dipped at comparatively low temperatures, as the high centrifugal force assists in this work. This is, of course, a great disadvantage, covering as it does the field winding and poles with a discolouring varnish. It may be noted here what temperatures may be expected under working conditions. The writer knows of one or two electric lighting stations where the temperature is not infrequently about 100deg. F., and with the usual 70deg. F. rise of temperature stipulated in most specifications, we get 170deg. F. as the final temperature. This, it should be noted, is only at points convenient of reaching, and consequently internal parts of the windings will be considerably higher. It is certain, therefore, that insulating materials should not melt or have their insulating properties deteriorated under a temperature of at least 212deg. F. Even this will probably leave no margin. Insulating materials should be tested throughout the working limits of temperature, as some lose their previously high insulating properties when the temperature is raised to the working limit, whilst the insulation in some cases chars or carbonises. This is a very important point, as many engineers insist that pressure tests on plants must be made immediately after a lengthy full-load run, and sometimes an additional run of two hours on 20 or 30 per cent. overload. The machine will, of course, be still warm and most likely warmer than at any time on load, as the cooling effect of the revolving parts has then ceased.

4. Affecting the copper winding chemically applies more particularly to varnishes, but as insulating materials are generally secret mixtures, it is not safe to say that all paints are free from this fault. If, however, care is taken to neutralise any acids, such as would attack copper and gives us the green deposit of copper sulphate, this fault is done away with. The moisture in the cotton covering of wires, not dried out before varnishing, assists in this chemical action which destroys the cotton covering, and thus leads to short-circuiting of the turns. It would be as well to mention here that cotton covering is much to be preferred to paper, which is readily cut on the edges of flat strip copper. Cotton covering should never be single, and if to be roughly handled should be braided.

5. The material should be impervious to moisture, unaffected by oils, acids, and salt water. It is, of course, well known that water is an undesirable attendant of insulation, and, therefore, there is no need to labour this point beyond mentioning the specially adverse conditions to which some outside work is subjected, as, for instance, traction motors of all descriptions, motors for small tools in shipyards, etc. Insulation should certainly not wash off within a reasonable time. Regarding oils, many machines are subjected to trouble from this cause; motors from faulty bearings, etc., and generators from this cause and, where placed between engine standards, from splashing of oil from the engine. Acids are detrimental to insulation, and more than one machine has had to be rewound owing to being subjected to the acid fumes from battery-rooms. Salt water has been added by engineers in cases of exposed stations near the coast, especially where the voltage generated is high, though in the case of low voltage it would only be a question of time if the insulation was not impervious to salt water.

6. The material should be a good insulator. This goes without saying, and if this is not forthcoming, the properties previously enumerated are of no account whatever. A thickness of insulation of ·003in. thickness should stand at least 2,000 volts alternating R.M.S. value. It is well to notice that fibrous materials dipped in insulating compound rarely add their full breakdown strength to that of the varnish, and it is as well to look upon the material as only a medium of applying the insulating varnish.

Turning now to fibrous materials (including papers and tapes), it will be obvious that where the paper, tape, etc., is used merely as a medium for carrying the insulating varnish, that that insulator should remain intact, that it should not crack on handling the tapes, etc.; consequently those insulators having the property of elasticity are invaluable for this use.

Considering the fibres in what we have called their "natural" state, the first property mentioned was pliability. This is essential from a manufacturing standpoint. A pliable material is much easier to work with than a stiff one, and results in a considerable saving of time. It is frequently found more convenient to use several layers of thin material for ease in handling. It is here that a good insulator scores over a poorer one, as fewer layers are then necessary.

In handling many fibre and paper insulators, it is almost impossible to avoid creasing the sheet, these materials being usually supplied in sheets or rolls. This brings us to the second point regarding this class of material. This creasing, whether accidental or intentional, should not materially weaken the strength of the material as an insulator. Further, creasing "fibre, presspahn, etc.," destroys the glazed surface, and this makes the material more hygroscopic, and is thus likely to reduce its insulating value. This class of insulator is naturally hygroscopic, and it is almost entirely on the glazed surface that dependence is made to keep out moisture. Care should be taken to inspect fibrous materials other than woven fabrics, as it sometimes happens that pinholes and very thin places are to be found, and at times small particles of metal, such as filing dust, is rolled into the material. Both of these faults are undesirable, the latter especially so.

4. That insulating materials should stand all temperatures likely to be experienced without charring will need no demonstration, but many of this class get brittle when subjected to even "reasonably" high temperatures, and then lose whatever merit they had as to strength, especially mechanical strength. In case of a short-circuit on a machine, the increase of temperature in the portion of the machine supplying current to the short is frequently very great; but it is certainly undesirable that this should necessitate the rewinding of a considerable portion of the machine.

5. That insulators of any description should have a high insulation per mil of thickness is a very important matter, especially in generators and motors, when looked at from the "space factor" point of view. It is surprising what a large percentage of the available winding space is taken up by insulation in generators and motors, more especially in high-tension alternating-current work.

Having considered in detail the points of good insulation, it remains to consider what tests can be conveniently made with a view to securing as many good points in the insulation used, always bearing in mind that electrical tests are by far the most convenient in a manufacturing works, which is generally far from being a chemical laboratory. Particulars of tests as published by manufacturers of insulation are at times misleading, as frequently it is not stated whether the breakdown voltage was with continuous current or alternating current, and if the latter, whether the value is R.M.S. or maximum. Further, some manufacturers test between terminals shaped hemispherically and others between two flat discs. Again, some only test for an instant at the voltage named, merely bringing the voltage up and down again. It is possible, therefore, for the material to break down under a much lower voltage even if only sustained for a short time. Information of this description is of no use to the designer, that will readily be understood. Consequently some systematic way of testing all insulating materials is required. This need only be "thorough" on first testing a new material,

Digitized by Google

as there will be probably many evidences visible on mere inspection which would lead one to expect changes in the material. Subsequently a far less pretentious test will be all that is required to ensure repeat orders of material being satisfactory. As the best means for obtaining high pressures, and also of varying the pressure, is by means of alternating current, this, of course, should be used. It must be noted that varying periodicity would give varying results; also that the shape of E.M.F. curve affects the results in the same way, a peaky curve being more apt to break down the insulation than a flat curve, though both may have the same R.M.S. value. An alternator giving 50 periods and approximately a sine curve of E.M.F. would be suitable and would correspond somewhat to prevailing practice in alternating-current work in England. A variable-ratio transformer is practically indispensable for obtaining the varied voltages required to test the different classes of insulators. Though it may be possible at times to use one of two machines for testing purposes, it is preferable to stick to one (unless the machines are identical), as the more constant the conditions of testing the more reliable is the information obtained. The larger the works and the more elaborate might be the testing, but however simple the apparatus, it is desirable to pressure test all insulating papers, etc., at varying temperatures on first testing unknown materials, afterwards it would probably only be necessary to test at one temperature, supervision being kept over the appearance of all materials, as variations from the standard article are thus detected. Supervision is most essential in connection with varnishes and paints, and attention to appearance should, if possible, be supplemented by testing with the hydrometer to see that the specific gravity does not change. This is partly a check on its chemical constituents, any alteration in chemical composition generally affecting its specific gravity.

Taking tests for the specific points, mentioned for insulating materials in the foregoing, in the order named, we have for paints and varnishes:

1. *Quick Drying.*—This is merely a matter for trial, and can be done either in the open air or in a drying stove, as desired.

2. *Elastic Strength.*—This may be tested by coating a piece of pressphn, tin or copper (metal for preference), and when dry bending backwards and forwards. An electrical test can also be made after the bending, to see if this has affected the insulating material.

3. *High Melting Point.*—First dry off the liquid components and then heat the residue, and see at what temperature it melts. If the drying was done in a thin layer, it would also be possible to note when it commenced to char.

4. *Affecting Copper.*—Copper strips may be coated and examined after an interval (which is practically working conditions), but a quicker way is to put copper filings into a quantity of the varnish. They will readily show if the varnish will in any way affect the copper.

5. *Waterproof, etc.*—The varnish or paint could be tested on some plant about the works, where there is generally some motor or other running under adverse circumstances as regards oil, etc. A test might be made of a piece of metal left exposed to the elements for some considerable time.

6 This we will deal with later, along with 4 and 5 for fibres, etc.

Taking now fibres, papers, etc., we find

1. *Pliability.*—This is, of course, purely a matter of trial.

2. *Creasing.*—A good test to subject the material to is to make two creases crossing each other. This is likely to be as severe as anything short of an actual tear.

3. *Non-Hygroscopic.*—This might be tested by immersing all samples systematically for a short time in water and then testing for breakdown after drying the surface.

The tests for 4 and 5 for fibres, papers, etc., and for 6 in varnishes and paints, can conveniently be made in a felt-lined box, heated by either lamps or a resistance frame, the latter for preference if the higher temperatures are desired. If a thermometer be fixed projecting into the box, the desired temperature is easily noted, and can be regulated by varying the current through the resistance. The box should be fitted with two terminals about 1½in. in diameter, the flat surfaces having the sharp edge rounded off to prevent excess of pressure at these points. If one of the terminals be fitted with a flat spring, a fairly uniform pressure will be secured, as the thickness of the samples tested does not vary within very wide limits. Ordinary instruments would be necessary for reading current and voltage, the ammeter indicating at once the breakdown of any specimen under test. It is the systematic recording and making of these electrical tests that enable the designer to make the most of the materials at his disposal. They also, as previously noted, keep the materials used up to sample, and therefore more reliance can be placed on the work of the various departments. One point remains to be emphasised in pressure testing, and that is that the breakdown strength is not proportional to thickness, especially in the case of fibres and such like materials which are built up in layers. It would appear very difficult to get rid of moisture in the thicker sheets, and this brings down the insulating strength.

A very important test which should not be overlooked is the galvanometer test for leakage, as some materials may be good against piercing and yet be bad from a leakage point of view. Take mica-paper for instance. This, if the mica is well laid—that is, with all joints well lapped—will show well under a disruptive test, but for leakage would depend entirely on the mucilage or varnish with which the mica flakes are built up. Failing a standard galvanometer testing set, a rough test may be made by testing against a known good insulator, and noting the discharge and the length of surface over which it takes place. This can, of course, only be done when the thickness of the piece tested is secure against breakdown from the pressure applied to obtain this discharge. Every care should, of course, be taken to accurately gauge the thickness of material under test, especially at the point of breakdown.

In conclusion, it may be said that attention to this question of insulation is amply repaid, and it is well to bear in mind that it is not well "to spoil the ship for a ha'porth of tar."

GERMAN COMPETITION.

BY SIMPLEX.

Out of respect to our German competitors the following verses are written in English as they understand it.

Dere vos a man from Yarmanie
Mit glow lamps dat vos made to sell.
His voice was voll of 'armonie
Und he could blow his trompet well.

He vos not moch at which to look.
His manners were der greasy sort.
But he could yaw like any book,
For he der English tongue vos taught.

He vos a piggish little man.
His moral code vos a surprise.
He fed himself upon a plan
Of diet dat you would despise.

But ach! Der sheapness fon dose lamps!
Die (verbal) guarantees he gave
Of candle-powers compared mit amps.
Und cost of energy we'd save!

Ach me! sechs tousand lamps we bought!
Dey looked so nice und goot und new—
Der first one caused a total short.
Die rest—we give dem *all* to you!

Dey haf *no* life to talk about;
Und if you schwear at dem, dey break!
Die globes are always coming out;
Die plaster crumbles at a shake.

We do not lofe das Doitcher Mann!
But he is now a Companie,
Und advertises all he can
"Support a British industry!"

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notices of Meetings, Issues of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had by Order from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	— 6s. 6d.	— 13s. 0d.
Other Places	5s. 6d.	— 10s. 6d.	— 21s. 0d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

THE WOOD GREEN CASE.

There was recently held at Wood Green a Local Government Board enquiry to consider an application from the District Council for a loan of about £43,000 for electric lighting purposes. There was considerable opposition to the application from the North Metropolitan Electric Power Distribution Company, who wished to obtain a contract to supply electricity in bulk to the Council. In consequence of this the enquiry lasted over two days, and a large amount of figures were given on each side as to the relative financial advantages of the rival proposals. The engineers for the Council, Messrs. Hawtayne and Zeden, have been able to convince their clients that even during the first seven years it would be quite as cheap for the Council to generate current as to buy in bulk at 2½d. per unit from the company, but apparently they have not convinced the inspector. The Local Government Board's decision as to the loan has just been received, and it opens up various questions. It reads as follows: "I am directed by the Local Government Board to state that they have had under consideration the report made by their inspector, Mr. Hooper, after the enquiry held by him with reference to the application of the Urban District Council of Wood Green for sanction to borrow £43,200, since increased to £43,570. The Board have very carefully considered all information placed before them by the District Council, and it appears to them upon that information to be extremely doubtful whether the scheme, if carried out, would be likely to prove a financial success. The evidence given as to the probable demand for current was of an unsatisfactory character, for it was first stated that the demand was estimated to be equivalent to 330 consumers at sixty 8-c.p. lamps per house, but when it was pointed out and admitted by the engineer that the number of lamps estimated for was far too high considering the class of property to be supplied, the estimate of the demand was altered to 660 consumers at thirty 8-c.p. lamps per house. It does not clearly appear in what manner either estimate has been arrived at. The Board consider that the District Council before undertaking a scheme of the magnitude proposed should obtain more reliable information as to the extent to which the electric light is likely to be taken up. Moreover, the Board are by no means convinced by the evidence submitted to them that the District Council are acting prudently and in the best interests of their district in proposing to erect a generating station for the supply of electricity, and they think that the whole question, including the methods of supply, should be reconsidered by the District Council." The report is signed by Noel T. Kershaw, assistant secretary. There is no doubt that the consulting engineers were incorrect in their estimate of the number of consumers amongst whom the twenty thousand lamps estimated for would be distributed. It is equally certain that the estimate of twenty thousand 8-c.p. lamps is an exceedingly moderate one for the district in question, which has a population of close upon forty thousand. The alteration in the number of consumers required before these lamp connections have been obtained means an increase in the first cost for house connections. It does not invalidate in any way, however, the accuracy of the estimates for revenue and expenditure, and only slightly increases the capital charges. We are exceedingly surprised to see the Local Government Board asking for more reliable information as to the extent to which electric light is likely to be taken up. The Board of Trade returns are surely at the disposal of all Government departments, and the probable lamp connections from a given class of population can be quite accurately estimated from these, as can also the revenue. The letter reads as

Digitized by Google

though a canvass throughout the district as to who would and who would not become consumers were desired. If such is the case, we should have expected the inspector, Mr. Hooper, to correct the erroneous opinion of the Board, that such a canvass is of any service whatsoever. It is an Englishman's prerogative, and a freely exercised one, to refuse to state in writing what he will or will not do a year hence. Experience has shown in this country that a canvass is absolutely useless in ascertaining the probable support of a new undertaking. It is as futile as an attempt to sell goods which are yet to be manufactured and the character and fashion of which are unknown. It seems to us that the Local Government Board have on account of a quibble as to the number of consumers refused a loan which is required by the Wood Green Council to carry out its statutory powers There is, of course, the broader reason that the inspector may consider it more advisable for the Council to take a supply in bulk. This, however, raises a moot point as to the powers of the Local Government Board. The Wood Green Council has been authorised by a provisional order, confirmed by Act of Parliament, to supply electricity and to erect a generating station. It has agreed by a large majority of the elected representatives of the ratepayers to do so, and to make the station part of a scheme including a refuse destructor and baths. The sections of this scheme are to mutually assist each other. Thus the electric light department is to take steam from the refuse destructor, and help to pay the capital charges on the same. Has, then, the Local Government Board the power to compel the Council to throw away these advantages and to take supply from a private company? We, if we were councillors, should renew the application after reconsideration and reapproval of the present scheme, and ask that the inspector appointed be supplied with some Board of Trade returns from electric light undertakings in similar London areas.

A SPORTING OFFER.

The report of Mr. Hammond presented to the Dublin Council is something exceptional in character, and deserves more than casual attention. Without entering into the history of the Dublin installation, it is enough to say that Mr. Hammond is the consulting engineer. During the past twelve months he has also been the responsible manager, and under his management chaos has become order. An immense amount of organising work has been done, and according to the report the outlook is decidedly good. Fortunately or unfortunately, according to the temperament or politics of the individual, a good deal of rough, if not virulent criticism has been launched against the Dublin work and the consulting engineer. It is evident that he is quite sanguine as to the results in the future, and we should say, much to the dismay of the critics, has offered to prove his convictions in the most conclusive manner. This will be gathered from the alternative offers he has submitted to the Council. The criticism on this offer is, "If it would pay Mr. Hammond or his syndicate to work the undertaking from London, surely it will pay the Corporation of Dublin." All other things being equal, that is the natural and legitimate conclusion, but in this case we fear that it is a little difficult to give adhesion to the conclusion. Efficient administration under an autocrat is one thing, under the Dublin Council is another. Nepotism is the unknown factor which may play an important part in the future, unless the Council strictly adhere to employment of merit and ignore influence without merit. Fancy a consulting engineer of high repute having to explain the nationality of the members of the staff he employs. His aim is efficiency and economy, and from all points of view he would prefer the home-made article if it gave him what he wanted. We shall watch the future history of Dublin with interest.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

SECTION G OF THE BRITISH ASSOCIATION.

SIR,—The remarks in your issue of the 25th ult. on this year's work of Section G of the British Association at Cambridge have only lately been seen by me. In the past, no one more than I have has felt the deficiencies of arrangement and want of interesting matter in our proceedings, so I feel myself justified in asking your readers to realise the improvement which has lately taken place not only in the subject matter, but also in its arrangement. A few years ago, in these respects G section was worthy of all your severest strictures. I do not remember if it formerly escaped your notice or not.

As a member of the committee which assisted the president and the recorder, I may point out that the faults of arrangement, such as they were, were due, not to want of foresight, but to the traditional practice of the section in accepting papers up to and during the meeting itself. The meetings, as you are aware, are much less formal than, *e.g*, those of engineering societies, and it has always been the custom to accept papers when there is a fair chance of finding time for them, rather than decline them in fear of there being insufficient time to read and discuss them. If you will refer to the provisional programme published in your own columns before the meeting, you will notice that a considerable number of papers, including the whole of Wednesday's programme, were accepted after the meeting began. This was in accordance with the practice I have described, and you will perceive at once the difficulty of introducing a number of fresh papers into an already carefully constructed programme without the appearance of confusion.

The elaborate papers by Mr. Campbell Swinton and Mr. C. H. Merz, which occupied so much of Monday morning, had been promised, and had been set down for that day, as long ago as last January. This, as well as their own character, you will admit, justified the hearing they received. As to whether other papers, through pressure of time, received less, we shall not differ.

The committee of the section were anxious that papers contributed to the proceedings should not be lost, as has been too often the case, and this year for the first time it was suggested to all authors of papers accepted before the meeting that they should endeavour to arrange for the publication of their papers by the technical Press. A very large proportion of the papers of this year's programme have been already published *in extenso*, which you will admit is a valuable result. You have yourself published several.

The section has shared in the general growth and development of the association. It may be that, with growth, some modification of habit is required, but I think you have overstated the case.—Yours, etc.,

C. E. WEBBER.

[We are pleased to publish the above letter from Major-General Webber, and can assure him that our strictures on the management of Section G at Cambridge were prompted by a desire to improve the usefulness of the same. Our view is that when papers can be distributed in proof form to the meeting, as six out of the seven down in the Monday's programme were, it is a waste of time to read them in full. The discussion on Mr. Campbell Swinton's valuable paper was perhaps the most interesting that day, and it would have been equally possible if the paper had been distributed and then read in abstract. The same applies to the paper by Messrs. C. H. Merz and W. McLellan, which was very similar to one read by the same authors before the Institution of Electrical Engineers this year. With seven papers on the programme to get through and discuss in three hours, it does not require expert engineering know-

Digitized by Google

ledge to allot to each its due proportion of the time available. Thus, if Major-General Webber will turn to the programme of Section H for the same day, he will find the following: "Monday, Aug. 22.—10.15 a.m. punctually: (1) Sir Richard Temple, Bart., C.I E, 'A Plan for a Uniform Scientific Record of the Languages of Savages' (30 minutes); (2) A. W. Howitt, 'The Practice of Group-Marriage in Australian Tribes' (20 minutes); (3) R. S. Lepper, 'The Break-up of the Matriarchate' (20 minutes); (4) Edmond Demolins (Paris), 'Classification Sociale,' (20 minutes); (5) Prof. W. Ridgeway, 'An Anthropological View of the Origin of Tragedy' (30 minutes)." Thus some two hours were devoted to papers, leaving 45 minutes for the five discussions. Surely the committee and recorder of Section G, as engineers, are as capable of organising a three hours' meeting as the anthropologists.—ED., *E. E.*]

TELEPHONY AT GLASGOW.

SIR,—I must take issue with your statement of this controversy on p. 309 of the *Electrical Engineer*. My credibility is not in question at all. I have merely quoted various references by Mr. Bennett to the 1897 Glasgow estimate which directly conflict with Mr. Bennett's recent statement, quoted in your issue of Aug. 12, to the effect that the estimate was prepared for the special purpose of showing what the then existing system ought to have cost the National Telephone Company. As Mr. Bennett has made two conflicting sets of statements regarding this estimate, and all I have done has been to quote some of them, the only person whose credibility can be in question is Mr. Bennett. It is not a case of Bennett *v.* Webb; it is Bennett *v.* Bennett. As there are two directly conflicting sets of statements by the same author, the world must judge whether the weight of the evidence supports Jekyll or whether it supports Hyde.

The estimate is now said to have been made for the special purpose of showing what the then (1897) existing system in Glasgow ought to have cost the National Telephone Company. Let us see what is the evidence for and against this statement:

Pro.—1. That Mr. Bennett said so on cross-examination at Glasgow in 1897.

2. That Mr. Salvesen said so in his closing speech.

3. That Mr. Bennett said so at Hull in 1903. After a brief triangular squabble between the inspector, Mr. Robb, and Mr. Bennett, the inspector declined to hear the matter out, and gave no opinion on the point at issue.

4. That Mr. Bennett says so now.

Contra.—1. The then existing system was a single-wire overhead system. The estimate describes a metallic-circuit underground system. (*Vide* Glasgow Blue-book.)

2. The estimate specified a greater length of wire, a larger number of junction lines, and a larger number of exchanges than the existing system contained. (*Vide* Glasgow Blue-book.)

3. Mr. Bennett stated in 1896 (*vide* "The Telephone Question," by A. R. Bennett, published by Biggs and Co.) that Glasgow could be telephoned in modern style for £17 a line.

4. The Glasgow Corporation applied for a telephone license for the whole area in September, 1897. (*Vide* Glasgow Blue-book.)

5. The Glasgow Corporation sent out circulars previous to the enquiry inviting applications from prospective subscribers to the proposed municipal system. The circular said that the Corporation were advised by an experienced telephone engineer. (*Idem.*)

6. Members of the Telephone Committee of the Glasgow Corporation, in sworn evidence, said that they contemplated establishing a system to serve the whole area; that they had detailed estimates which would be explained by the engineer (Mr. Bennett's evidence followed that of the town councillors); and that they contemplated spending £100,000 or £120,000. (*Idem.*)

7. Mr. Bennett put in an estimate entitled "Estimate for Glasgow Municipal Exchange." (*Idem.*)

8. Mr. Bennett described the estimate in detail, showed and described a map illustrating the situation of the exchanges and the proposed cable and distribution system. He spoke of the system in the future tense, said that it "will do" and "will be" this, that, and the other, and that it "will give" a superior service to the existing service. He showed that it contained more line plant, more exchanges, and more junction lines than the existing system, and he drew many distinctions between the proposed system, as specified by the estimate, and the existing system. (*Idem.*)

9. Two independent expert witnesses supported Mr. Bennett's estimate. (*Idem.*)

10. Mr. Sinclair and Mr. Webb were both examined on the estimate on the basis of it being a working estimate for a proposed municipal system. (*Idem*)

11. The question of the cost of the existing system was ruled out by the commissioner, and was not discussed at all. (*Idem*, p. 61.)

12. The commissioner, in his report, refers to the estimate as having been for a Glasgow municipal system, and makes no reference to it being for any other purpose. (Report on Glasgow Enquiry, p. 17.)

13. Mr. Bennett told the 1898 Select Committee that the 1897 Glasgow estimate was quite correct, and that it was a statement of the ascertained cost of a Glasgow municipal system. There was nothing, he said to modify his Glasgow evidence, and he stood on the estimate with perfect confidence of its correctness. (1898 Blue-book.)

14. Mr. Bennett wrote to a Dublin paper, saying that Sheriff Jameson had not questioned the accuracy of his Glasgow estimate, that the 1898 committee had accepted it as correct, and that it was in effect correct and as applicable to Dublin as to Glasgow. (*Freeman's Journal*, September, 1899)

15. Mr. Bennett, in his report of February, 1900, to the Glasgow Telephone Committee, when work on building the system was about to begin, said that the 1897 estimate remained substantially correct, and appended a complete copy of it as the estimate to be worked to. He recommended that an additional £20,000 be spent on spare plant in and near the exchanges, but gave no detailed estimate or specification of this extra work. (Report by Mr. A. R. Bennett to Glasgow Telephone Committee, February, 1900.)

16. All statements put out by Mr. Bennett or by the Glasgow Telephone Committee relating to average capital cost compare the present calculated cost with the original estimate, or, to be strictly accurate, with the slight departure from the original estimate made in Mr. Bennett's covering report of February, 1900, in which he rounded out the £97,833 of the detailed estimate to an even £100,000. (*Vide* "Noteworthy Points," Glasgow Corporation Telephone Accounts, 1904, Report by A. R. Bennett.)

Now, Sir, as you say, the public, your readers, must judge on which side the weight of evidence lies. In this Jekyll and Hyde estimate you back Hyde, and I simply point out that Jekyll has talked much more emphatically than Hyde, and more often. Whether the public decide for Jekyll or for Hyde, they knock at the same door.

I have derived no little amusement from this controversy, and more, perhaps, from a feature which has not been touched on at all than from those which have been pulled and pounded out of shape by your other contributors. It has amused me immensely to observe that writers on the staff of a technical journal have failed to see the absurdity of arguing that an estimate for one thing could seriously be put forward to show what something entirely different ought to have cost. What engineer in his senses, instructed to appraise an existing system, would prepare an estimate for a system radically different in style of construction and quantity of materials? I may have an unflattering opinion of Mr. Bennett's attainments as a telephone engineer, but I give him credit for more common-sense than to imagine that if he were instructed to inform his employers as closely as he could what an existing system ought to have cost, he would retire to his office and elaborate an estimate for something totally different in all the essential points of design, construction, equipment, distribution, and general arrangement.

It must be clear to the most casual reader that if the 1897 estimate was intended to show what the then existing

Digitized by Google

system ought to have cost, it was not worth the price of a match to burn it.

I purpose now to leave this aspect of the subject in the hands of your readers. I have summed up the evidence, and I am content to let them give the verdict. For the next few weeks I hope to be where the *Electrical Engineer* is never seen and the fame of Glasgow telephones has not penetrated. When I return I may have something to say on some other points in connection with the Glasgow system not without interest to those concerned in telephony.—Yours, etc., HERBERT LAWS WEBB.

35, Old Queen-street, Westminster, S.W.,
Sept. 5, 1904.

SIR,—Mr. Webb has now restricted this controversy to a question of the consistency of Mr. Bennett. I do not intend to expand this question. I always think it is fairly easy to read inconsistencies where none are intended, but I exercise no stretch of the imagination in reading Mr. Bennett's utterances and actions as perfectly consistent throughout. It was on Oct. 2, 1897, that Mr. Bennett was examined. It was on Oct. 4, 1897, that Mr. Bennett explained, in his answer to question 5,359, what he meant regarding this much-debated estimate. Thus it is perfectly clear that if Mr. Bennett says now what he said then, his statements cannot be termed inconsistent. As I read it, Mr. Bennett does say now what he has said all along and what he said then. Let me once more quote Mr. Bennett's reply to the said question: "I think I made it clear in my evidence in chief that the estimate which I have prepared was designedly founded on a similar number of subscribers as exists at present in Glasgow, *for the specific purpose of ascertaining the approximate cost of such a system as exists here.* (The italics are mine.) That was the object, and it was never proposed that in the event of the scheme being given effect to the lines should be laid for such a small number of subscribers as 5,000 or 6,000."

From this it will be seen that the estimate was then said as is now said to be: "For the specific purpose of ascertaining the approximate cost of such a system as exists here." What other interpretation can anyone put upon these words of Mr. Bennett than the one I have put? I do not mind telling Mr. Webb that if I read Mr. Bennett's evidence as given on p. 103 of the telephone enquiry minutes, and also on other pages, *without* his explanation on p. 113, and especially his answers 5,359 and 5,360, I should perhaps be inclined towards Mr. Webb's view to admit some inconsistency, and possibly an attempt in some of Mr. Bennett's subsequent remarks to read something into his evidence. But I cannot see how Mr. Webb or anyone else can get over the explanation given in these replies, which are proof positive, without the slightest shadow of evasiveness, of what Mr. Bennett's evidence was intended to mean at the time it was given, and make quite clear the answers 5,041, 5,042, 5,043, 5,044, 5,045, 5,046, 5,047, etc.

It is perfectly evident from the answers at the enquiry that Mr. Bennett never intended to put forward this estimate as an estimate for a scheme he would suggest, and that it had not, and has not, the remotest connection with the scheme he carried out; hence the oft-repeated comparisons "cost of work" with cost as shown by this estimate are wholly misleading. After this controversy, and a further careful reading of the evidence if the comparisons are persisted in, I shall say, and say much more emphatically than will be good for the repute of those who persist in the comparison, that the comparison is not from ignorance of the truth, not from misinterpretation, but from a wilful desire to foist a lying tale upon an ignorant public.

I am sorry, Sir, that I find it necessary, in scotching this mistake, to consider shortly the "contra" items of Mr. Webb's letter.

1. Mr. Bennett never said, never suggested his estimate was for an *identical* system to the "then existing system." He took an equivalent in instruments, but connected them up in a better way, giving a benefit to the cost of the existing system. As I read it, his evidence was to the effect: "Here is what you have now got in Glasgow. I can give you the same result—aye, a better result—for £97,833. 3s. 8d. My estimate to obtain this result is practical, and here are reputable firms to carry it out if asked to do so, so that there cannot be much mistake in the figures. It will work, work well, better than the existing system, that I maintain." What was this evidence for? I don't know, but I can give a pretty shrewd guess. Not "identical," please, Mr. Webb, but "equivalent." Thus Contra No. 1 goes.

2. Contra No. 2 goes as No. 1. Mr. Bennett's evidence is to the effect, not only equivalent, but better; hence more of the things mentioned.

3. In the paper quoted Mr. Bennett was discussing Continental experience, and upon that founded an argument as to what the cost should be at such places as Glasgow, Liverpool, and Manchester. Nothing to do with estimate 1897. So Contra 3 goes.

Contras 4 and 5. Nothing to do with the matter.

Contra 6, again to effect: Yes, if we want an equivalent, there is the estimate and the cost. Mr. Jameson's report explains this, and proves that my contention is the true one. I have quoted his remarks (p. 308, Aug. 26).

Contras 7, 8, 9, 10, 11, 12, and 13 are merely incidental to an examination on the practicality of the equivalent estimate. How on earth could an examination take place, except to assume that the estimate might be put to practical use? Sinclair and Webb would argue the scheme must be a failure. Bennett and his side would maintain the contrary. All these go because Bennett merely said, "Here's a workable scheme for an equivalent, or something better, if that's all you want; but it is *not* my scheme."

Contra 14. The accuracy has not been questioned yet, only its accuracy when applied to something else.

Contra 15. Bennett has explained again and again that while he holds to the accuracy of his estimate at the enquiry, when Glasgow really made a start it wanted something different. I cannot give the date when Glasgow decided to have a completed and far different scheme to the mere equivalent, probably after the report mentioned.

Contra 16. Very probably. Mr. Bennett has his fads, one of which is around £20. He may be right, or he may be wrong, but that has nothing to do with what the estimate at the enquiry was intended to be.

Thank goodness, Mr. Webb's amusement is nothing to that he causes in telephonic circles. He fails to see that he is the culprit who perpetrates the absurdity. He compares an estimate for one thing with the cost of another, and damnifies Bennett accordingly. He fails to distinguish between a similar or an equivalent, and interprets these words as identical. He won't even have approximate, or allow that such a system means aught but an identical system, though the enquiry shows conclusively that Bennett estimated to arrive at the same ends by modified means.

I have done. I am quite willing to leave the conclusion in the hands of the reader.—W. O. T.

ERRATA.

SIR,—Allow me to call attention to two mistakes which occurred in my answer to "E. S. C.'s" question *re* dynamo test. Page 33, line 9, should read:

$$-\frac{d\,E}{dt} = \frac{d\left(\frac{S^2}{2} \times I\right)}{dt} = \text{etc.}$$

The twelfth line and following on the same page should run: "$I\left(\frac{\pi}{30}\right)^2$ is a constant value for any particular machine. The expression $n\frac{dn}{dt}$ represents the subnormal of the n/t curve."—Yours, etc., R. E. C. IHLEE.

WIRE STRIPPING.

SIR,—Can you or any of your readers inform me, through the columns of your paper, of a tool which will remove a small portion of the cotton covering on electrical wires and at the same time clean the exposed wire preparatory to

Digitized by Google

soldering it to a metal connection? I am employed in a large electrical engineers' works, and am anxious to find out a quicker way of cleaning wires than by using a knife to scrape off the cotton and then a small piece of emery cloth to brighten the exposed surface. A tool or power-driven appliance to do this work would save much time if it were used to clean the ends of armature coil sections during the operation of coupling the same to the commutator.—Yours, etc.,

OWEN L ILBERT.

28B, Mildmay-road, Chelmsford, Sept. 14, 1904.

LETTERS FROM AN OLD HAND TO A YOUNG ONE.

VII.—On Going Teaching.

My Dear Young 'Un.—Your last letter betrays the influence which I have been trying to warn you against—perhaps the only bad effect of College life—the aversion to "roughing it." In your case the temptation has presented itself in a very alluring form. You have shown yourself remarkably clever at book work (I had no idea you had it in you). Your Professor is very pleased with you, and has offered you a job as junior demonstrator with opportunity for research. Oughtn't you to take it, and go in for a scientific career?

Now, before answering you directly, it is necessary to say that if some fellows didn't accept such offers there would be fewer technological teachers. Particularly at present there is a demand for men of your type to bridge the gap between primary education and the University College standard. If this is the work that is going to make you satisfied with yourself throughout life, you had better close with the offer. Only you should know what you are going for.

Firstly, your capabilities will be limited. You will have no adequate means of expressing your ideas in practical form. You will be unable to use your hands; you will have no knowledge of practical considerations of economy in machine processes. You will, therefore, be dependent on someone else to bring your ideas to fruition. And experience shows that the money goes to the man who *does*, rather than to the man who *thinks* about doing it. Plenty of machinists make a fat little living out of putting scraps of iron and gunmetal together to the instruction of some inventive genius who can't use his hands. Usually the machinist buys some houses and lives on the rents. The inventor gets a jerry tailor to turn his year-before-last coat outside in—because he likes the pattern so much, you understand, not because it was getting green and greasy.

Secondly, you will be poor. Teaching ought to be paid well, but it isn't. I knew a poor beggar who was a D.Sc., a Ph.D., and various other letters of the alphabet—a man who had discovered six or seven organic compounds with names as long as the faces of the chaps who tried to read them; a savant who wrote learned articles in the scientific papers at about 1½d. a line. Well, that man started teaching at a University College at £100 a year, and in the course of five years he had reached £150! And he had learnt to do without talking about the glorious mission of educating The Young. He knew The Young, and cursed them with all the curses he had learnt at Cambridge and Leipsic. He was careful to point out, when any bold man interrogated him as to why he continued to live, that what he was really hanging around for was a Professorship. A Professor gets anything from £250 to £1,000 a year, and becomes so absorbed in administrative duties that he relegates most of the teaching to his lecturers (at £150). Now, this man had worked out a calculation, and had found that his chance of becoming a Professor was 0·006 in a hundred. The last time I heard of him he was getting discouraged, and was trying to save enough money to go to Monte Carlo and either break the bank or shoot himself.

In the third place, colleges are getting more exacting in their requirements as time goes on. Here are some extracts from the specification of a lectureship in electrical engineering according to modern standards. The lecturer would receive £200 a year, which is a large-sized plum in teaching. Consequently half the teachers in the kingdom would rush at it.

"... He will be required to teach in the electrical engineering classes, ... and perform such other duties as may be assigned from time to time in connection with the work of the department." That is, to rig up apparatus for popular lectures—possibly give one himself gratis if he is big enough; also to enrol students, give free consultative opinions to research students, and so on.

"... The standard of teaching must be equal to that of a University College." Engineering calculus, a hash of the latest articles in the English, German, and French technical papers, and second-hand dynamo design.

"... Candidates should possess workshop experience, and should have received a sound scientific and laboratory training of at least three years in some institution of University rank. Previous teaching experience is essential." So if you went demonstrating now, without getting some workshop practice, you would be barred from this plum of £200.

"Research will be encouraged, and reasonable facilities will be given for it. No outside work may be taken without the permission of the principal. The work will be partly evening class work and partly daywork. The engagement will be terminable by one month's notice on either side, to expire at any time."

My dear fellow, you can do better than this in practice. Even if you don't like dirty work, you can get into an engineering office and play about with drawings and schedules to your heart's content. Remember that although a million people a month can pass a given railway signal box without overcrowding the trains, there is only room for one signalman in the box. If you are a teacher, you will only act as the signalman for the surge of engineers that will pass you by. And it is only so long as the surge continues that your position will be of any value.—Yours,

THE OLD 'UN.

STEAM TRIALS ON WILLANS CONSTANT-THRUST ENGINES AT THE POPLAR AND THE BLACKBURN ELECTRICITY WORKS.

On April 6 steam trials were made at the Poplar electricity works, where Mr. P. N. Hooper is the chief electrical engineer, on one of the 500-kw. Willans engines recently installed, with a view of ascertaining the commercial efficiency of the Willans-Mather and Platt steam sets under working conditions. The trials were carried out under the supervision of Mr. Hooper by representatives of Messrs. Willans and Robinson and Messrs. Mather and Platt, and are of considerable interest at the present time, as showing the results obtainable with this type of engine under working conditions with only a moderate amount of superheat and with a comparatively poor vacuum. It will be noticed in Table A that at full load with a vacuum of 25in. in the engine, and with 25deg. of superheat only, a total steam consumption of 18·64lb. per kilowatt was obtained on one trial and 19·52lb. of steam per kilowatt on a second trial. This means that the mean of the two trials was about 19lb. of steam per kilowatt, or about 11½lb. of steam per indicated horse-power. It will be conceded that these results are very good considering the conditions. It is unnecessary to emphasise the fact that with higher degrees of superheat the steam consumption would have been considerably lower, as this engine benefits to an abnormal extent by the addition of superheated steam. The exhaust steam from the engines was collected and condensed in a tank mounted on a weighbridge, which was measured at definite periods. The electrical instruments recording the output of the dynamo were of the Western standard type, and were calibrated by an independent authority after the tests. The results in the tables herewith are corrected to allow for an error in the instruments, which were found on calibration to be reading rather high.

On May 14, 1904, similar tests were carried out at the Blackburn Corporation electricity works, where Mr. A. S. Giles is the chief electrical engineer. The tests were made with a view of ascertaining the commercial efficiency of the 750-kw. Willans steam dynamos recently installed in conjunction with Dick, Kerr, and Co.'s 10-pole continuous machine, giving an output of approximately 1,600 amperes

Digitized by Google

at 500 volts when running at a speed of 180 revolutions per minute. The trial under consideration at the present time was made on engine 3,416 by representatives of Messrs. Willans and Robinson and Messrs. Dick, Kerr, and Co., under the direct supervision of Mr. Giles. The steam consumption results, which are given in Table B, are the mean results of three separate trials, which, considering the poor vacuum prevailing—viz., 22in.—and the moderate degree of superheat — viz., 112deg. F. — the results obtained—viz, 18 34lb. per kilowatt, say 11·05lb. per indicated horse-power—are distinctly good. The steam consumption was obtained by measuring the water into the boilers, the tank used, which belonged to the station, being calibrated before the trial against a properly calibrated tank. The instruments were of the Western type, calibrated against standards before and after the trial. At the present time engineers are chiefly interesting themselves to a considerable extent in results which are being promised with steam-turbines, and consequently the two results given will be of interest as showing what is possible with reciprocating engines, even in the smaller sizes.

JUNIOR INSTITUTION OF ENGINEERS.

Summer Meeting in Germany.

Perhaps the decision that Germany should be the location of the present summer meeting of this vigorous and useful society may have been regarded by some of its many friends as of too ambitious a character, but the great success of the gathering has justified in a most ample manner the council's selection of the rendezvous. They had, no doubt, counted upon a warm welcome from the German engineers. It was unmistakably so, the members being received with the greatest kindness throughout the extensive tour, which included Düsseldorf, Oberhausen, Benrath, Elberfeld, Hanover, Berlin, Mariendorf, Charlottenburg, Leipsic, Frankfort-on-Maine, Hanau, Homburg, and the Rhine.

The proceedings opened on Aug. 13, when, in the evening, at the fine municipal concert hall at Düsseldorf, the civic authorities tendered greetings on the institution's first entrance to the Fatherland. Associated in the ceremony as hosts were the Institution of German Ironfounders, the Lower Rhine District Association of German Engineers, and the Düsseldorf Institution of Architects and Engineers. Mr. Samuel Cutler, jun., M.I.M.E, the Junior Engineers' genial chairman on this occasion and at other times, gave fluent utterance in the Teutonic tongue to the institution's acknowledgements, as did also Mr. F. R. Durham, A.M.I.E.E., of Frankfort-on-Maine, the indefatigable hon. secretary of the meeting.

The following day was spent in an inspection of the Düsseldorf Exhibition, under the guidance of Mr. Emile Hess, its engineering features, of course, receiving special attention. Next morning an early train was taken for Oberhausen, where are situated the great iron, steel, and engineering works of the Gutehoffnungshutte. Two divisions were formed for visiting them, one proceeding to the blast furnaces, steelworks, rolling mills, etc., the other to the steel, iron, and metal foundries, engine and bridge works, etc. There appeared to be plenty of work under execution, and an extensive addition to the rolling mill was in course of building. After being entertained to luncheon in the works' clubhouse, the members went on to the Benrather Crane Works, which is one of the largest of its kind in Europe and has attained such a well-merited reputation for the excellence of its products. Both steam and electricity are employed as motive power. The methods of testing the various parts, systems of erection, and other details were fully explained to the visitors.

On leaving Düsseldorf the party made for Elberfeld for the purpose of seeing the Langen Monorail Suspended Electric Railway, which presents so many novel points of engineering interest. In this system the carriages are hung and travel from an overhead rail, which may be fixed at any level above ground, or may be carried along the roof of a brick tunnel or iron tube. Another example occurs at Loschwitz, near Dresden. The Elberfeld line has a length of 8¼ miles, and has been in operation since March, 1901. It now carries about 10 million passengers per annum. Under the guidance of the engineers a complete inspection of the line was made, including car-sheds, power-house (current is supplied from the municipal works), stations, etc.

In the afternoon the members arrived at Hanover, where on the next day the first visit was to Messrs. Korting Bros.' works, erected in the year 1871, and now giving employment to 2,500 hands. The chief products are gas-engines, appliances for steam users and manufacturers, pumps, boilers for steam and water heating, radiators, etc. Some special experiments with Korting injectors, steam-jet elevators, condensers, blowers, pulsators, etc., were carried out. The Korting ejector condenser is well known in England, over 50 electric light and power stations being fitted with it. An interesting application of the spray nozzle was illustrated as it would be employed in cooling condenser water. It was also applicable to laying dust in colliery workings, purifying air of public buildings, damping tobacco, etc, cleaning blast and producer gases. Some powerful gas-engines were seen in the erecting shop, both of the Otto and the Clerk cycle. The former are built up to 200 h.p. in one cylinder and the latter single-acting up to 300 h.p., or double-acting up to 1,500 h.p. in one cylinder. The largest installation (40,000 h.p.) of the Korting double-acting Clerk cycle engine is at the Lackawanna Steelworks. The importance of the heating engineering department of Messrs. Korting may be gathered from the fact that annually 5,500 tons of castings, 1,500 tons of wrought-iron tubes, and 33,000 valves are made use of. Hospitable entertainment followed the visit, and the Hanover Engine Works were then inspected. These were founded in 1835, and have developed to such an extent that about 2,000 workmen are now employed. The manufacture of locomotives forms the principal work carried on, that department having been started in 1846. The total output to date has been close on 4,300, and 40 engines can be fitted up simultaneously. The electric central station, with engines of 1,500 i.h.p., attracted special attention, and various processes with heavy tools, etc., were arranged to be going on during the members' tour of the works. The toast of the "Hannoversche Maschineban" having been observed on leaving, the members then made their way to the Westinghouse Brake Company's works, the construction and operation of the brake being fully explained with the aid of an experimental apparatus such as is installed at the London depôt, King's Cross. The Hanover Gasworks were then entered so that the Paris electro-turbine gas retort charging machine might be seen at work. The rapidity of its action was most striking, but as the machine has only just been introduced, it is not possible to give definite results of its working at Hanover for any length of time. In carriages which were kindly provided by Mr. L. Korting, the engineer of the works, and who, by the way, is president of the German Association of Gas and Water Engineers this year, the members then had a most enjoyable drive to Herrenhausen; the fountain display, a notable feature

Digitized by Google

of the beautiful grounds, was seen. Mr. Korting also acted as cicerone to the members on the following morning, when the zoological gardens, provincial museum, and other places were visited. In the afternoon came the journey to Berlin, which was reached at about seven o'clock.

Friday morning was occupied by a most interesting visit to the Berlin electric overhead and underground railway and to the works of Messrs. Siemens and Halske. Assembling at the Potsdamer Platz Station of the railway, the party were met by the engineers and taken by train to the terminus of the line, Warschauer Brucke. The car depôt and workshops were shown, and after proceeding by rail from Schleischer Thor to Mockern Brucke, the members walked over the bridge to the power station of the railway. The plant here consists of three Borsig engines of 1,200 h.p. maximum, and an engine of 1,800 h.p. by the Gorlitzer Maschinenfabrik. The dynamos are directly coupled to the engines, and are shunt generators for 800 kw. at 750 volts, constructed by Siemens and Halske. After going through the junction triangle, the party took train again to the terminus of the line and at the Students' Union Club at Charlottenburg were entertained to luncheon by Messrs. Siemens and Halske, their works being visited in the afternoon. In the large machine shop of the works the preparation and mounting of the various parts of dynamos, motors, etc., was seen. Other shops were occupied with resistances, starting and regulating resistances, apparatus for lifts, and accessories for lifts and cranes, switchboards and switches, high-current apparatus, switches, cut-outs, and line articles. The manufacture of arc lamps was also shown, and in the testing-room a highly interesting collection of different types of lamps were seen running. The institution's summer dinner was successfully held in the evening at the Central Hotel, Berlin, the opportunity being taken for presenting to Mr. Durham a leather writing case suitably inscribed in expression of the members' appreciation of his valuable services as hon. secretary.

On the following day the Mariendorf gasworks of the Imperial Continental Gas Association were visited in the morning, and the Royal Technical High School at Charlottenburg in the afternoon. The gasworks are of the most modern description, and afforded the members an excellent example of the latest practice in that class of work, having been completed as recently as the autumn of 1901. Special features consist of the coal-handling plant, inclined retorts, coke-conveying machinery, naphthaline washer, cyanogen washer, overhead loading station for the tar, ammoniacal liquor, etc. A new holder was seen in course of erection by the Berlin Anhaltische Company. The whole of the side sheets are to be riveted by pneumatic riveters, air-compressing plant having been put down for the purpose. At the Charlottenburg School, where, unfortunately, there were no technical guides to show the members round, perhaps the most striking feature was the large laboratory containing representative gas, oil, and steam engines of every type, aggregating over 800 h.p., with corresponding boiler power, by means of which the students could test under actual working conditions every kind of motive-power plant. This visit concluded the programme of the first week.

On Monday afternoon, Aug. 22, the party left Berlin for Leipsic, remaining there till Wednesday, when they went on to Frankfort-on-Maine. On the invitation and under the guidance of Mr. W. H. Lindley, M.I.C.E., an English engineer who has achieved great distinction on the Continent, the water and electricity works at Frankfort and the sewage works at Hanau, all of which were designed and carried out by him, were inspected. The arrangements made for these visits were most excellent, and might well be followed in this country. Previous to the members going over each works Mr. Lindley, with the aid of diagrams and drawings, gave a general description in the form of a short lecture. Members were thus in possession of the general characteristics of the undertaking, and in a much better position for seeking any special information having reference to their own branch of work. A fact which may not generally be known, which was elicited in the course of the visit, is that to Mr. Lindley is really due the introduction into Germany of the Parsons steam-turbine of large power.

An excursion to Homburg took place on Friday afternoon, when the director of the baths conducted the members over the old and new buildings, where baths of every description are obtainable. The eight mineral springs were also seen, and the pumping plant for raising the water for use in the baths. On the historic Kurhaus terrace dinner was served in the evening, followed later by the fireworks of the annual summer festival. It was a delightful experience altogether. The next day the members travelled by train from Frankfort to Biebrich to join the Rhine express steamer for the trip to Bonn, and thence by train to Cologne, and so on to Flushing and England. It should be mentioned that two extra visits occurred, one at Berlin to Mr. W. Pittler's experimental works and the other to Messrs. Pittler's lathe works at Leipsic.

EAST HAM ELECTRICITY ACCOUNTS.

From the recently published accounts of the Urban District Council's electricity works herewith are given abstracts of the revenue account and balance sheet for the year ended March 31, 1904, also a statement of electricity generated, sold, etc. The capital expenditure to date amounted to £97,154.

REVENUE ACCOUNT.

Dr. Expenditure.	£	s.	d.
Generation of electricity	7,438	7	0
Distribution of electricity	350	9	7
Public lamps	984	18	7
Incandescent lamps for artisans' dwellings	7	3	5
Management	611	9	10
Rates, taxes, and insurance	388	7	3
Bad debts	121	3	7
Gross profit, carried to net revenue account	8,583	7	0

TRADE NOTICES AND NOVELTIES.

Wirt Rheostats.

Of the divers types of dynamo field and other rheostats now on the market, that bearing the name "Wirt" ranks high for ingenuity of design and reliability in working. It is one of the many useful devices for which we are, in the first place, indebted to American inventive genius. Referring to the first of the accompanying illustrations, it will be seen that the resistance material is employed in the form of a continuous ribbon, wound without break or joint into the desired number of steps. This ribbon is tapered in such a manner as to give the proper ampere capacity at each point, while still maintaining the continuity, whereby the necessity of introducing a twisted or soldered joint at every step where it is desired to change the size of the ribbon or resistance wire is entirely obviated. The resistance coils make direct contact with the commutator bars, the area of such contact being very great and absolutely positive. Moreover, the commutator bars are graded so that each bar has an area of contact with its corresponding coil, varying in proportion to the current to be carried. Mica is used exclusively as insulation. The resistance coils, with their accompanying commutator bars and mica discs, are placed between two metal plates, the back one of pressed steel, the front one of cast iron. These plates are held firmly together by means of a steel rim-band. Thus the resistance ribbon lies flat against the radiating plates, the only intervening substance being a thin sheet of insulating mica. This construction permits the heat to be most readily conducted to the external surface, and thence dissipated. The result is that the resistance material always runs comparatively cool, a condition which best fortifies it against injury in case of an accidental overload. Besides, the method of distributing the heat by tapering the resistance and grading the steps enables each plate to work at its maximum efficiency, and therefore permits a heavier load for the size of the plate than is possible under any other condition. The graded commutator bars, extended radially, are exposed at the inner end for contact with the switch. They are trued up at this end by mean of a centre porcelain disc, which ensures a smooth commutator for the switch to pass over. The switch itself, of spring phosphor bronze, makes connection with the centre ring and the commutator section upon which it is placed. This avoids passing current through the bearings. Fig. 2 herewith will serve as an aid to the above description, and at the same time speak for the compactness of the complete apparatus. Apart from field rheostats, the same principle has been applied with equal success for theatre dimmers, speed controllers, etc. It remains to add, in conclusion, that Messrs. J. Defries and Sons, Limited, 146 and 147, Houndsditch, London, E.C., are the sole licensees and makers of the apparatus in this country.

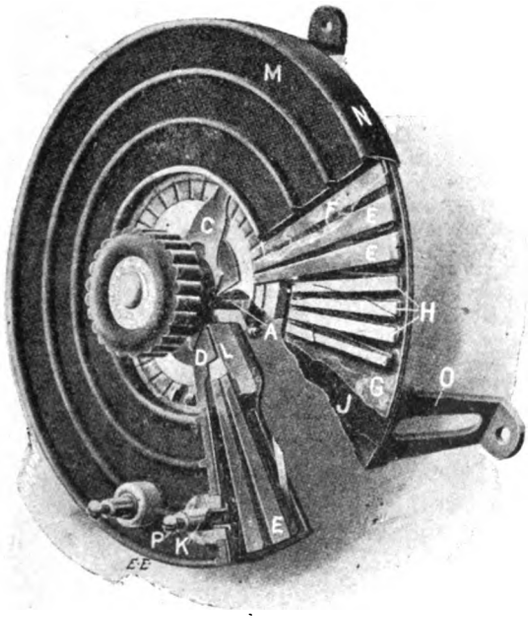

FIG. 2.—"Wirt" Field Rheostat. C, Switch Blade; D, Centre Contact, in one piece and rivetted to binding post K; F and G, Mica Insulation; J, Case Plate; H, Resistance Ribbon; L, Porcelain Block: N, Rim-Band.

The Ondograph.

We are indebted to the British Thomson-Houston Company, Limited, Rugby, for the following description of a new recording instrument which they are introducing, called the ondograph. This instrument has been designed for service in the study of alternating-current phenomena, and will register waves directly upon a sheet of paper within the space of half a minute. In principle the instrument is based, to a large extent, upon the well-known Joubert method of plotting alternating-current waves by means of a momentary contact obtained by a revolving commutator. A clear idea of the principle on which the ondograph works will be gained from a study of the accompanying illustrations, Figs. 1 and 2. A synchronous motor of the alternating-current type is operated from a source of current the wave of which it is desired to take. The motor is provided with gearing which operates a revolving commutator, the speed of which is so regulated that while the motor makes a certain number of revolutions the commutator makes a like number increased or diminished by unity. The motor in this case makes 1,000 revolutions while the commutator makes 999, thus causing the instrument to indicate a complete wave at every 1,000 revolutions. The commutator is used for the purpose of making automatic connections with the condenser and the galvanometer. It consists of an ebonite cylinder carrying a

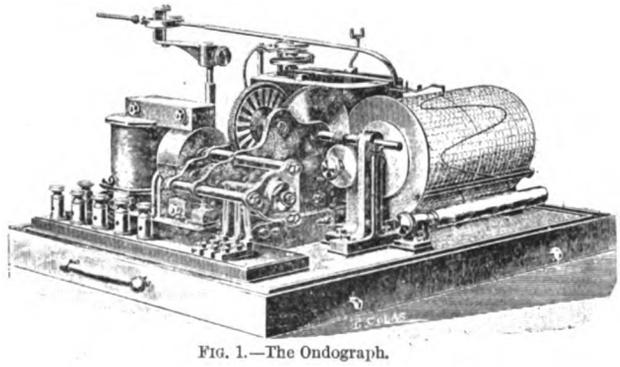

FIG. 1.—The Ondograph.

Digitized by Google

brass tube cut out in the form shown in Fig. 3, and has three brushes bearing against it. The brushes are connected with the condenser, C, and a galvanometer, I, while at A are the main terminals of the circuit whose wave is to be taken. M is the metallic part of the commutator. As the commutator revolves the condenser is first put on the main circuit for an instant, then the condenser terminals are connected for a like period with the galvanometer, and the latter thus receives the discharges of the condenser and indicates the voltage at which the condenser has been charged. As this voltage increases and diminishes throughout the 1,000 revolutions, the galvanometer needle swings slowly back and forth and shows the voltage variations corresponding with a complete cycle. By changing the capacity of the condenser the sensitiveness of the indicator

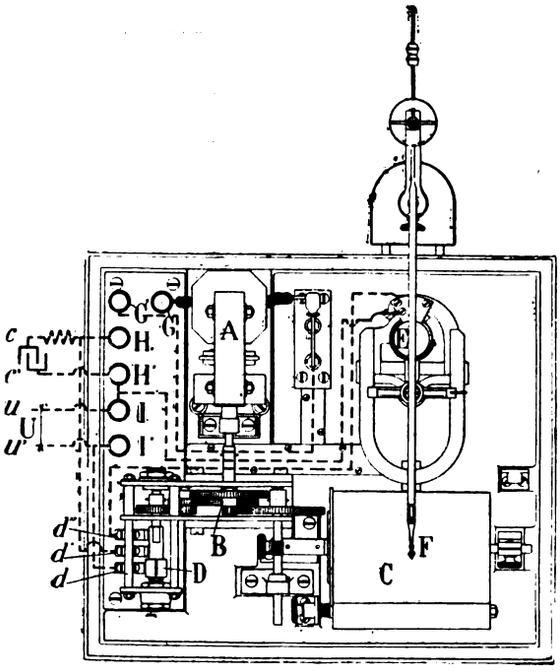

FIG. 2.—Plan of Ondograph.

can be regulated. In Fig. 2, G G′ represents the terminals of the motor, which also receives the current of the main circuit, and works at 110 volts, the latter being obtained, if necessary, by a regulating transformer. The terminals, H H′, are connected to the condenser, *c c′*, through a resistance which is sufficient to avoid sparks at the charging brushes. I I′ are the terminals of the main circuit which receives the voltage, U, to be taken. The synchronous motor makes a number of revolutions per minute which correspond to one-half of the frequency of the main circuit. At D is the commutator with its three brushes, *d d′ d″*. The indicating instrument for voltage or current wave is a galvanometer with a permanent magnet and rectangular current coil of fine wire mounted between the poles. The movable part, E, receives the discharges of the condenser in rapid succession, and turns slowly from one side to the other, passing through the zero position. The movable part operates a long needle which carries a pen, F, which swings to and fro, tracing the curve upon a revolving cylinder. The needle is not mounted directly upon the coil of the galvanometer, but, in order to use as long a needle as possible, and thus make it move nearly in a straight line, it has its pivot fixed considerably in the rear, while the coil has a short arm which works the needle by a projection passing in a slot. The record is made upon a sheet of paper which is rolled upon the revolving

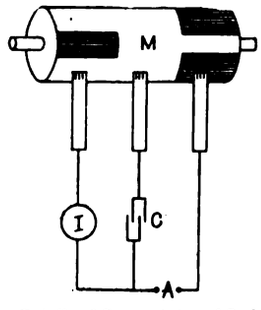

FIG. 3.—Details of Commutator of Ondograph.

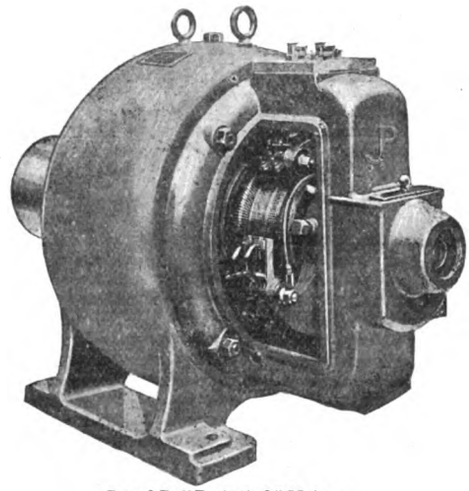
cylinder. The cylinder is operated by the synchronous motor, by gearing, at a speed which makes it register three complete waves upon its circumference. The ondograph is the first instrument by which watt curves can be registered directly. For this purpose the permanent magnet form is replaced by a wattmeter carrying a set of fixed coils, which act upon a swinging armature of fine-wire coil. The current traverses the fixed coils continuously, while the movable coil is placed in the voltage circuit. The regulation is carried out by an ohmic resistance, which is placed in the circuit of the movable coils. The Thomson meter is found to be the most satisfactory form of wattmeter for this purpose. Two spiral springs for carrying the current are attached to the armature shaft, and therefore no brushes are used. The main current passes through the fixed coils, and the movable coil is actuated once every period for a short time with the voltage circuit. For use with the wattmeter the revolving commutator is reduced to a simple strip placed along the ebonite cylinder, which closes the circuit through the movable coils once every revolution. Under the influence of the successive impulses in the movable coils, it reacts upon the fixed coils, and takes an angle which corresponds to the power at each instant of the period, and therefore traces the watt curve directly upon the paper. The ondograph may also be used to study continuous currents. To accomplish this the synchronous motor is replaced by a direct drive effected by establishing an unyielding mechanical coupling between the ondograph and the shaft of the machine to be studied. The instrument has been specially designed with a view to facilitating the removal and replacement of the motor. The application of the instrument is not limited to periodic phenomena. It can be extended to all phenomena of short duration, provided that the phenomenon can be reproduced to such a manner that it is periodic by repetition.

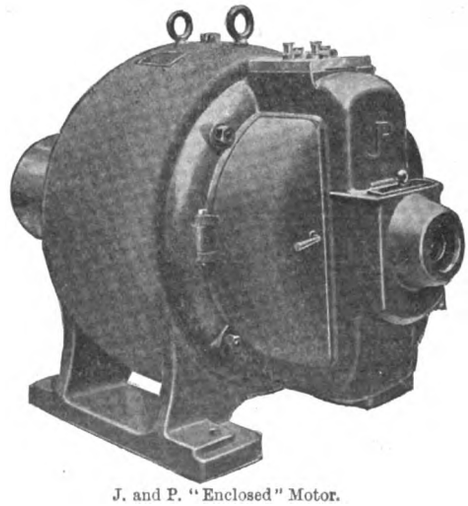
J. and P. Electric Motors.

Messrs. Johnson and Phillips, Old Charlton, Kent, have recently issued a revised price-list of their direct-current electric motors. These motors, we are told, are designed on a uniform plan, from ¼ h.p. up to 100 h.p., with their speeds properly



J. and P. "Protected" Motor.

graded according to the horse-power, and as dictated by the most advanced theoretical and practical considerations. They are made to the standards issued by the Engineering Standards Committee in four classes — viz., "Open," "Protected," "Ventilated," and "Enclosed." A specification applying to



J. and P. "Enclosed" Motor.

all J. and P. direct-current motors is included in the list, the many excellent features of their design being fully enumerated therein. As regards the outward appearance of these motors, we may leave the accompanying illustrations of the "Protected" and "Enclosed" classes respectively to speak for themselves.

DUBLIN ELECTRICITY WORKS.

The following is a report by Mr. Hammond, the consulting engineer for the new Dublin electricity station, upon the working of the same for the past 12 months. The report is dated Aug. 25 last, and addressed to the town clerk:

DEAR SIR,—The agreement entered into with me by the City Council for the supervision of the operations of their electric supply undertaking for a period of 12 months came to an end on the 31st ult. I am glad to feel at the conclusion of the 12 months that the work therounder has proved so successful, and that, since the staff settled down to their duties, there has not been a single cessation of the city lighting. It has been a great satisfaction to me to have had so excellent an opportunity of demonstrating the practicability of the new system, which, at its inception, was so derided. I do not desire to minimise the boldness which characterised the Dublin Corporation in their adoption of my recommendation of a system of electrical distribution which had never before been attempted in the United Kingdom, and the members of the City Council will, I am sure, share my pleasure in reporting that in the actual working of the new system there has not been a single hitch, and it has proved simple, flexible, safe, reliable, and economical. In relinquishing the task of supervision, it occurs to me that the Corporation may desire to receive from me a short report of my stewardship. The Council passed the resolution conferring the appointment upon me on July 29, 1903. On the following day I started the work thereunder, and since that date either I or other members of my firm have been in regular attendance in Dublin.

Staff.—The first matter to which I had to devote my attention was the appointment and organisation of the technical and general staff for working the new undertaking, which demanded mature consideration. On Sept. 6, 1903, I was able to submit to the Lighting Committee a schedule of the first appointments grouped under the following heads: (*a*) generating department; (*b*) distributing department—(1) Fleet-street station, (2) distributing system; (*c*) public lighting; (*d*) office staff. It will be remembered that prior to entering into the agreement to supervise the working of the undertaking for 12 months I made it a *sine qua non* that I should be absolutely unfettered in the choice of staff, with power to appoint and to dismiss. That power was conceded to me by the Council, after a pledge on my part to give preference to Irishmen wherever possible. I have to report that at the outset I took over the whole of the old staff. Obviously, however, this staff was not numerous enough for the greatly enlarged undertaking. A word here may be acceptable as to the work to be performed by the staff. The electrical energy is generated at Pigeon House, and it is thence transported by three trunk mains to Fleet-street, whence it is distributed to the various sub-stations throughout the city. At the sub-stations it is transformed "automatically" from high pressure to low pressure without the use of any moving machinery. From the sub-stations it is distributed throughout the streets in the new area of supply—namely, the area outside that in which the supply was formerly given from the Fleet-street works. At Fleet-street a portion of the Pigeon House current is used for driving machines which feed the arc lights, which can, therefore, be turned on and off at Fleet-street. It will be seen, therefore, that provision had to be made first for a staff to run the much larger generating works at Pigeon House, involving three shifts of men and electricians-in-charge, each working eight hours. Then provision had to be made for the operations at Fleet-street, also involving three shifts of men and their electricians-in-charge. Then the 20 sub-stations had to be regularly inspected and a staff arranged for taking charge of the distributing mains and making connections to new consumers all clamouring to be first served. In addition, the 488 arc lamps had to be carboned regularly. It will be seen, therefore, that I had placed upon me an onerous task in the selection of the new men. Needless to say that I bore in mind my pledge to the Council, and, in this connection, I desire to set forth an extract from my report to the Lighting Committee of April 30, 1904:

"It has been stated, much to my surprise, that the new appointments have been given to Englishmen in preference to Irishmen, and I desire to take this opportunity, therefore, of saying that such statements are absolutely unfounded. As a matter of fact the reverse has been the case, and in making the appointments, where the necessary qualifications for the posts were assured, preference has been given in every case to Irishmen. Apart from the old staff, all the members of which were taken over, some 16 new appointments have been made on the engineering staff, of which 14 were given to Irishmen and two to Englishmen. The two exceptions were the cases of the distributing engineer, in which the committee themselves considered that it was of great importance to appoint the gentleman who had had all the experience of superintending the laying of the mains, and of the works superintendent at Pigeon House, in which case special experience with large plants on polyphase systems was an indispensable condition. All the other appointments are now filled by Irishmen and by the old staff. The statement to which I have referred caused me great personal disappointment, as it had been a source of gratification to me that I had been able to bring back from England and Scotland several young Irishmen, and most of them Dublin men, who, having obtained sound experience across the water, were glad to have the opportunity of taking an appointment in their native country."

When the staff was finally selected for the respective duties, I notified all the members that the arrangements which were then made were of a provisional nature, and that their positions and ultimate remunerations would be taken into consideration after experience had been obtained of the manner in which their duties were performed and of the value of their services to the undertaking. Accordingly, I, in due course, was able to make various rearrangements to add to the staff in certain directions as the different parts of the undertaking were taken over from the contractors. A full list of the complete staff, with the salaries fixed by me, has been recently handed by me to the Lighting Committee. The chief of the separate departments acting under the city electrical engineer are: office department — Mr. G. Archer, chief assistant; distributing system—Mr. E. A. Ellicott, distributing engineer; generating works—Mr. R. Knowles, works superintendent. Upon these gentlemen a large responsibility rests, and I consider that they are entitled to high commendation for the excellent way in which their departments have been controlled, especially during the period when they were deprived of Mr. Ruddle's guidance by his absence through illness. I must pay a special tribute to the efficient manner in which Mr. Archer managed the undertaking as Mr. Ruddle's deputy. I desire also to add a word in favour of Mr. Chas. Clancy, the assistant distributing engineer, who, during Mr. Ellicott's illness, acted as the chief of the distributing system with conspicuous ability. Other members of the staff, too, have carried out their duties in a highly capable manner, and I am glad to be able to speak with satisfaction as to the smooth working of the whole of the staff.

Residential Quarters for Staff.—In order to assure the presence at the generating works at all hours of certain members of the staff, residential quarters have, with the kind assistance of the Improvements Committee, been provided at Pigeon House for a few of the men, and these have been readily taken up. It would be an advantage if still further accommodation in this direction could be provided, and I repeat the suggestion made in my report to the Lighting Committee of July 25 last, that negotiations towards this end be opened with the Improvement Committee, who have charge of the premises at Pigeon House.

Change-over of System.—After the appointment of the staff, the most pressing work was the arrangement for the changing over of the supply from the old Fleet-street works to the Pigeon House works. This was the rock upon which our critics urged that we should suffer shipwreck. The new system employs three-phase 5,000-volt feeders with 50 periods. The old one was single-phase 2,000-volt with 84 periods. Under the new scheme there are provided at Fleet-street transformers to reduce the 5,000 volts pressure to 2,000 volts, and these transformers under the new scheme take the place of the generators in the old. I am glad to be able to report that the change-over was most successfully effected on Sept. 20, 1903, without the slightest inconvenience to the consumers; indeed, with hardly a blink on the lights. Though the Fleet-street plant was kept as a stand-by for a short time, it was never once used.

Administrative Department and Consumers' Records.—On turning my attention to the internal organisation of the administrative department, at Fleet-street I found that a considerable alteration was necessary in the method of dealing with the technical records of consumers and their installations. At the time of my appointment the system of these records was not suited to the requirements of a large business, and I therefore considered it necessary to arrange a new plan of records for the undertaking on the card system, the most modern method of dealing with consumers and meter records, this being on similar lines to that which I have adopted with great success in other cases. I am glad to be able to report that it is working most successfully. The system which has been specially devised for Dublin, so as to suit the special tariff of charges and the three-phase system, embraces the following: consumers' index cards—an index for the complete system; meter-reading cards, upon which the meter readers record the registrations of the meters and indicators; consumers' ledger cards, upon which the details, technical and financial, of the consumers' quarterly accounts are set forth, these cards being regularly transmitted to the city accountant's department for the purpose of making-up the quarterly bills and for entering into the consumers' ledger; ledger cards (general charges) dealing with private works and small works executed by the department for consumers, etc., other than for electricity supplied; installation cards, upon which all the technical records of each consumer's installation, including tests, number of lamps, etc., are recorded; balancing

Digitized by Google

cards for entering up the demands in each street so as to enable the engineer to preserve a good balance of the load on the mains; meter test-cards for recording particulars of each meter with results of its tests and its position from time to time on the circuits; demand indicator test-cards for exactly similar purposes to those of the meter test-cards; guide cards for the complete system by which the separate sections and classes are arranged for easy reference; cabinets embracing five special cabinets for filing the card records.

Supplies.—In systematising the purchase of supplies, I have, through the Supplies Committee, introduced the plan of inviting tenders to rigid specifications for coal, oil, and carbons with eminently satisfactory results, the recent contract for delivery of coal at the wharf at Pigeon House to my specification being made at the favourable rate of 9s. 2d. per ton. The tenders for machinery oils have also been productive of significant figures, with the result that first-rate oils will be obtainable under my specification at considerably lower prices than those which have hitherto been paid by the department.

General Management of Undertaking.—The arrangements for dealing with existing and prospective consumers are, in my opinion, incompatible with the requirements of a large system of electric supply, and I feel that they could be vastly improved by centralising the authority for this branch of the business at Cork-hill. It would, I consider, be wise to centralise the entire responsibility of the business part of the undertaking upon the secretary to the committee instead of leaving it divided as at present, and to make the committee offices at Cork-hill the office of enquiry and reference, leaving the administration at Fleet-street to deal with the technical side of the undertaking. I think it might also be advisable that some arrangement should be adopted by which the accounts of the undertaking should be kept at the committee offices, so that easy reference could be made thereto, and the consumers saved the trouble and inconvenience which the present system entails.

Consumers.—The connecting on of new consumers has, under the new arrangements, proceeded smoothly and rapidly, the number having been considerably more than doubled within the first year. The following is a monthly record of the consumers for the past 12 months: July 1, 1903, 350 consumers; Aug. 1, 373; Sept. 1, 409; Oct. 1, 482; Nov. 1, 551; Dec. 1, 608; Jan. 1, 1904, 665; Feb. 1, 676; March 1, 708; April 1, 734; May 1, 754; June 1, 767; July 1, 790 consumers. At July 1, 1903, there were 35,791 lamps connected to the mains, at July 1, 1904, the number had increased to 68,322. Applications for supply still continue to come in steadily from ordinary consumers, and, in addition, the Lighting Committee are in negotiation for the supply of electricity to a number of the Government offices, several of the city hospitals, the Richmond District Lunatic Asylum, the North and South Dublin Unions, and other institutions.

Working Costs and Financial Results.—The accounts of the undertaking, which have recently been published, are made up to March 31 last, but as this period covered 3½ months running of the Fleet-street works alone, 2½ months of the Pigeon House works and the old works simultaneously, and only six months of the working of the new undertaking in the early portion of which the Fleet-street works were being kept as a stand-by, the results therein shown are no guide to what will be the result for future years. I am glad to report, however, that even for this period, with all the initial charges incidental to the starting of a large scheme, the cost of working was considerably reduced, the total amount, exclusive of the special fee paid to me under the supervision agreement, being 2·43d. per unit, as compared with 3·09d. per unit for the previous 12 months, and 3·75d. per unit for the year 1901-2. Notwithstanding adverse public criticism and the frequently-quoted report made by Mr. Ruddle in March, 1901, in which he stated that the average cost of production and distribution for the first seven years would be 2½d. per unit, I have no hesitation in stating that the operations of the new undertaking have convinced me of the soundness of the estimate made by me in my original report of the possibility of generating and delivering electrical energy in Dublin at a cost, exclusive of capital charges, of 1½d. per unit.

Now that the undertaking has been so well established, and is giving evidence of such success, I presume that it is unlikely that the Corporation would care to continue leaving the working of the undertaking in my hands. If, however, there be those who are persuaded by the pessimistic criticisms which are in some quarters still rife that the undertaking cannot be worked within the above-named estimate, I desire to state that I am prepared to submit to the Municipal Council the terms of an arrangement for taking control of the working operations, and assuring the Council for a period of seven years against a higher cost than the 1½d. per unit, my remuneration for my supervision and for my guarantee being the difference between 1½d. per unit and the lowest figure at which I may be able to generate and distribute, no special fee for my supervision or guarantee being paid to me at all. I can quite understand that such an offer may not commend itself to those councillors and ratepayers who have formed the idea that the capital expenditure has been out of all proportion to the extent of the undertaking, and that even if the electrical energy can be generated and distributed at 1½d. per unit, the interest and sinking fund charges upon the present capital and upon that which will be required from time to time as the business develops will far exceed the profit on working, and leave a heavy annual deficit to be borne by the ratepayers. Under these circumstances, and having regard to the other financial obligations which the progress of the city has placed upon them, the Municipal Council may feel inclined to enter into an agreement by which they would be relieved of the capital charges on the electricity undertaking for a period of years. In this event I shall be prepared, as an alternative offer to that named above, to place before them the terms of an arrangement for taking over the working of the entire undertaking for a period of not less than 14 years, and for substantially guaranteeing to the Council for that period the annual charges upon the loans raised or to be raised for the purposes of the undertaking, including the productive proportion of the Fleet-street works, the Clontarf scheme, and all extensions of the electric supply system. This arrangement would, of course, include a guarantee that the supply would be provided at rates to be mutually agreed upon, which would certainly not be higher than those at present in force. Under my first offer the Council would be relieved of all anxiety with regard to the working expenses. Under my second offer they would, by parting with the working of the undertaking for only a limited period, be relieved of all responsibility for the capital charges during the earlier years of the undertaking, while at the same time the citizens of Dublin would be assured of a supply of electricity at favourable prices. Whether, however, my offers be accepted or not, I am glad at the close of my 12 months' supervision to be able to hand over to the city a concern that has for many months past been performing its work most satisfactorily from the point of view of the consumer and of the general public. It is true that in my capacity of consulting engineer to the undertaking, it is my duty in certain directions to withhold certificates of satisfaction with some of the plant. The defects, however, have not interfered with the regular supply of electricity continuously for 24 hours per day, and my offers to work the concern are, perhaps, the best evidence which I can give of my conviction that in every direction the contracts arranged by me are sufficiently clear and stringent to obtain, at no extra expense to the city, plant in accordance with the best modern practice.

In conclusion, I have to record my thanks for the assistance which I have received from the chairman and members of the Lighting Committee, and from the officials of the Corporation.

PERSONAL.

Mr. A. E. le Rossignol has resigned his position as engineer and general manager of the Newcastle electric tramways for an important and lucrative appointment abroad.

The Aberdeen Council have increased by £25 the salary of Mr. D. Mooney, superintendent of the Corporation tramways.

LEGAL INTELLIGENCE.

THE SPEED OF TRAMCARS.

On Friday last, at Middlesbrough Police Court, a car driver in the employ of the Imperial Tramways Company, Limited, was charged with having driven a tramcar at a speed exceeding eight miles an hour. The town clerk prosecuted on behalf of the Corporation, and Mr. F. Rowlands defended. The case was heard on Aug. 26, and adjourned for the purpose of the Corporation producing other evidence, as reported in these columns.

Inspector Millstone and **Sergeant Blakeborough** (who used stop-watches) declared that defendant was travelling at a speed of over 16 miles an hour.

Defendant went into the box, and denied that he was travelling at an excessive speed.

A fine of £3, including costs, was imposed.

OVERCROWDING.

At Norwich Guildhall last week Robert Beaumont, a tram conductor in the employ of the Norwich Electric Tramways Company, was summoned at the instigation of the chief constable for allowing an excessive number of passengers. He was further summoned for allowing certain persons, not being officers or servants of the company, to ride on the car platform on the same date.

The chief constable appeared in support of the information; Mr. E. Reeve defended. Defendant pleaded not guilty to each offence.

It appeared that the company had communicated with the Corporation as to carring extra passengers upon special occasions, but had not received a reply. The traffic on the day in question was very heavy.

The **Chairman**, after consultation with his colleagues, said they must convict on each charge, but as there were exceptional circum-

Digitized by Google

stances, only a nominal fine would be imposed. The company's officers had endeavoured to prevent overcrowding. A fine of 1s. in each case would be imposed and costs.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Tynemouth.—The Corporation invite tenders for a 600-kw. steam dynamo by Sept. 30. See advertisement.

Oviedo (Spain).—The Municipality require tenders for the public lighting of the town for 20 years. Tenders by Sept. 20.

Salford.—The Electricity Committee invite tenders for paper-insulated cables. Tenders to the Town Clerk by Oct. 6.

Madrid.—Tenders are required by the Municipality for a number of lamp-posts for one, three, and five lamps. Tenders by Sept. 21.

Arenas de San Pedro (Spain).—The Municipality require tenders for the electric lighting of the town for eight years. Tenders by Sept. 25.

Pretoria.—The Commanding Royal Engineer at Army Head quarters, Pretoria, is calling for tenders for the electric lighting of cantonments.

Mexico.—The Federal District Railway Company of Mexico require tenders for the electrification of six tramway lines in the town. Applications are to be made direct.

Pangbourne.—Tenders are required for lighting the village during the coming winter, for the Pangbourne Parish Council. Particulars may be obtained of Mr. C. West, jun., clerk.

The Hague (Holland).—The Council of the Hague require tenders for the supply of from 8,000 to 9,000 tons of steel rails, including appurtenances, for electric tramways. Tenders by Sept. 2 .

Arenas de S. Pedro (Spain).—The municipality require tenders for electric lighting for eight years. One hundred 10-c.p. lamps are required for public lighting. Tenders by 25th inst. to above.

Edmonton.—The Urban District Council desire to enter into an arrangement with a company for the exercise of their powers under their provisional order. Tenders by Sept. 27. See advertisement.

Ilford.—The Urban District Council invite tenders for the supply and erection of balancer and switchboard panel, and reversible traction booster and switchboard panel. Tenders by Oct. 4. See advertisement.

Belmez (Spain).—The Municipality require tenders for electric lighting of Belmez, Pueblo Nuevo del Terrible, and Pennarroya for seven years by Sept. 17. Particulars from the Alcadia Constitutional, Belmez, Cordoba, Spain.

Aberdeen.—The Tramways Committee invite tenders for the supply and delivery of 20 top-deck car-covers. Drawings and specifications may be had from Mr. J. Alex. Bell, city electrical engineer, Aberdeen. Tenders by Sept. 27. See advertisement.

La Paz (Bolivia).—The Municipality require tenders for the electric lighting of the town for 12 years. There is an old central station and water power of 150 h.p. to 200 h.p., which is sufficient for the number of lamps required. Tenders by Jan. 15, 1905.

Sofia.—The District Finance Commissioners require tenders for 50,000 km. 4mm. iron wire, 1 000 km. 2mm. iron wire, 15,000 Parphor insulators (No. 2), and 1,000 iron hooks (No. 2). Five per cent. guarantee required. Estimate. £1,175. Tenders by Sept. 25.

London, S.W.—The London County Council invite tenders for the manufacture, delivery, and erection of three electric car traversers at certain of the Council's tramway depôts in the South of London. Specification, etc., may be obtained at the County Hall, Spring-gardens, S.W. Tenders by 10 a.m. on Oct. 4.

Rochdale.—The Tramways Committee require tenders for the wiring of car depôt. Applications, with £1. 1s. deposit, to Mr. C. C. Atchison, borough and tramways electrical engineer, Rochdale. Extra copies 5s. each. Tenders, endorsed "Car Depôt Wiring," to be addressed to the Town Clerk, Town Hall, Rochdale.

Philippopolis (Roumelia).—The Municipality requires tenders for a concession to construct and work electric lighting and tramways for 50 years. A guarantee of £6,000 is required. Tenders by Oct. 15. On the next day a second adjudication will take place in case there is an offer of £5 per cent. less per kilowatt-hour than the minimum.

Edinburgh.—Tenders will be received for the supply of 600 tons (more or less) of cable ropes, for the Edinburgh and District Tramways Company, Limited. Specification may be obtained of Mr. John E. Pitcairn, general manager, 1, South Charlotte-street, Edinburgh, and tenders must be lodged with him in accordance with specification by Sept. 19.

Tschatschak (Servia).—The Electricity Company Owtschar und Kablar in this town require two turbines of 750 h.p. each, two generators for three-phase currents, and other plant for the erection of a hydro-electric central station. and equipment of lines of distribution within 40 miles, by Oct. 2. Specifications, etc., may be obtained from the Manager of the Company.

Bangour (Scotland).—The Edinburgh District Lunacy Board invite tenders for (1) electric wiring and cables, (2) telephone installations, (3) electric bells, required in connection with certain buildings erected and to be erected at Bangour. Tenders to be lodged with Mr. And. Ferrier, clerk, Edinburgh District Lunacy Board, Castle-terrace, Edinburgh, by 28th inst.

India Office, S.W.—The Secretary of State for India in Council is prepared to receive tenders to supply (1) compressed paper blocks ; (2) carriage and wagon wheels and axles ; (3) electrical plant. The conditions of contract may be obtained on application to the Director-General of Stores, India Office, Whitehall, S.W., and tenders are to be delivered at that office by 2 p.m. on 13th inst. for Nos. 1 and 2, and on 20th inst. for No. 3.

Ballinasloe (Ireland).—The Joint Committee of the District Asylum invite tenders for the supply and erection complete, with acid trays, spray arresters, insulators, etc., of a set of accumulators, consisting of 110 cells, having a capacity of not less than 342 ampere-hours, and a maximum discharge rate of not less than 60 amperes. Tenders, addressed to the Resident Medical Superintendent, Ballinasloe Asylum, to be left with Mr. James Young, clerk of asylum, by 17th inst.

Greenwich.—The London County Council invite tenders for the manufacture, delivery, and erection at the tramways electricity generating station at Greenwich of the following plant: two 24in. centrifugal pumps and motors, one 3in. centrifugal pump and motor, two 8in. by 8in. three-throw air-pumps and motors, one 3in. artesian well pump, fixed and rotary strainers, etc. Specifications, etc., may be obtained at the County Hall, Spring-gardens, S.W. Tenders by 10 a.m. on Oct. 4.

London, N.—The Edmonton Urban District Council desire to enter into an arrangement with a company for the exercise of their powers under their provisional order. They are prepared to consider offers based upon certain alternative arrangements, particulars of which are set out in the form of tender. Particulars and form of tender may be obtained at the office of Mr. William Francis Payne, clerk, Town Hall, Edmonton. Tenders must be addressed to the Clerk, and delivered by 12 noon on Sept. 27.

La Rochelle (France).—The Chamber of Commerce will shortly issue tenders for a crane with a lifting power for 30 tons. The beam, or the part which projects over the water or vessel alongside, should be long enough to unload from a point about 26ft. 6in. from the edge of the quay. The height of the distal end above the quay should be 15m. (49·21ft.); the vertical distance between the edge of the quay and that part of the crane directly over it, 8m. (26·4ft.). A locomobile is preferred, but should the conditions be unfavourable for installing such a machine, then a fixed crane would be adopted.

Barking (Essex).—The Urban District Council invite tenders for the construction of light railways as follows: (Contract No. 1 and 1A) rails, fishplates, and bolts; (2 and 2A) permanent way construction); (3 and 3A) overhead line equipment; (4 and 4A) underground feeder cables, etc. Specification may be obtained of Mr. H. Hargreaves, clerk, Public Offices, Barking, Essex, on depositing a cheque for £5. 5s. Applicants to state the contract for which they propose tendering. Tenders to Chairman of the Electricity and Tramways Committee, Council Offices, Barking Town, by 12 noon on Sept. 20.

Shanghai.—The Board of Trade have received through the Foreign Office copy of a telegram from the British commercial agent in Shanghai to the effect that tenders are invited by the municipality of that city for the construction and working of 24 miles of electric tramways on the trolley system, double or single. Conditions of contract, together with plans, etc., may be seen on application to Messrs. Pook and Co., agents for the municipality of Shanghai, 63, Leadenhall-street, E.C., and such modifications of the conditions as may be necessary may be made by tenderers. Tenders must be sent in by March 31, 1905.

Australian Commonwealth.—Tenders will be received at the office of the Deputy Postmaster-General, Hobart (Tasmania). until noon on Sept. 30, 1904, for the supply and delivery at the General Post Office, Hobart, of one multiple metallic branching switchboard. Specifications may be seen at, and tender forms and conditions obtained from, the General Post Offices at Hobart, Melbourne, Sydney, Adelaide, Brisbane, and Perth. Tenders should be endorsed "Tender for Switchboard," and addressed to the Deputy Postmaster-General, Hobart. Tenders may be deposited in the tender-box at the General Post Office, Hobart, or, if sent by post, must be prepaid and registered. Tenderers must state the name of the country in which the switchboard will be manufactured.

London, S.W.—The London County Council require tenders for the manufacture, delivery, and erection at the Council's tramways electricity generating station at Greenwich of two 24in. centrifugal pumps and motors, one 3in. centrifugal pump and motor, two 8in. by 8in. three-throw air-pumps and motors, one 3in artesian well pump, fixed and rotary strainers, etc. Persons desiring to submit tenders may inspect the drawings and obtain the specifications, bills of quantities, form of tender, and other particulars at the County Hall, Spring-gardens, S.W., upon payment to the Cashier to the Council of £2 deposit. Tenders to be addressed to the Clerk of the London County Council, Spring-gardens, S.W., and marked "Tender for Pumping Plant." No tender will be received after 10 a.m. on Oct. 4.

Madrid.—The call for tenders for the service of the electric lighting of Pueblo Nueva del Terrible and Penarroya was without result. The conditions of tender have therefore been modified in certain respects, and a new adjudication is announced to take place on Sept. 18. Tenders are also required for the supply of 25,000 porcelain telegraph insulators, No. 1 of the Spanish type. Tenders, which must be accompanied by a proof that 5 per cent. of the amount has been deposited, will be received at the office of the Direction General of Posts and Telegraphs, No. 10, Carretas, 2° Madrid, up to Sept. 16. The *Gacetas* containing the above notices may be seen by persons interested on application at the Commercial Intelligence Branch of the Board of Trade, 73, Basinghall-street, E.C., any day between 10 a.m. and 5 p.m. (Saturdays, 10 a.m. to 1 p.m.).

RESULTS OF TENDERS.

Hove.—The Council have accepted the tender of the St Helens Cable Company for the supply, delivery, and laying of low-tension cables, conduits, boards, and meters for £7,113. 8s. 8d.

Digitized by Google

Burnley.—The Electricity Committee have accepted the tender of Messrs. Korting Bros., at £145, for supply and erection of pipes and valves required in connection with the extension at the electricity works.

Llandilo.—Tenders for carrying on the electric lighting of the town have been received from Messrs. B. Thomas, whose present tender is about to expire; A. Mayberry, Llanelly; and J. Bowen, Llandrindod.

Ipswich.—The Guardians have received the following tenders for an extension of the electric light installation at the offices:

Collum and Co.	£13	10	0
Hall and Hackblock	17	17	0
Chapman	24	0	0
Tamplin and Makovski	16	16	0
Martin and Newby (accepted)	13	15	6

BUSINESS NOTES.

TRACTION.

Reading.—An electric water-car is in use on the Corporation's tramways.

Liverpool.—The Corporation have adopted a proposal for the use of top covers.

Halifax.—The Corporation have sanctioned the extension of the tramway from Sowerby Bridge to Style Bank at an estimated cost of £4,200.

Wakefield.—The company expect that the Thwaite-gate section, forming a connection with Leeds, will be completed in the course of a few weeks.

Jarrow.—The Town Council have decided to write to the British Electric Traction Company asking them to proceed with the laying of the rails at once.

Pemberton.—The track within the District Council's area is finished, and only awaits the completion of the overhead equipment by the Wigan Corporation.

York.—The proposal to purchase the tramways was considered at a meeting of the Streets and Buildings Committee on Tuesday night, and deferred to a future meeting.

Sunderland.—The Corporation have adopted a recommendation of the Tramways Committee that top covers be used, and that the work be done by the tramway staff.

Colne.—The Corporation have agreed to the Colne and Trawden Light Railway Company's application for an extension of time to complete the Laneshawbridge section.

Bolton.—A proposal that the computation of depreciation on the permanent way should be altered from 8 per cent. on the gross capital to a fixed annual amount of £360 per mile is to be further considered before the next balance-sheet is prepared.

Cheltenham.—The working and extending the light railway, for which Messrs. R. W. Blackwell and Co., Limited, are the contractors, is expected to be put in hand in the course of the next two or three weeks. Operations will commence outside the town, probably at the Charlton Kings end, but almost simultaneously the Leckhampton section will also be proceeded with.

Southport.—The Southport Tramways Company have intimated to the Corporation that they are prepared to sell their undertaking, as they consider that separate ownership militates against efficient working. A part of the company's system, however, extends into Birkdale, where they have leased the lines of the Urban Council, who decline to assent to the proposed change.

Dulverton-Minehead.—In reference to the proposed light railway, the Watchet Urban District Council have received a letter from a London solicitor stating that some clients for whom he is acting are prepared to promote such a scheme. A similar intimation has also been received on behalf of another promoter. The Council have decided to do everything in their power to assist the project.

Derby.—Now that the first contract has been completed, and having regard to the great success of the two routes, which have been opened for the past fortnight, it is expected that at the next meeting of the Corporation the Tramways Committee will bring forward some proposals in relation to the remaining routes, the chief of which are those along Duffield-road, Ashbourne-road, and the Uttoxeter New-road.

Durham.—At the meeting of the Town Council last week a proposal was put forward that the Board of Trade should be communicated with by way of objection to the extension of time desired by the British Electric Traction Company for completing the tramway. Ultimately it was agreed that if the company gave a definite undertaking to proceed with the work, under penalty for non-fulfilment, the Council would raise no objection.

Stockport.—The Corporation having submitted to the Bredbury and Romiley District Council a letter from the County Council as to the conditions upon which the last-named were prepared to assent to the doubling of the tramline in London-road, Hazel Grove, and to the working of the same by electric traction, the District Council have decided to acquiesce in the conditions, except upon one or two minor points. The Corporation have authorised a sub-committee to continue negotiations for the purchase of the company's system.

Aston.—Within the next few days electric trams will, it is expected, be running between Birmingham and the Holte Hotel, Aston. A delay has occurred in the laying of the rails into the depôt in Witton-lane, and consequently the cars cannot be run into that place. In the circumstances, the Aston Corporation will make an arrangement with Birmingham either to store the Aston cars at Miller-street or to work their own cars to the Holte Hotel for about three weeks, by which time the connection with the depôt will have been finished.

Yarmouth.—The Board of Trade has provisionally approved the extension from Blackfriars-road to Queen's-road. Preliminary proceedings have been taken for the acquisition of the Southtown and Gorleston tramways. The surveyor stated that the cost of constructing electric tramways from Southtown Bridge through Gorleston, including car-shed and 10 cars, would be £46,762, to which must be added the cost of purchasing the present undertaking. This scheme will be brought before the whole Council at a meeting on the 30th inst.

Torquay.—The Dolter Company having written asking the Council to state an approximate date when they would be ready to supply the company with electric current, the town clerk was instructed to reply that if the secretary would give some idea when the company would require the current, the Council would use their best endeavours to supply it. The company's reply to this was that they would naturally like to make a start as early as possible, but felt that it would be useless to do so until they could get some definite information as to when the supply of electric energy would be available. The Town Council have written suggesting a conference.

Bury.—Through running to Whitefield was instituted last week. After a successful trial trip representatives of the different authorities met at the Whitefield Council chamber, where courtesies were exchanged. The question of fares remains in abeyance pending the completion of arrangements with Salford. Communication is now opened up between Bury and Manchester, but at present passengers have to change at Whitefield. Through running will, however, probably take place before long. The Tollington section will probably be ready for inspection in a day or two. The construction of the Radcliffe-road section has been commenced. The Heywood Town Council have intimated that they will submit further proposals.

Plymouth.—A lengthy discussion ensued at the meeting of the Town Council in regard to track renewals, which, it is stated, will be necessary before long. The question of forming a depreciation fund was alluded to, and the Town Clerk expressed the opinion that if the Council were in favour of such a step it would be well to get direct authority for the purpose, as he doubted whether the provisions of the Legislature sanctioned such a course. Mr. Everson, the tramway manager, assured the meeting that the overhead equipment, about which misgivings had been uttered, was inspected weekly, and was in splendid condition. It was stated that certain formalities lay in the way of the immediate construction of the Garden-street extension.

Bradford.—Considerable progress has been made with the extensions of the tramways from Undercliffe to Greengates and from Allerton towards Sandy-lane. The former line will probably be opened in a week or two. The short length of about a third of a mile which is being added to the Allerton line is expected to be ready in about six weeks. A petition is being extensively signed at Oakenshaw praying the Corporation to extend the tramway from Odsal Top to the city boundary in the direction of Cleckheaton. It is pointed out that the locality has not the same facilities in this respect as almost every other part of the city, and it is suggested that if an extension were made as suggested the Cleckheaton and Dewsbury line might eventually be continued to Oakenshaw.

Newcastle.—The latest traffic returns show that in the five weeks ending Sept. 3 there were 4,085,759 passengers, as against 3 807,284 in the corresponding period of last year. The mileage run was 420,248, as compared with 387,615, and the takings were £18,369, as against £17,596. The number of cars in use was 112, as compared with 104, and the mileage works out at 10·49d. per car mile, against 10·89 in the same period of 12 months ago. Alderman Ellis remarked that it was the most unfavourable report yet presented. The Tramways Committee have decided to supply to every member of the Corporation the detailed information in regard to the depreciation question asked for by a councillor a few weeks back. It has also been decided to build no more cars at present. Owing to the through running arrangement, the Corporation is said to be overstocked.

Perth.—At a meeting of the Tramway Reconstruction Committee last week the report by the engineers, Messrs. Kincaid, Manville, Waller, and Dawson, on the offers for the reconstruction of the tramways, was submitted to the meeting. Mr. Dawson gave explanations regarding the various contracts, and was questioned by members of the committee on various points, especially on the proposal to introduce petrol cars. Treasurer Lawrie maintained that the petrol car had been a success in Perth, and it was a very much lighter car than the cars which Mr. Dawson proposed to put on the route. In reply to Treasurer Lawrie, Mr. Dawson condemned the introduction of the petrol car at the present time, contending that a 10 minutes' car service could only be obtained by electricity, but petrol 'buses would be suitable for an hourly service. Were they to introduce petrol or electricity, the Town Council would require to relay the rails, and this being so, the introduction of the former would mean a considerable expenditure, whereas if they decided on electricity, the relaying of the rails would be about half of the total cost. Again, the petrol car was too light, and the engine which they had been using was not of sufficient horse-power, and the engine which the company proposed to introduce would still be insufficient, and with such a heavy engine after five months' trial the car would be destroyed. It is understood that the Committee will hold another meeting at an early date to make recommendations to the Council.

Rochdale.—At last week's meeting of the Tramways Committee it was agreed to accept Heywood's proposal to supply power for the running of trams in their borough. Bury, it is thought, are likely to consent to this. New alternative terms are to be submitted to Hey-

Digitized by Google

wood, but in each case the demand of the Heywood Corporation to supply current for the cars as they run through their district is acceded to by Rochdale. One set of proposals provides that Rochdale shall construct and maintain the lines on their side of Heywood market place, and also put up the overhead equipment; that Heywood shall pay their share of the purchase price of the old undertaking; and that Rochdale shall have possession of the new system for 21 years, at the end of which time it shall be handed over to Heywood. The other proposal involves reconstruction by Rochdale, who will pay twenty-one-thirtieths of the purchase price of that part of the company's system in Heywood, and pay it at the rate of one-thirtieth per year. At the end of 21 years Heywood will, under this scheme, take over the property at a valuation. Arrangements have now been completed with the Whitworth District Council for the electric cars from Rochdale to run to Ending, a couple of hundred yards beyond the borough boundary. The reconstruction of this short length will be undertaken at the beginning of next week. The fixing of the overhead equipment on the Royton section has now been carried nearly the whole distance to Summit, and efforts are to be made to get the Milnrow-road section ready for running at an early date. The laying of the electric cables is being pushed forward rapidly. A later report states that the impression that Rochdale has acceded to Heywood's demand that the latter should supply power for the cars after they pass the Heywood boundary is incorrect, Rochdale being desirous of supplying the energy for running the trams through to the Market-place. At the meeting of the Electricity Committee last week there was some discussion as to the supply of current now available for tramway traction. Mr. Atchison, the electrical engineer, stated that the existing plant was capable of producing the power sufficient to run 27 cars, and that when the Tramway Committee was ready with ducts, cables, and overhead equipment on the Healey and Milnrow-road sections there would be no difficulty in regard to the power.

Handsworth.—The District Council evidently intend to stand upon their rights. The South Staffordshire Company, it will be remembered, has secured the concession for working the line from Handsworth to West Bromwich. The lease from the former authority has not, however, been executed at present. With a view, it was reported, to benefiting by the big football match on Saturday, the company set to work during the small hours to connect the wire, so that their cars could continue the journey after passing the West Bromwich boundary. But, alas! the best-laid schemes, etc. No sooner had a car entered upon the Handsworth section than the Council's officials appeared upon the scene and protested. Not only this, but, on finding the company persistent, they backed their arguments by placing a heavy steam-roller across the line at the border. To make assurance doubly sure, the engineer proceed to fix up an arrangement by which the current was short-circuited and the connection between the two portions of line was broken in three places. The company could not combat such tactics, and so they were unable to accomplish their purpose. Some correspondence on the subject has since passed between the parties. The Handsworth Council had previously intimated to the company that no cars must be run until the Board of Trade had inspected the tramways and the lease completed. The lines had not been passed by the Council's engineers because the work could not be tested until certain differences between the company and West Bromwich had been settled, West Bromwich having declined to allow any temporary or other connection to be made. The Council threatened an application for an injunction unless the company undertook not to repeat the attempt without special consent. The company has replied that as the junction of the electrical equipment is outside the boundary of the Council, it was not possible for the connecting up to be carried out by employés of the Council and that the only car run was for test purposes, and as a preliminary to the application for the Board of Trade inspection. The company had no intention of running a service of cars for public traffic until permission had been obtained from the Board of Trade. The company demand that the Council shall make good the severance of the equipment, but express their desire to co-operate with a view to the opening of the complete service at an early date. The dispute between the West Bromwich Corporation and the company has, it appears, just been settled. Terms were arranged between representatives of the Corporation and the company at a private conference, and the lease has now been signed, the company handing to the Corporation a cheque for several thousand pounds, the amount due for rent and electricity charges up to June 30 last. The agreement is said to be for five years certain.

LIGHTING AND GENERAL.

Rhyl.—Sanction has been obtained to borrow £2,610 for electric lighting purposes.

Motherwell.—The town was in partial darkness on Saturday owing to the bursting of a cable in the power-house.

Walsall.—The Town Council have decided to reduce the charge for electricity to a uniform one of 4d. per unit.

Swinton and Pendlebury.—Negotiations are proceeding with the Lancashire Electric Power Company for electric lighting.

Longton.—The output of electricity during August was 4,094 units, being an increase as compared with last year of 23 per cent.

Shalimar.—The Government of India have approved of the expenditure of half a lakh of rupees for the supply of electric transporters at Shalimar.

Caerphilly.—A committee has been appointed to consider the appointment of an electrical engineer to superintend the Council's installation.

Aspull.—The Board of Trade have agreed to defer consideration of the question of revoking the electric lighting order for one year from the 22nd inst.

Andover.—The Town Council intend to apply for a provisional electric lighting order, which they do not intend to work themselves, but to transfer.

Bury.—The electrical engineer in his last report states that during the past month applications have been received for 107 8-c.p. lamps and a 5-h.p. motor.

Birkenhead.—Sanction has been obtained to the borrowing of £20,000 for the Upton and Prenton supply extension without an enquiry being held.

Maidenhead.—An enquiry will be held shortly into the application by the Town Council for sanction to borrow a further sum of £3,000 for electricity purposes.

Bexhill.—The Electric Light Committee are about to extend the electricity cable to supply houses on the Woodsgate Park Estate at an estimated cost of £170.

Bristol.—An enquiry is to be held to-day into the Council's application for sanction to borrow £126,000 for the Avonmouth and Temple Back station extensions.

Sale of Plant.—The Corporation of Leicester are prepared to receive offers for tramway temporary track, with turn-outs, etc. Particulars in advertisement columns.

Transvaal.—The *Transvaal Government Gazette* of Aug. 12 contains the text of an ordinance sanctioning the expenditure of £13,000 on telephone materials.

Bredbury and Romiley.—The Urban District Council are considering a report by Mr. Charles Richardson, of Romiley, setting forth alternative schemes for lighting the compulsory area.

Govan.—Application is to be made to the Secretary for Scotland for increased borrowing powers to the extent of £47,000, which sum is to embrace all extensions of the electricity plant up to 1906-7.

Keswick.—The Urban District Council have accepted the terms of the Windermere and District Electricity Supply Company for lighting three arc lamps. We understand that the price to be paid for 2,000 c.p. is £40.

Twickenham.—The Council have agreed not to sanction the erection of the proposed cooling tower at the electricity station, or enter into any agreement with reference thereto, unless the consent of the owners of the adjoining property is first obtained.

Stock Exchange.—Application has been made to the Stock Exchange Committee to grant a quotation to the United River Plate Telephone Company's further issue of 12,000 ordinary shares of £5 each, fully and partly paid, Nos. 58,001 to 70,000.

Sunderland.—The Town Council have agreed that for the purpose of meeting the increased demand for power at Messrs. Doxford's shipyard, alterations and extensions of plant should be made at the Hylton-road electric supply station at an estimated cost of £3,000.

Lien Registered.—The Fladbury Electric Light and Power Company had a lien registered on Sept. 3 for £150 5 per cent. debentures, part of £300; amount previously issued, £150; no trustees; charged on the undertaking and all the property and assets, including the uncalled capital.

Lowestoft.—There are now connected to the mains 536 consumers, representing 27,099 8-c.p. lamps. During the last month two new consumers were connected, representing 64 8-c.p. lamps. The engineer has fixed two temporary cables under the harbour at a cost of £58. 10s., which are working satisfactorily.

A Library of Technology.—Particulars will be found in another column of an international library of technology, of which 45 volumes are now ready. They are sold in any combination of five or more volumes by the International Text-Book Company (British agency), 57-58, Chancery-lane, London, W.C.

Perth.—The last report of Mr. Lambert, the electrical engineer, shows that the number of units generated during August was 36,428, an increase of 2,402 units in the month. The lamps connected were equivalent to 150, making the number connected up to date 26,982. The coal used per unit of electricity generated was 7·81lb.

British Engines for New York.—The *Daily News* understands, from an official source, that the General Electric Company, of Schenectady, New York, have placed an initial order with the Wolseley Tool and Motor Company, of Birmingham, for one of their powerful six-cylinder petrol engines, to develop, at normal revolutions, 140 b.h.p.

Hove.—The Council have now consented to the Brighton Corporation carrying telephone wires over the town hall provided they entered into an agreement to remove the wires on receiving three calendar months' previous notice, and to make good any damage done to the premises caused by or arising out of the wires or the carrying over or removal of the same.

Dudley.—The gross profit in connection with the electricity supply account for last year is considerably more than for the previous year, being £5,012, on which there is a net profit of £655. The capital expenditure has been £70,000, and a gross profit of £5,012 gives a return of 5 per cent., which would absorb £3,500, and leave a balance of £1,500 to put to a depreciation fund.

Pudsey.—An enquiry has been held into an application for sanction to borrow £5,000 for electric lighting. Of this sum £3,000 is wanted for cable-laying and £2,000 for extensions when required. Current will be obtained in bulk from the Yorkshire Electric Power Company, and the Council will erect a transforming station on a suitable central site recently acquired for street improvement.

Radcliffe.—The generating station for the Lancashire Electric Power Company is rapidly approaching completion, and negotiations for the supply of energy in bulk are far advanced with Rawtenstall, Bacup, Haslingden, Swinton and Pendlebury, and various other local

Digitized by Google

authorities. The supply of electrical energy in bulk to collieries promises to be a feature in the working of the company.

Croydon.—A pamphlet has just been issued by the electricity department of the Corporation. The Electricity Committee now charge 2½d. per unit to consumers who require power at all hours, and 1½d. per unit to those who do not require power between dusk and 11 o'clock. The advantages of this system, the methods and machinery used for producing the current at the Croydon stations, etc., are detailed in the pamphlet.

Board of Trade Regulations.—A special meeting of the Power Bills Parliamentary Committee of the London Chamber of Commerce will be held at Oxford-court, Cannon-street, E.C., on Sept. 21, at 3 p.m., to consider the draft regulations issued by the Board of Trade for securing the safety of the public and for ensuring a proper and sufficient supply of electrical energy, to the contents of which we have already referred in previous issues.

Reading.—On Friday the new electric water-cart, which has been built for the Corporation by Messrs. Dick, Kerr, and Co., of Preston, was removed from the Reading Station goods yard and placed on the tramrails, fitted all ready for the application of electric power, under the superintendence of Mr. Hodgson (Messrs. Dick, Kerr, and Co.'s representative). The car has since been used to water the permanent way and sides of the roads abutting on it.

Portsmouth Telephones.—The municipal telephone system has now been extended to Rowland's Castle. The price to country subscribers is exactly the same as that charged to those of the town. The charge at the Corporation call offices is 1d., and the municipal system now covers Portsmouth, Gosport, Cosham, Portchester, Fareham, Pubrook, Waterlooville, Havant, Emsworth, and Rowland's Castle, the total number of subscribers being over 1,800.

Electrical Testing.—The Westminster Electrical Testing Laboratory, York-street, Westminster, have just issued a neat booklet containing their scale of fees. The object of the laboratory is to assist manufacturers, contractors, consulting and resident engineers in the carrying out of tests which they are unable to undertake for themselves from either lack of suitable apparatus or a sufficiently skilled staff. Experimental and research work is also undertaken on behalf of inventors and others.

Dewsbury.—The electrical engineer, in his report upon the recent breakdown of the cables, states that for a long time Dewsbury had had remarkable immunity from accidents of this nature, and a continuous supply of energy. The fault on this occasion had arisen from the smaller mains in the distributing boxes. The bulk of the difficulty has been got over, and Mr. Campion has advised certain measures which would obviate a recurrence of this trouble, and enable him to locate the faults more readily when occasion arose.

Elland.—The last report of the electrical engineer states that during the five weeks ending July 31 the engines ran a total of 144½ hours, generating 6,131 units, and that the output was 2,084 units. The total output from July 1 to 31 was 1,984 units, an increase of 300 on the previous month. At the end of this period the total number of consumers was 69, and the total number of 8-c.p. lamps connected 4,156. During the five weeks ending July 31 the destructor ran 299½ hours, detroying 265 loads of refuse and 150 loads of sludge.

Aberdeen.—On Monday the Council asked the Lighting Committee to consider the advisability of a more general extension throughout the city of the improved street-lighting recently adopted by the Council for the tramway routes, and to report. It was explained that at the present time the committee had incandescent lights throughout that part of the city, and the result of that had been that there had been a constant demand for improved lighting in other parts. If that were generally done, it would put an end to the present patchwork system.

Electricity in Collieries.—Messrs. Bolckow, Vaughan, and Co. are extending the utilisation of electrical energy for motive and lighting purposes to their Shildon Lodge pit. Arrangements have been completed for the putting down of cables to convey the power from the Auckland Park Colliery pit to Shildon, two miles distant. New engines will be fixed, and from the power-house at Auckland Park energy will be derived for haulage and lighting purposes at Shildon Lodge. At Shildon, also, cables are being put down for the supply of electric light for public use.

Electrical Ore Finding.—The operations on the Barrow Hæmatite Steel Company's property, under an agreement whereby the Electrical Ore-Finding Company will receive royalties on the ore raised, have been successful in the location of hematite ore. The instruments having located certain spots that contained hematite in ground that had not been previously worked in any way whatever, bores were put down by the steel company, and hematite ore has been struck at a depth of 88ft.—*i.e.*, within a few feet of the depth previously indicated by the Ore-Finding Company's operators.

Newport (Mon.).—The borough electrical engineer has reported that Messrs. Cordes (Dos Works) have been making enquiries as to obtaining a supply of electrical energy for power purposes at their works, and they estimate that they will require 1,400,000 units per annum. They, however, suggest that they should be supplied at less than the scale rate for power adopted by the Corporation. The matter having been considered, the committee resolved that the company be offered the supply of current required by them at the scale rate, which the committee consider is the lowest they can charge and obtain some remuneration.

New Company.—The Simplex Arc Lamp Syndicate, Limited, has been registered with a capital of £16,000. Objects: to adopt agreements (1) with A. Heller, (2) with F. W. Stevens, and (3) with C. J. Scott, and to carry on the business of manufacturers of and dealers in arc and other lamps, brackets, globes, films, shades, glasses, burners, meters, galvanometers, ammeters, voltmeters, carbons, cut-outs, switches, motors, batteries, stoves, turbines, pipes, wires, and all appliances and things used in connection with electricity or any other illuminant or generator of light, heat, or power; suppliers of electricity and other light; electrical and general engineers, etc.

Ayr.—The annual report of the burgh electrical engineer, Mr. Roland Marshall, states that the units generated reached a total of 1,119,629, an increase as compared with the previous year of 102,593 units. The prices charged for current were: private lighting, 5d.; public lighting, 2d.; traction, 1·5d. and 1d.; power, 2d; and the revenue was as follows: private lighting, £5,627; public lighting, £3,590; traction, £1,753; other sources, £286—being a total income of £11,257. The expenditure, including £4,822 interest and sinking fund, was £10,629, leaving a net surplus of £627, or £326 in excess of last year. Sanction has been obtained to a loan of £15,000.

East Barnet Valley.—The Urban District Council are considering an offer from the National Electric Construction Company for carrying out the complete central-station equipment. Including the extensions to Hadley Wood, the cost will be £15,500. This includes a sum of £1,250 for buildings, £250 for land (half an acre), and a provisional sum of £500 for street-lighting. The plant will consist of gas producer and gas-engines with direct-coupled machines, storage battery, balancer and boosters, switchboard, mains, and all the necessary accessories for a complete equipment. The engines will be capable of dealing with a load of 60 kw., and the battery will consist of 256 cells, having a capacity of 80 amperes for five hours.

Dundee.—The partial breakdown in the electricity supply on Monday night was, it is stated, caused by a service cable giving way. This occasioned a heavy current to flow through the copper strip feeders, which were already weak, and they, too, collapsed. The weakness of the copper strip and many of the services and boxes put in about two or four years ago was brought to the notice of the Council by the engineer some months ago. The current had to reach the centre of the city by way of the outlying cable feeders at the west, north, and east ends of the city. This threw very heavy work on to these feeders and the Perth-road distributor, but they might have stood the strain if the latter had not been damaged where it runs in front of the premises recently erected.

St. Marylebone.—The Borough Council intend to apply to the London County Council for approval to an alteration of the standard pressure of supply to consumers in the area of supply comprised in their order. At the present time current is supplied at pressures varying from 50 to 200 volts on the alternating and continuous current systems. It is now desired to alter this into a continuous-current supply at 240 volts on the low-tension system. The London County Council have sanctioned the borrowing for 42 years by the Marylebone Borough Council of £340,045 for electric lighting works, subject to the latter body's providing out of a sinking fund, or from maintenance account, for all renewals and replacements during the currency of the loan of plant, machinery, and works, and a loan for 38 years of £48,545, the estimated cost of bringing existing plant into working order, and a loan for 10 years of £44,850 for meters or alterations to existing meters consequent on change of pressure. These loans are in addition to the loan of £1,212,000 already incurred to pay the Metropolitan Electric Supply Company for their Marylebone property and goodwill under arbitration award.

Southwark.—At the Borough Council on Wednesday evening, on the first meeting after the recess, some remarkable opinions on electrical engineers were expressed by Alderman Boyd. It will be remembered that the services of the late electrical engineer to Southwark Borough Council—Mr. Blaikie—were dispensed with by this Borough Council in a manner which caused much comment in the electrical world. On Wednesday evening the Electric Light Committee recommended that advertisements be issued for a chief engineer and manager of the electric light undertaking at a salary of £300 per annum, rising by annual increments of £20 to a maximum of £400 per annum. A long discussion arose on this recommendation. Councillor Chell moved that the matter be referred back for further consideration. He argued that they did not want an electrical engineer to manage the concern, but a commercial man who would go out and canvass for customers, whilst a mechanical man should manage the electric light station. Alderman Boyd warmly supported the proposition of Councillor Chell. They did not want an electrical engineer, he said, with a lot of letters after his name, but a good business man to manage the concern outside the station and a smart mechanical engineer to manage the station itself. Properly speaking, he said, there was no such thing as an electrical engineer. Any person of ordinary intelligence could read up in a month all that an electrical engineer knew. There was nothing in it. It was all a lot of theory. What they wanted was a good mechanic to supervise the station. Councillor Attenborough said he did not think it was any good for the Council to issue advertisements for a qualified electrical engineer. The Council had treated the late chief of their electric lighting department so disgracefully, that no member of the Institution of Electrical Engineers would be likely to apply for a post under such a council. Councillor Hill advised the representatives of St. George's, Christchurch, and St. Saviour's, in which parishes the Newington electric lighting order does not run, not to take any part in the voting, but to leave Newington to "stew in its own juice." After a long debate, the committee's recommendation to advertise for a chief engineer and manager was carried by a large majority.

Colchester.—Electric lights are to be substituted for 13 oil lamps in Mile End-road. The Electric Light Committee in their last report give the output of electricity in July as 23,174 units, number of consumers as 515, and the number of 8-c.p. lamps connected as 26,505. It is proposed to charge the Tramways Committee for the first year of working 2½d. per unit, and 10s. 6d. a week for making the daily tests required by the Board of Trade. The Lighting Committee has been informed that if the number of public electrically lighted lamps can

Digitized by Google

be increased to 400 equivalent half-ampere lamps, this committee will be prepared to made a charge of 2½d. per unit till the ending of the financial year.

Devonport.—The demand for current for motive power and lighting has increased 50 per cent. in the last 12 months, and as more favourable terms have recently been offered to consumers there is a prospect of the increase continuing. The Electric Power Committee consider that the need for extending the plant is urgent, and the chairman (Mr. H. Banbury) and the electrical engineer (Mr. J. W. Spark) have been deputed to inspect a number of engines and report to the committee, with a view to one being purchased and laid down in time to augment the supply for the coming winter. Although the necessity for extending the plant has arisen earlier than was expected when the works were built, it was anticipated, and the bed for the new engine is already provided.

London Gazette.—An adjudication order has been made *re* Henry Bock Binko, electrical engineer, carrying on business at 34, Leadenhall-street, E.C., and residing at 4, Highbury-crescent, Highbury, Middlesex. The partnership between George Frederick Matthews and Aubrey Hunter Spalton, carrying on business as electrical and mechanical engineers at 64, and 80, West-street, Sheffield, has been dissolved by mutual consent; also that between William James and William S'. Just Clarke, carrying on business as electrical engineers and instrument makers at 174, Pentonville-road, Clerkenwell, E.C., and 16, Camden-road, N.W., under the style of "W. S. Clarke and Co." Mr. William Henry Platts, 1, Oxford-row, Leeds, chartered accountant, has been appointed trustee in the estate of the Yorkshire Motorcar and Electrical Engineering Company, carried on at 101, Kirkstall-road, Leeds.

Barrow.—The Council at their last meeting discussed at length a petition from shopkeepers who objected to paying 6d. per unit for electricity while householders were charged 4½d. Finally it was decided to reply that they could not see their way to reduce the charge at present. It was pointed out that the system of charging had been based on the principle of charging each consumer in proportion to what it costs to supply him with current, and that this cost is much greater in the case of shops than in that of private houses; that their letter assumed that the tradesmen paid 6d. per unit, whereas the average price for the last year worked out at about 5½d., and that the committee much regretted they were unable to make a general reduction last March, but were confident, with the improved state of things now existing at the works, to be able to reduce the hours for which the maximum price was charged, from 1½ hours to one hour.

Macclesfield.—At the last Town Council meeting, the town clerk read notices from the Empire Electric Light and Power Company, London, Messrs. Foote and Milne, London, and Mr. G. Vaughan Fowler, Warwick, of their intention to apply for a provisional order to supply electricity within the borough. There was also a letter from the Industrial Engineering Company, of Newton, near Hyde, submitting a generalised arrangement of their scheme for lighting the borough, and enquiring, in the event of the Corporation deciding not to go in for a scheme of their own, if they would give the company the option of purchasing the provisional order, or their help in securing the same from the Local Government Board. Finally, the chairman was asked to procure further details of his scheme for a 200-kw. plant with feeders, distributing mains, etc., at a cost of about £12,000, excluding buildings and site. The Chairman, Messrs. Councillors Brown, Cross, Clayton, and Isherwood were appointed a sub-committee to further consider the route along which the cables shall be laid in the first instance.

Clydebank.—Recently the Clyde Valley Electrical Power Company enquired whether the Council would take a supply of electricity for public purposes, and explained that, as the alternating current at 50 cycles per second would be more suitable for the burgh and district, they were prepared to bear the expense of altering the wiring in the municipal buildings from the direct-current system to the alternating-current. The Electric Lighting Committee at first agreed to adhere to the direct-current system, as stipulated in the agreement with the Clyde Valley Company, but to allow a rotary transformer to be placed within the buildings alongside the present dynamos, provided the company would take over the dynamos at a valuation. The company afterwards suggested the introduction of concentric wires, which could be drawn through the present tubes without breaking out any of the plaster or woodwork of the building. The committee then agreed to allow the alteration of the wiring of the buildings on certain conditions, one of which was that the company undertake to have the new current installed in the buildings not later than Feb. 15 next, so as to enable the Council to give delivery of their machinery and plant to a purchaser on that date. This course has been agreed to by the Council.

Wisbech.—An enquiry has been held by Colonel Meade-King into the application of the Town Council for sanction to borrow £35,000 for purposes of establishing an electric lighting undertaking. As already noted, a provisional agreement has been entered into between the Council and the National Electrical Construction Company, under which the latter will carry out all the work in connection with the scheme and run the undertaking themselves for at least a period of years, and under which the money for the scheme is to be borrowed by the Council and repaid by the contractors. The Corporation was represented by Mr. J. Ellis Griffiths, M.P. (instructed by the town clerk, Mr. Geo. Carrick). The ratepayers opposing the scheme were represented by Mr. Arthur H. Poyser (instructed by Mr. T. R. Dawbarn), and Mr. H. St. John Raikes (instructed by Mr. Robert Dawbarn) opposed the scheme on behalf of the Wisbech Lighting Company. The electrical engineers employed by the Corporation, Messrs. Hammond and Sons, were represented by Mr. Spencer Hawes, whilst the managing secretary of the National Electrical Construction Company, Mr. W. B. Cownie, was also present. Amongst those who gave evidence were the Mayor (Mr. H. C. Elgood), the chairman of the Electric Lighting Committee (Mr. A. Southwell), the borough surveyor (Mr. A. H. Plowright), and the manager of the lighting company (Mr. J. G. Hawkins).

Sheffield.—The electric supply department have issued a large illustrated postcard, in which the general manager and engineer (Mr. S. E. Fedden) points out that it is in the consumers' interests to overhaul their incandescent lamps from time to time and remove any which may have become blackened with use, resulting in loss of light and efficiency. He says: "To secure the greatest economy in electric lighting only first-class lamps should be used, the small extra cost over inferior grade being saved many times over during the life of the lamp by the reduced consumption of energy per candle-power. For example, a low-class 16-c.p. lamp, costing, say, 8d., may consume one unit in 12 hours, whereas lamps of the same candle-power such as are sold at about 1s. each, will frequently burn for 16 hours with the same consumption of energy, in addition to which the good lamps need not be changed so frequently as the poor ones. Assuming, however, their life to be equal, say 650 hours, the relative cost will be approximately as follows: Low-grade 16-c.p. lamps—first cost, 8d.; energy consumed at five watts per candle-power = 52 units at 4d., 17s. 4d.—total cost, 18s. High-grade 16-c.p. lamps—first cost, 1s.; energy consumed at four watts per candle-power = 41·6 units at 4d., 13s. 10½d.—total cost, 14s. 10½d., or, approximately, a saving of 15 per cent. in favour of the high-grade lamp. Attention to these details at the commencement of the winter season will secure a maximum of comfort and satisfaction, and assist in economising energy and reducing consumers' accounts."

Battersea.—The London County Council have consented to the erection of the coal-conveying plant at the central electric generating station. Various mains are to be extended at an estimated cost of £119, and also additional cable is to be provided in stoneware casing already laid at an estimated cost of £317. The committee have been considering the charges made for the supply of electrical energy to, and maintenance of, arc lamps within the borough. They state that they have ascertained that the charges made by other metropolitan borough councils supplying electricity are as follows: Bermondsey, 3d. per unit (about £25 per lamp per annum); Fulham, £25 per lamp per annum; Hackney, £18 per lamp per annum; Hammersmith, £22. 10s. per lamp per annum; Hampstead, £28 per lamp per annum (500-watt arc lamp); Shoreditch, £31 per lamp per annum (nearly); Southwark, £28. 7s. per lamp per annum (3½d. per unit); St. Pancras, 3d. per unit (about £25 per lamp per annum). The electrical engineer has prepared a report showing the cost to the electricity department of the street-lighting for the year 1903 4 and the estimated cost for the year 1904-5. Taking into consideration the charges for generation and distribution of electricity, rents, rates and taxes, management expenses, and special charges during the year 1903-4, a loss of about £779 has been incurred. Having regard to the whole of the circumstances, the committee recommend that the charge for the supply of electrical energy to, and maintenance of, arc lamps be increased from £16 to £18 per lamp per annum. There are at the present time 356 arc lamps fixed in the borough, and in the event of the recommendation of the committee being adopted, an increase of £712 will have to be provided for in the estimates for the accounts of the Council as lighting authority, but a corresponding increase in the revenue in the accounts of the electrical undertakings will be effected.

Salford.—An enquiry has been held into an application by the Town Council for sanction to borrow £5,000 for purposes of electric lighting for the district included in the Prestwich electric lighting order of 1900. Mr. J. Purrett, deputy electrical engineer, said in his evidence that the money was required for the purpose of enabling a supply of electricity to be given in the district of Prestwich, covering an area of 2,435 acres, with a population of 12,839. With reference to the system of supply, the single-phase alternating-current system was to be adopted similar in all respects to the system of supply which had been in use in the district of Higher Broughton, Salford, for the past eight years. Duplicate high-tension cables conveying electricity at 3,000 volts pressure would be laid to a sub-station situated centrally in the area, a branch being taken off one of the cables in order to supply Hilton-lane. From the sub-station low-tension cables would be laid. Transformers would be used in the sub-station to transform the pressure from 3,000 volts to 200 volts, and this pressure would be supplied wherever low-tension cables were laid. A pilot cable for indicating the pressure of supply at the sub-station would be laid with the other cables. High-tension cables would also be laid down Rectory-lane and Whittaker-lane, and persons requiring a supply of electricity in these two roads, and also in those parts where low-tension cables were not laid, would be provided with individual transformers for transforming the pressure down to 200 volts. In these cases the high-tension alternating current would be taken direct into the houses; in every case the transformers would be enclosed in a cast-iron box. No cables had been provided for in Bury Old-road by agreement with the Prestwich Urban District Council, the arrangement being that should any applications be made from this road the cables were then to be laid. Were cables required to be laid the capital expenditure would be £626, upon which an adequate return could not be expected at present. Lead-covered and concentric cables would be used, with the exception of the pilot cable, which would be twin lead covered. The high-tension cables and the pilot cable would be drawn into pipes, but the low-tension cables would be armoured and laid direct in the ground, the soil being of a satisfactory nature. A sum of £962 had been included for service cables, meters, etc., necessary for connecting up consumers. Allowing £20 per consumer approximately, 50 consumers would be connected with this expenditure. The current to be used in the area would be conveyed by cables already in use from the Frederick-road works to the boundary of the borough of Salford. Those cables would then be connected to the

Digitized by Google

cables proposed to be purchased under this loan. The transformers which would be used in the area were already in the possession of the Salford Corporation, having been used in Salford prior to the system in the centre of the town being changed from alternating to direct current. No new expenditure under this heading would, therefore, be required for some time. They had sufficient power at the Frederick-road station to supply this extra demand.

Londonderry.—The Corporation obtained a provisional order in 1891, and in 1894 the public lighting installation was commenced. Specifications and plans for private lighting and power purposes were prepared jointly by Messrs. Preece and Cardew and Mr. Macrory in 1901, and contracts entered into in May, 1903, amounting to about £20,000. A contract was afterwards accepted for the new buildings for £5,500. Owing to the site of the station being reclaimed land, great care had to be taken in putting in foundations for the new buildings, which are sunk to hard ground, in some cases 14ft. deep. A foundation of cement concrete, from 2ft. to 4ft. deep by 6ft. wide, has been provided under all walls. The engine-house extension is 75ft. long, 50ft. wide, and about 40ft. high, and is finished with open iron roof and lantern light. The switchboard platform occupies one side, at a level of 5ft. above the floor, and is approached by a double flight of cast-iron steps, and protected by polished steel rails and standards. The floors of platform and engine-house have been laid with encaustic tiling. The new boiler-house is parallel to the engine-house, and is 90ft. long, 48ft. wide, and 30ft. high, with open iron roof and louvre ventilation along the whole length of ridge. There are at present five boilers and space for two additional ones. Between the boiler-house and quay a store provides room for 1,000 to 1,500 tons of coal. At the end of boiler-house a new pump-house has been erected, with a large tank overhead providing water supply to the condensers. The supply for this tank is drawn from the river by two electric motor-driven pumps, while the old tank is used for supply to steam-boilers. The whole of the buildings, etc., including batteries and test-rooms, stores, etc., have been carried out by Mr. R. Colhoun, of Londonderry. The sub-contractors were Messrs. Wm. Nelson and Alexander Brown and Co. for decoration and iron stairs and railing respectively. The plans and specification for the works were prepared by Mr. Daniel Conroy, architect, under whose superintendence they were executed, Mr. W. M'Elwee acting as clerk of works on behalf of the Corporation. The total outlay on buildings, etc., is about £7,175. The boilers, pumps, condensing plant, and pipe connections have been supplied by Messrs. Victor Coates and Co., of Belfast. There are three new Lancashire boilers, each 7ft. 6in. diameter by 26ft. long, suitable for a working pressure of 125lb. per square inch, constructed throughout of Siemens-Martin mild steel. The feed pumps are of the Weir vertical direct-acting type in duplicates, each capable of delivering 2,500 gallons of water per hour, and are placed in the pump room, which also contains two Pulsometer centrifugal pumps coupled direct to Brush shunt-wound continuous-current motors provided with no-load and overload automatic releases. There are three condensers of the ejector type, by Messrs. Korting Bros. The contract for the generating plant was carried out by the British Thomson-Houston Company, of Rugby, who built the electrical apparatus and sub-contracted the engines to Messrs. W. H. Allan and Sons, of Bedford. There are four direct-coupled steam sets, two capable of developing 250 kw. each. These dynamos are shunt-wound six-pole machines. The compound engines which drive them are of 375 i.h.p., each with high-pressure cylinders of 14½in. and low-pressure cylinders of 24in. diameter and having a stroke of 10in. The two smaller sets are six-pole 100-kw. machines, compound wound with a view to being eventually used to supply power to the future electric tramways. The British Thomson-Houston Company also supplied the balancer-booster set. The battery was manufactured by the Electrical Power Storage Company, of 4, Great Winchester-street, London, E.C., and consists of 268 cells. The contractors for the switchboard were Messrs. Cox-Walkers, of Darlington and Edinburgh, who have also carried out the cable work connecting the machines with the board through the various energy-recording meters, etc. The overhead five-ton travelling crane was supplied by Messrs. Porte and Co., of Dublin. Travelling rails are laid along the whole length of the new engine-room. The whole of the private lighting cables have been manufactured and laid by the Western Electric Company, of North Woolwich, and are insulated with impregnated paper and lead-covered. The feeder cables are of the triple-concentric type, lead-covered, jute-served, and drawn into conduits, spare ducts being provided for additional cables when required. Three-core, lead-covered, jute-served pilot cables are also drawn into the conduits from the works to the various feeding points. The distribution cables are of the three-core lead-covered pattern, laid in earthenware troughs which are filled with bitumen and covered with bricks. The distribution cables are split up into sections by means of 110 intersection boxes and seven fuse and feeder pillars. A few Nernst lamps have been placed in the streets. The outside work included in the cables contract has been supervised by the assistant electrical engineer, Mr. B. Mertens, A.I.E E., and carried out under the superintendence of Mr. H. J. Holder, A.M.I.E.E., of the Western Electric Company.

PROVISIONAL PATENTS, 1904.

SEPT. 5.

19109. Improvements in single-phase commutator motors. Franklin Punga, Oswaldstre House, Norfolk-street, Strand, London.

19113. Wireless telephony. John Alexander Steven Arnold, 55, Chancery-lane, London.

19125. Improvements in brush-holders for electrical machines. Benjamin Garver Lamme, the Westinghouse Patent Bureau, Westinghouse-building, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, Sept. 16, 1903, being date of application in United States. (Complete specification.)

19126. Improvements in or relating to dynamo-electric machines. William Horace Foot, Westinghouse Patent Bureau, Westinghouse-building, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, Sept. 16, 1903, being date of application in United States.) (Complete specification.)

19139. Improvements in electric arc lamps for medical purposes. Wilhelm Sedlbauer, 46, Lincoln's-inn-fields, London.

19160. Improvements in telephone cord. Ernst Gustaf Sievert, 18, Southampton-buildings, Chancery-lane, London. (Complete specification.)

19168. Improvements in and relating to alternating-current and electrical machinery. William Phillips Thompson, 322, High Holborn, London. (Berliner Maschinenbau Act.-Ges. vorm. L. Schwartzkopff, Germany.) (Complete specification.)

SEPT. 6.

19189. Improvements relating to signal lights for tramway or street cars and for similar services. Sydney Weiss Mitchell, 18, Southampton-buildings, Chancery-lane, London.

19198. Improvements in the construction of lifeguards applicable to electric tramcars and the like. John Nathan Fidler and Samuel Woolley Fidler, 4, St. Ann's-square, Manchester.

19232. Improvements in or relating to electric arc lamps. André Blondel, 111, Hatton-garden, London. (Date applied for under Patents Act, 1901, Sept. 9, 1903, being date of application in Belgium.) (Complete specification.)

19242. Improvements in and relating to electric light fittings. Henry Lea and Sydney Mitchell, 18, Southampton-buildings, Chancery-lane, London.

19243. Improvements in and relating to electric generator locomotives and the like. Alfred Dickenson and John Mannheim, 18, Southampton-buildings, Chancery-lane, London.

19245. Improvements in automatic signalling for electric railways or tramways. Reginald Page Wilson and Arthur Grotjan Marshall, Norfolk House, Norfolk-street, Strand, London. (Complete specification.)

19265. Improvements in indicating devices for electrical fire-alarms. Reinhold Hoenicke, 18, Buckingham-street, Strand, London. (Complete specification.)

19266. An new or improved galvanic cell. Rudolf Ziegenberg, 18, Buckingham-street, Strand, London. (Complete specification.)

SEPT. 7.

19305. Improved electric interlocking apparatus for operating electrically-worked signals and points. Edmond Meyer Tudor Boddam, 55, Chancery-lane, London.

19326. Improvements connected with electric hand-switches for motor cycles and other like purposes. James Frederick Janes, 40, Chancery-lane, London.

19333. Improvements in means for eliminating the effects of induction in telephone systems and the like. John Young, 322, High Holborn, London.

19334. Improvements in electric motors. The Firm of Reiss and Klemm, 6, Lord-street, Liverpool. (Date applied for under Patents Act, 1901, Oct. 12, 1903, being date of application in France.) (Complete specification.)

SEPT. 8.

19341. An improved bearing for use on motors, dynamos, or other machines. Thomas Haynes, 114, Fentham-road, Erdington, near Birmingham.

19343. Regulating trolley head for electric cars. John Murphy, James Murphy, and Philip Goodier, 321, Cleveland-street, Birkenhead.

19364. Combined driving gear and brake for electric cranes. John William Branston, 30, Forester-avenue, Bathwick, Bath.

19365. Improvements in and connected with metallic conduits for electric wires and cables. William Herbert Isherwood, Carlton Mills, Leeds.

19422. Improvements in regulating mechanism for arc lamps. Herbert John Haddan, 18, Buckingham-street, Strand, London. (Allgemeine Beleuchtungs und Heizindustrie Act.-Ges., Germany.) (Complete specification.)

SEPT. 9.

19423. Improvements in the internal insulation of tubes and fittings for electric conduits. Thomas Taylor, Electric-avenue, Witton, near Birmingham.

19465. Improvements in and relating to crossings of tramway rails. Barnim Kombst, 81, High Holborn, London. (Complete specification.)

19475. Improvements relating to electric cranes or the like. Oliver Imray, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens Schuckertwerke G.m.b.H., Germany.)

Digitized by Google

19478. Improvements in regulators for electric circuits. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

19479. Improvements in electric meters. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

19482. Improvements in electric automatic block signal and safety systems. George P. Finnigan, 53, Chancery-lane, London. (Complete specification.)

19560. Improvements in electric meters of the mercury electrolytic type. Arthur Wright, Norfolk House, Norfolk-street, Strand, London.

19562. Improvements in electrolytic meters for alternating currents. Arthur Wright and Herbert Flaxman Reason, Norfolk House, Norfolk-street, Strand, London.

SEPT. 10.

19506. Improvements in connection with wall sockets and switches for electric circuits. George Edwin Fletcher, 17, St. Ann's-square, Manchester.

19525. Improvements in and relating to electromotors. Adrian Baumann, 65, Chancery-lane, London. (Date applied for under Patents Act, 1901, Sept. 12, 1903, being date of application in Germany.) (Complete specification.)

19540. An improved combined rail and road electric tramway system and vehicles therefor. John Dixon and Thomas Oliver Dixon, Lloyds' Bank Buildings, Canute-road, Southampton.

19561. Improvements in and relating to trolleys for electric tramways. Josef Honnette and Heinrich Gebhardi, 81, High Holborn, London. (Complete specification.)

19572. Improvements in means for controlling circuit breakers. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

19573. Improvements in train control systems. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

19574. Improvements in motor-control systems. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

19580. Improvements in electric meters. Thomas Duncan, 7, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Dec. 29, 1903, being date of application in United States.) (Complete specification.)

19590. An improved casing or conduit for electric conductors. Malcolm Macdonald McHardy, 40, Chancery-lane, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Sept. 29, 1904.

1903.

19251. Electric telegraphy. Brown.

19341. Apparatus for use in laying pipes for sewers, drains, electric light, gas and water mains, and such like. Hayes.

21227. Lifeguards for electric tramcars and other road vehicles. Turner and Turner.

21315. Steps for electric and other tramway cars, vehicles, and the like. Cable.

21930. Electric arc lamps. Hulsart and Adams.

23359. Sparking plugs and the like for electric ignition. Veulle.

23540. Electric resistance boxes. Adams and Curtis.

23636. Raising and lowering electric arc lamps. Brown.

25022. Couplings for electrical conduits. McMurtrie. (Date applied for under International Convention, Nov. 21, 1902.)

1904.

8540. Printing telegraph receivers. Swift.

10688. Device for grinding commutators. Bohm.

12368. Installation and apparatus for automatically putting alternating-current transformers into or out of circuit. Mariage.

17190. Manufacture of electric glow lamps to represent candles. Gimingham.

NOTES.

The Mont Blanc Electric Railway.—A few weeks ago we gave the terms finally decided upon for this concession, and we are now able to supplement that information by the following details in regard to construction. The curves must not have a smaller radius than 164ft. Steel rails, weighing at least 58lb. to the yard, are to be placed on metal sleepers, which will be situated at a minimum interval of 2·95ft. The gradient is 1 in 4. The trains will be composed of two or more carriages, but the total length must not exceed 65·6ft.

An Itinerant Post Office.—Milan has just witnessed an innovation in the form of an itinerant post office. A car divided into two compartments is used for this purpose. In the foremost compartment the motors and accumulators for driving the vehicle are stored, and in the after division the Post Office employés carry out the work of sorting. The car performs a tour of some 14 miles and collects the letters from the various pillar boxes, the time occupied approximating an hour and a half. The men sort and stamp the letters *en route*, and deposit them, ready for delivery by the local postman, at the different branch offices. The cars are the work of Messrs. Camona, Giussani, Turinelli, and Co.

Long-Distance Wireless Telegraphy. — It is reported that communication has been established between St. Louis and Chicago, a distance of 300 miles, by the De Forest wireless telegraph, the apparatus working with perfect accuracy. In an interview at New York, Mr. Marconi stated that he will start for Italy on a voyage eastward shortly, keeping in touch with the station at Poldhu as long as possible, with the object of determining the strength of his new transmitters and receivers. Mr. Marconi is not a pessimist, and he is credited with the prediction that he will be able to communicate with Poldhu when half way round the globe.

Rebertson Electric Lamp Works' Concert.—The football club attached to this establishment is holding a concert to-morrow night at 7.30 in aid of the club funds. Proceedings will commence at 7.30 prompt, Mr. C. Wilson, who fulfils the office of president, being in the chair. A lengthy and engaging programme has been organised, and the artistes will be reinforced by a professional contingent Mr. A. Heden, assisted by Mr. P. Pring, will be in charge of the stage arrangements, and Mr. Brown will officiate at the piano. The "turns" comprise songs humorous and sentimental, instrumental music, and a comic performance, so that the audience will be provided with a capital evening's entertainment.

Tramcar Obstruction.—No one desires to see an arbitrary assertion of their rights on the part of tramway proprietors, but when the driver of another vehicle wilfully impedes progress by continuing to crawl along the lines after the gong has sounded he becomes a public nuisance, and merits all the penalties which the law can inflict upon him. A conspicuous case of this kind occurred last week in the New Cross-road, where the driver of a vehicle, despite frequent warnings to clear the lines, kept in front of the car for half a mile, and aggravated the offence by returning to the lines when the car resumed its journey after pulling up at a stopping point. The man's conduct was obviously of a most deliberate character, and fully warranted the fine of £3, with 23s. costs, imposed by the magistrate at Greenwich Police Court. It is a rather favourite method with some defending advocates to make a bid for public sympathy by satirising upon tramway "monopoly" of the highways. Such practices are really puerile. Tramway proprietors merely claim protection against such acts as the above, and, even apart from the rights of the owners, the interests of the public demand that such protection shall be afforded.

Sources of Tramway Revenue.—The Heywood Corporation has not yet come to terms with Bury and Rochdale in regard to its trams, but some of the ratepayers are considering how the service can be utilised to the greatest advantage, and one of them writes to a local paper suggesting that it might be employed for the conveyance of agricultural produce, in addition to coal and ordinary parcels. Goods traffic has been dealt with by the South Lancashire Tramways Company for some years, and two or three of our tramway systems have introduced the carriage of parcels with considerable success, whilst Huddersfield has now matured its coal-haulage scheme. The subject has been dealt with at length in the technical Press, Mr. J. E. Waller contributing a large quantity of original matter. There is a wide field for such traffic, and where powers can be obtained it is a good way of improving a tramway's load factor.

Municipal and Company Relations.—There is a sense of the ludicrous about the incident, reported in these columns last week, connected with the tramways at Handsworth, but it also has a more serious side. The company's action looked remarkably like an attempt to steal a march upon the Council; and even if, as the company state, the junction of the electrical equipment is outside the Handsworth boundary, and the company merely intended to run a car for test purposes, they might at least have notified the authorities. Incidentally, it may be wondered—the company's object being so innocent—why the small hours were selected for the connecting-up operations. Probably no great harm would have been done if the cars had run over the whole system, but the conduct of the company was certainly irregular, and such episodes are apt to accentuate the friction between municipalities and companies. Happily, in this case the salutary lesson of the steam-roller is likely to lead to a better understanding in the future.

The Electro-Harmonic Society.—The nineteenth season of this institute is approaching, and arrangements have been concluded for again holding the concerts in the King's Hall of the Holborn Restaurant. For smoking concerts Oct. 14, Dec. 9, Jan. 20, and March 24 next have been fixed; the ladies' nights being Nov. 11 and March 24. Members are reminded that the annual subscription of 10s. 6d. is payable before the first concert. Extra tickets, price 2s. 6d. for the smoking concerts and 1s. for ladies' nights, may be obtained from the hon. secretary, Mr. W. E. Lane, whose address is now 123, Cannon-street, E.C. Mr. R. K. Gray has kindly accepted the position of hon. treasurer, rendered vacant by the resignation, on account of advancing years, of Mr. Augustus Stroh, who occupied the office since the society's formation. The committee trust that the heavy expense involved in engaging the King's Hall will be justified by a corresponding increase of membership. May harmony continue to reign supreme at these entertaining functions!

Single-Phase Electric Traction.—We understand that the consulting engineers of the London and North-Western Railway and also of the London, Brighton, and South Coast Railway are investigating the advantages of the single-phase alternate-current motor for heavy traction work This motor, if the advantages claimed for it can be realised, will greatly simplify and cheapen the cost of converting main-line railways. In the first place, the current is conveyed from the power station to the train without

Digitized by Google

the interposition of any transforming apparatus. The transformers needed to bring the voltage down to working limits will be carried on the train itself. The cost of construction with overhead wires is thus reduced very largely as compared with the cost of the third-rail system at medium pressures. We understand that the British Westinghouse Company are experimenting in this country on the single-phase system, and that they are laying down experimentally a short length of track at their Trafford Park works, the equipment for working which will be completed within the next two months. This will enable English engineers to judge for themselves the progress made in America with the single-phase commutator motor.

Cambridge Tramways.—As will be seen from our business columns, the Cambridge Corporation have decided on the advice of their consulting engineers, Messrs. Kincaid, Waller, Manville, and Dawson, to allow the Cambridge Electric Tramways Syndicate, Limited, to electrify the Corporation tramways subject to the following conditions, which are of much interest. The Corporation, having waived their right to acquire the tramways in 1907, may acquire them in 1914, upon a valuation as a going concern, provided the sum the Corporation shall pay shall not be less than the amount the company have *bonâ fide* expended on the undertaking, including the purchase of the existing tramways and the cost of obtaining the Bill; in 1925, upon a valuation as a going concern without any further proviso; or in 1947, and after, under the terms specified in Section 42 of the Tramways Act, 1870, or any modification thereof as may be made by Parliament. The Corporation also shares in one-third of the net profits after 5 per cent. on the capital has been distributed amongst the shareholders, and an amount to be agreed has been provided for depreciation and reserve. These terms seem reasonable to all concerned, and they give the company a fair opportunity of seeing a return for their outlay. As will be seen from our business columns, the tramways are to be considerably extended on electrification.

Northampton Institute.—With September on the wane signs of activity among the technical institutions are very noticeable. The Northampton Institute has just issued its syllabus, which promises well for a continuation of the valuable work performed by this foundation. Under the direction of Dr. R. Mullineux Walmsley and his able assistants, the evening courses in electrical and mechanical engineering will be resumed on Monday next, as also will the courses in artistic crafts and other technological subjects. The evening courses in electrical engineering have been remodelled, the complete course now covering five years. The day studies in engineering, extending over four years, will begin on the 3rd prox. In the electrical section special attention is devoted to traction and electrochemistry, in addition to the ordinary work in lighting and power distribution. The institute's system of combining the theoretical and practical sides is well known. It is believed that the complete day courses in technical optics, included in the institute's programme for the first time, are the first attempted in any country. The evening classes in this section are separated from the applied physics department, and have been remodelled under Mr. S. D. Chalmers. Day courses for artistic crafts also appear for the first time. The admirable methods in vogue at the Northampton Institute will doubtless commend it to those contemplating a technical career.

An Automatic Telephone Exchange.—In the Berlin Imperial Postal Museum has been installed a model of an automatic telephone central station. In order to allow of the working being watched readily, the exchange has been placed in a glass case. It is actuated by putting at the speaking station a finger into a disc perforated with numbered holes and turning the disc up to a certain point, when a group distributing switch will first be moved in the exchange, the connections being divided into groups according to the decimal system. As soon as the adjustment by means of the finger is repeated, for the next small number a secondary group and, finally, a line distributing switch (*linienwähler*) will be actuated. In the central station installed in the museum four groups of two-line distributing switches have been connected together, being of the same size as in the exchange existing in Berlin. The telephonic apparatus themselves have also been adapted to German practice. As soon as a call is made the apparatus is seen to work rapidly and safely, any connections being effected at a surprising rate. In fact, the exchange will at any time be ready and prepared to serve any subscriber. In the case of the number called for not being disengaged, this is signalled by a cracking noise in the receiver. By placing the receiver on its hook, the connection is instantly broken, all being ready for a new connection. There is practically no noise in the working of the exchange, and instead of conversations there is only heard the slight humming of the interrupter for the working current.

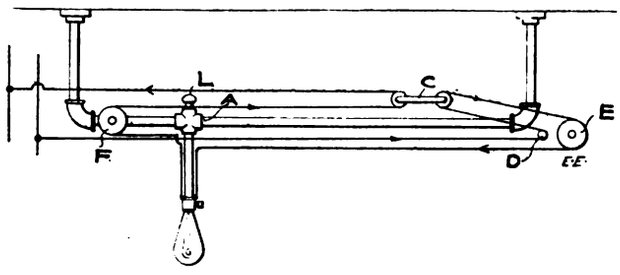
The Birkbeck College.—This institution, which is located at Bream's-buildings, Chancery-lane, and has now completed 81 years of educational work in the Metropolis, commences the new session on Monday, Oct. 3, when Dr. J. E. Mackenzie will give the opening address at 7.30 p.m. The day and evening courses of study comprise the various branches of natural science (chemistry, physics, botany, zoology, geology, etc.), mathematics, Latin, Greek, modern languages, economics, commercial subjects, law, logic, and psychology. Courses, conducted by recognised teachers of the university, provide for the examinations of the University of London in the faculties of arts, science, and commerce. The report for the last session shows that during the year 71 students passed some university examination, while a large number gained successes at various public examinations. Special classes prepare for the conjoint Board and Civil Service examinations. The college has added considerably to it appliances in recent years, and the physical, chemical, biological, and metallurgical laboratories are very thoroughly equipped. Courses in mining, metallurgy, and assaying are given both in the day and evening. The modern language classes include Russian, Spanish, Italian, and Dutch, as well as French and German. The college has a school of art, open both day and evening. Good reading and magazine rooms are provided. The calendar supplies much detailed information respecting the courses of study, examinations, studentships, etc. A popular lecture or entertainment is given in the theatre every Wednesday evening during the session.

Theatre Lighting in America.—The terrible fire at the Iroquois Theatre in Chicago last December has led to a general overhauling of the theatres in that town in an attempt to "close the stable door after the horse has escaped." Our contemporary, the *Western Electrician*, describes the new equipment for electric lighting at the Alhambra Theatre, and some of the provisions clearly show that the authorities have a knowledge of the London County Council's regulations governing such work. For instance, there are two centres of distribution in the building, one on the stage and the other in the box office. In the event of a fire on the stage, the throwing of a switch in the box office will connect all the lights in the lobbies and exits on to an outside supply system. This renders it practically impossible for the theatre to be left in darkness for any length of time. When lights are needed in the

Digitized by Google

ordinary way, the whole of the theatre lights are supplied from its own plant. The wiring in the building is carried out on the separate-circuit principle, no more than a dozen 16-c.p. lamps being allowed on one circuit. It will be seen that the limit is considerably higher than that recognised as the best work in this country, where six or seven lamps is about the limit. All the wires are installed in loricated iron conduits, and are so arranged that they can be used either on the two or three wire system. The switchboard for controlling the stage-lights and varying the candle-power of the same resembles the usual English type, as it contains provisions for the linking of the dimmers, and a number of circuits so that they may be operated simultaneously. The switchboard is iron-clad, and is said to be waterproof as well as fireproof. Intercommunication telephones, the wires for which also run in iron conduits, are provided, connecting the box office, the fly gallery, and the orchestra with the stage electrician. The electrical work at this theatre, although good, does not seem to be any better than that insisted upon in London for the last five or six years.

Lamp Suspension over Work Bench.—Mr. W. F. Sheaf, of Herkimer, New York, is responsible for the following illustration, for which we are indebted to the *Western Electrician*, of a method of suspending an electric lamp over a desk, work bench, lathe, etc., in such a way that the light may be moved from one end of the work bench to the other, without any loose wire. The contrivance also allows the lamp to be placed out of the way when not in use. The frame is made of ¼in. or ⅜in. pipe, attached to the ceiling by floor plates. A represents a pipe-cross drilled out so that it will slide upon the pipe,



with a thumb-screw (L) threaded through a pipe plug and used to fasten the lamp up out of the way when not in use, and also to fasten it at any angle when in use. The arrows indicate the direction of the current in the lamp cord. Two movable pulleys linked together are shown at C. D is a porcelain knob to which the lamp cord is tied, and E and F are fixed pulleys. The lamp and movable pulleys, C, move in opposite directions. As one cord lengthens, the other shortens, and *vice versâ*. The device is ingenious, but the number of wires and pulleys employed makes one doubt the practicability of the same for a work-shop. We are afraid that in England, at any rate, the hooking up of a flexible cord will still hold the field for this purpose.

The Lynchburg Trolley Ear.—For the last eight months the Lynchburg (Va.) Traction and Light Company have been using with very satisfactory results the new type of trolley ear devised by Messrs. S. H. Cochran and A. E. Anderson, of which a description is given in the *Street Railway Journal* of New York. The ear is adapted for both round and grooved wire. The cap of the ear is provided with a depending post, having a wedge-shaped slot cut through it near its lower end. The lower end of this post is cut away and provided with a rounded shoulder, and the extreme lower end is also cut away to provide a shoulder and a downwardly projecting lip. The ear is substantially U-shaped in cross-section, and upon its lower face is straight from end to end, but the inner bottom face of the ear is convex. The ear is provided with an arm extending upward and terminating in a tubular-shaped portion, which is provided with a bevelled bearing face. The bottom of the bore of the tubular division is rounded to form a seat. Both the tubular extension and the post are furnished with slots arranged to coincide and permit the insertion of a key. This key is provided with a set of perforations, through any of which the key can be locked by the insertion of a cotter-pin. A wedging piece is formed in substantially the same arc as the convex face of the ear. This wedging piece is provided in its upper edge with a notch in which the shoulder of the post is adapted so as to be seated when the parts are assembled for locking. In using the ear the trolley wire is deflected and placed within the ear. After the wire is in the ear, the wedging piece is placed in it, with its curved face resting upon the upper face of the wire. The ear is then pushed upward, and the tubular extension passes over the post until the shoulder of the latter engages with the notch in the wedging piece, the lip of the post bearing upon the outer face of the wedging piece, and thereby holding it firmly in position. The key is then inserted and locked. Should the key for any reason come out of the post, the ear would fall to the ground and leave the trolley wire free from any obstruction. Actual tests have shown that the ear can be removed from and replaced on the wire in two minutes. A modified form of construction is adapted to grooved or figure 8 wire.

The Electrical Production of Steel in Sweden. Those furnaces in which the direct heat of an arc formed between an electrode and the iron in the furnace is employed are handicapped by the fact that the temperature of the arc is in the neighbourhood of 3,700deg. C., which is much more than is necessary to melt steel, consequently the metal close to the arc becomes burnt before that further off is melted. Another type of furnace that has occasionally been tried depends on the heat developed in the steel itself by the passage of a heavy current. The low resistance of the metal in the molten state, however, necessitates the use of enormous currents with such furnaces, and this leads to trouble at the electrodes and great expense in the copper supply mains. According to the *Elektrotechnische Rundschau*, an improved furnace, depending on the induction principle, has been at work for some time past at Gysinge, in Sweden, with very satisfactory results. The smelting chamber consists of an annular cavity, coated inside with firebrick and closed at the top by lids which are preferably on the floor level. Through the centre of this ring one limb of a rectangular transformer core passes, the remainder of the core being completed beyond the ring. The core is, in fact, linked with the annular cavity like one link of a chain is looped with the next. The primary winding of the transformer is placed immediately round that limb of the core which is surrounded by the annular chamber. A single-phase alternating current is passed round this primary winding, and induces a flux in the iron core, which, in turn, sets up a current in the material to be melted, the value of this secondary current depending on its primary voltage and the primary turns. The first of these furnaces was set up in 1900, and produced steel excellent in quality, but at a slow and expensive rate, the output being only 595lb. of steel in 24 hours with a power expenditure of 78 kw. A few months later a second improved furnace was erected which gave 1,320lb. to 1,540lb. per 24 hours with 58 kw. In 1902 the matter was taken up on an enlarged scale, and has been working satisfactorily ever since. The capacity of the new furnace is 3,960lb., and out of this only about 2,200lb. to 2,420lb. is drawn off at a time, so

Digitized by Google

that the secondary circuit is never quite broken. The rate of production is 9,050lb. of steel per 24 hours with a a power of 165 kw. The supply is obtained from a 3,000-volt single-phase generator, and the secondary current through the steel is about 30,000 amperes. The steel produced is of exceptionally good quality, and unusually dense and homogeneous. It can be readily worked cold, and is less liable than ordinary steels to spring or become distorted when hardened.

New Publications.—Messrs. Cassell and Co. have forwarded us a copy of "Electricity in the Service of Man," upon which Dr. Walmsley has been engaged for some three years past. This is the fourth edition, which, owing to the advance of electrical science since the previous issue was published in 1893, has been practically re-written from cover to cover. It has already circulated in serial form, the first number making its appearance in October, 1901. In issuing the present volume the author was confronted with the problem of inadequate space, for, though the extent of the work has been increased by nearly 200 pages, bringing the total up to 1,200, the recent rapid progress of the science presented an extensive and diversified field. Dr. Walmsley was therefore compelled to choose between treating the various branches in an abbreviated form and dealing fully with a portion only of the work originally contemplated. Finally, he decided upon the latter plan, thinking that if the reception of the present treatise be favourable, a supplementary volume, dealing with the omitted branches, might be issued in the near future. The work is divided into two sections. In the first, the author deals with the history and principles of electrical science; and the lucid manner in which it has been compiled, supplemented by copious and graphic diagrams, will render it eminently comprehensible to the student, or even to the lay mind. The second part, dealing with the technology of electricity, will be vested with interest for members of the profession, comprising, as it does, an account of recent developments on the practical side, accompanied by full discussions of the underlying principles involved and the methods available for utilising them. After treating in detail generators and motors for both continuous and alternate currents, the volume concludes with a chapter on electrical measurements, in which most types of modern instruments are included. This section, too, is splendidly illustrated, and purchasers of Dr. Walmsley's admirable production will obtain a good return for their 10s. 6d. The author records his indebtedness to many friends and manufacturers, and also to the technical Press, for the assistance accorded him.—"Carpentry Workshop Practice," by C. F. and G. A. Mitchell. (London: Cassell and Co.). 1s. 6d. An excellent little manual—one of the Polytechnic series—specially prepared for students following recognised courses, and also adapted to the needs of the large body of votaries unable to pursue organised instruction. The Year Book of the Michigan College of Mines has just come to hand. This foundation was established under statutory authority in 1885, and provides specialised courses in the different branches of mining engineering. It is particularly happy in its location, being situated in the midst of the great mining region of Lake Superior, and practical work is a dominant feature in the programme of the college, which during the past year received an accession of 231 students. Many of the high schools are affiliated to the college, admission to which is gained by passing a preliminary examination or producing a diploma from an accredited institution, while special arrangements are made for the reception of students who have not undergone an academic preparation. Highly interesting descriptions of the college buildings and equipment, the library, text-books, and degrees are contained in the volume, and the detailed syllabus for the ensuing session augurs well for the continued success of the college. While it does not guarantee appointments, the college takes a close interest in the future welfare of its graduates, and the Year Book is supplemented by a register containing a complete list of their qualifications.—"Journal of the Western Society of Engineers (Chicago)." The issue for August contains a paper by Mr. G. S. Rice on "The Use of Steel for Coal Mine Tipples, and a Classification of Same," and one on "Railroad Signalling," by Mr. G. E. Ellis, with the discussions thereon. Mr. A. N. Talbot deals with "Flexure of Reinforced Concrete Beams," and Mr. E. B. Elliott describes some of the electrical features of the St. Louis Exhibition.

Electric Waves.—At the recent Cambridge meeting of the British Association Dr. J. A. Fleming presented to Section A his paper on "The Propagation of Electric Waves along Spiral Wires and on an Appliancé for Measuring the Length of Waves used in Wireless Telegraphy." This paper is concerned with an experimental and theoretical treatment of the propagation of electric waves along spiral wires. The subject has engaged the attention of several physicists. Hertz has described an experiment in which he established stationary electric waves on a spiral wire and compared the distance of the nodes with the corresponding distances when the wire was stretched out straight. Theoretical treatment has been given by H. C. Pocklington, and G. Siebt has devised lecture apparatus for exhibiting the propagation of stationary waves on spiral wires. The first experiments described by the author were made with a long helix of insulated copper wire, wound in one layer on a wooden rod. The helix consisted of 5,000 turns, the length being 200cm. If such a helix is placed in connection with an oscillating circuit consisting of a condenser or Leyden jar, a spark gap, and a variable inductance, stationary waves could be set up on the helix by adjusting the inductance in the oscillating circuit. In order to detect the nodes and antinodes of these stationary oscillations, the author makes use of a vacuum tube, similar to that used in spectrum analysis, preferably one filled with the rare gas, neon, which was kindly supplied to him by Sir William Ramsay. Rarefied neon seems to be extremely sensitive to the presence of variable electric force through it; hence, if such a tube is held perpendicular to the helix and moved parallel to itself along it, it glows brightly at the antinodes but not at the nodes. In this manner the internodal distances can be measured with considerable accuracy, and the wave-length of the stationary oscillation measured. The paper also contains a theoretical analysis of the phenomena leading to the conclusion that the velocity with which the wave is propagated along the spiral is inversely proportional to the square root of the product of the capacity and inductance of the helix per unit of length. The author has perfected of late years methods for measuring very small capacities and inductances, and in the case of the above-named helix the inductance is equal to 100,000cm. per centimetre, whilst a capacity of the helix is $\frac{7}{40}$ of a micro-microfarad (one micro-microfarad $=10^{-6}$ microfarad) From these data the velocity of propagation of electric waves along the helix can be shown to be 235,000,000cm. per second. This figure is confirmed in the following manner: The capacity and the inductance in the oscillating circuit are both measured when the first harmonic oscillation is formed on the helix, and under those conditions the half wave-length was found to be 140cm., whilst the frequency in the oscillating circuit, as calculated

Digitized by Google

from the capacity and inductance, was found to be $0\,847 \times 10^6$. Having, therefore, the wave-length and frequency, we find their product gives a velocity of 235,000,000cm. per second, which agrees with the figure determined from the constants of the helix. It is shown in the paper that the best form of inductance to be employed in connection with the oscillating circuit is a square of one turn of wire, and that the employment of spiral coils leads to errors due to passage of a dielectric current from coil to coil. On the above lines an apparatus has been devised by the author for measuring wave-lengths in connection with Hertzian wave wireless telegraphy. It is a matter of considerable importance to be able to determine the frequency and wave-length of the waves sent out by any given transmitting arrangement. The author calls this instrument a "kummeter." It is constructed as follows: A long ebonite rod is wound over closely with silk-covered wire in one layer, and this is supported on insulating stands. On this long helix slides a metal saddle having some layers of tinfoil interposed to make good contact between the saddle and the helix. This saddle is connected by a flexible wire with the earth. One end of the helix is furnished with an insulated metal plate, which is placed in apposition to another metal plate connected to the oscillating circuit of the transmitter. The process of measuring the wave consists in sliding the saddle along until a Neon vacuum tube indicates the presence of one note half-way between the saddle and the plate. When this is the case, the distance from saddle to plate is one wave-length of the stationary wave on the helix. From the constants of the helix the velocity of the wave along it can be calculated as above shown, and hence the frequency of the oscillating circuit becomes known. If this frequency is divided into the velocity of light, reckoned in feet, it gives the wave-length in feet of the wave radiated from the associated aerial, provided that the aerial radiating wire has been tuned to be in resonance with this oscillating circuit. This instrument also provides the means of measuring small inductances, and also the frequencies in oscillating circuits, which are much higher than those which can be determined by photographing the spark.

Testing a 2,750-kw. High-Tension Alternator and Transformer.—The *Schweizerische Elektrotechnische Zeitschrift* gives a detailed account of some interesting tests carried out on three 10,500-volt, 2,750-kw., three-phase alternators and three three-phase 10,500-46,000-volt transformers of the same output, built by the Maschinenfabrik Oerlikon for the Caffara water-power installation in Brescia. The generators are of the standard stationary armature type, and are wound for 9,000-10,500 volts, 150 amperes, 315 revolutions per minute, 42 periods. Though the maximum volts by the maximum amperes correspond with a load of 2,760 kilovolt-amperes, the normal load is actually only 9,000 volts at 150 amperes, or 2,340 kilovolt-amperes, with a power factor of ·75. The armatures have three open slots per pole per phase, and the coils are former-wound. The pole-shoes are of the slanting form adopted by the firm in order to ensure a sine wave of E.M.F., and the whole pole is thoroughly laminated. Each complete machine weighs some 81,550lb., and the rotating part alone about 29,750lb. With the power available it was not possible to test the machines under load, so the following method of determining the drop, efficiency, and heating was adopted: One alternator was directly coupled to a direct-current motor of about 400 h.p., and the no-load losses and open-circuit characteristics were obtained. This motor-driven alternator was then made to drive the second alternator as an unloaded synchronous motor, and the no-load losses of this synchronous motor were measured by means of a wattmeter placed between the two machines, after adjusting the synchronous motor excitation until the minimum armature current was reached. These motor no-load losses by wattmeter were found to check very closely with the light-load losses of the generator, measured by the aid of the direct-current motor. In order to get an idea of the increase in the core and eddy-current losses with load, the excitation on the generator was next increased and that on the synchronous motor decreased, until the full-load current (150 amperes) was flowing in both armatures, the power factor being practically zero, and the wattmeter measurement was then repeated. It is interesting to note that in order to produce this state of affairs the generator excitation had to be increased to 220 amperes and that of the motor reduced to 72 amperes, the normal full-load excitation with ·75 power factor being 160 amperes. The additional load losses, after subtracting the known $C^2 R$ losses in the armatures, were found to amount to only 4 kw. per machine (the ordinary no-load losses, excluding excitation, being 63 kw. per machine), so that they may be neglected. The commercial efficiency, including exciting losses, of each generator was specified as 95 per cent. at a load of 1,760 kw. with $\cos \phi = 1$, and, using the measured no-load losses, this efficiency works out at 95·8 per cent. The voltage drop was specified as 6 per cent. with $\cos \phi = 1$ and a load of 1,760 kw., and 16 per cent. with $\cos \phi = ·75$ and a load of 2,340 kilovolt-amperes, and the amounts estimated from the observed open-circuit and short-circuit characteristics of the machine were 3·5 and 13 per cent. respectively. The 24-hour temperature test taken at 10,500 volts 120 amperes, with the generator over-excited and the synchronous motor under-excited as above, gave equally good results, the maximum rise on the generator armature being only 28·5deg. C., and on its magnets 14·5deg. C., whilst the specified rise was 35deg. C. The transformers are of the standard Oerlikon oil and water cooled type, the water cooling being, however, carried out in a somewhat novel manner by making the upper part of the cast-iron case double walled, and fitting a number of ribs in the space between the walls, so as to cause the water to circulate up and down between them all round the case. In this way a good cooling effect is obtained without the risk of the water leakage which sometimes occurs with the usual circulating pipes suspended in the oil. The cores consists of three rectangular limbs side by side. The low-tension winding consists of bare flat copper strips insulated with presspahn, and is wound next the core, the high-tension winding being outside. The core losses at 9,000 volts were found to be 20½ kw., and the copper losses at 150 amperes were 12 000 watts, giving an efficiency of 98·5 per cent. at 1,760 kw. $\cos \phi = 1$, or 98·2 per cent. at 2,340 kilovolt-amperes $\cos \phi = ·75$. By means of a short-circuit test the drop was found to be 4·25 per cent. at 2,340 kilovolt-ampere $\cos \phi = ·75$, or ·5 per cent. at 1,760 kw. $\cos \phi = 1$. The wattmeter measurement on the short-circuit test, with 150 amperes passing, showed only 14,000 watts, their comparatively small addition for eddy currents being probably due to the small section of the copper wires. The transformers were tested for heating on open circuit, but with the voltage increased to over 12,000, so that the core loss alone amounted to 32 kw.—*i.e.*, as much as the sum of the core loss and copper loss under normal full-load conditions. In this way it was found that at 2,340 kilovolt-amperes the temperature would be within the specified 45deg. C., with a water circulation of about 23 pints per minute in each transformer. The gross weight of each transformer with oil is 26,500lb., or 22,040lb. without oil.

HIGH-SPEED ELECTRIC RAILWAY EXPERIMENTS ON THE MARIENFELDE-ZOSSEN LINE.*

BY ALEXANDER SIEMENS, PAST-PRESIDENT.

(*Concluded from page 409.*)

Of great importance are the results obtained while accelerating and during the retardation of the cars. The

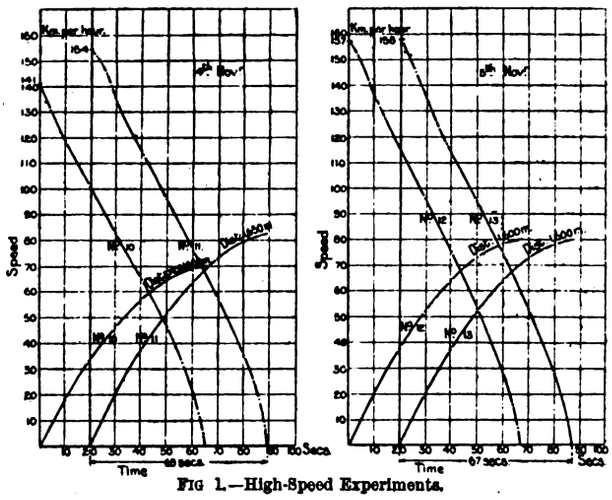

FIG 1.—High-Speed Experiments.

acceleration varied with the demand on the generating station and the motors, as was to be expected. To obtain a speed of 100 km. per hour the distances travelled varied from 2,000m. to 3,200m., and the times from 138 to 220 seconds. These figures correspond to an average acceleration of 0·13m. to 0·2m. per second, and correspond to

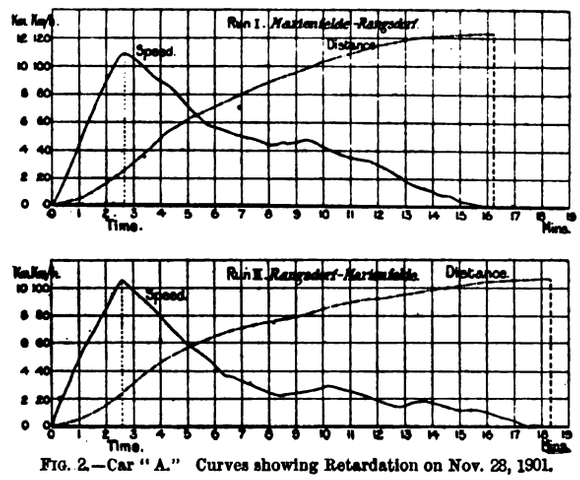

FIG. 2.—Car "A." Curves showing Retardation on Nov. 28, 1901.

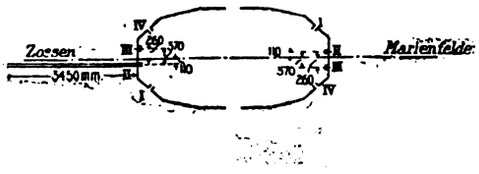
trains intended to travel long distances without stops the rate of acceleration is, however, of less importance than the action of the brakes on which the safety of the service depends. Both cars were fitted with a Westinghouse quick-acting brake, hand brakes, and an electric brake acting by reversing the currents through the motors. The "A" car had, in addition, an accumulator battery, the current from which could be sent through the three-phase motors. A great many trials with these brakes are reported, which are not important enough for recording in detail as the brakes were not satisfactory, but a few curves are reproduced in Fig. 1 showing the results. In Fig. 2 the decrease of speed is shown when the "A" car was left to itself after attaining a speed of about 106 km. per hour respectively. The wind at the time was W.N.W., and had



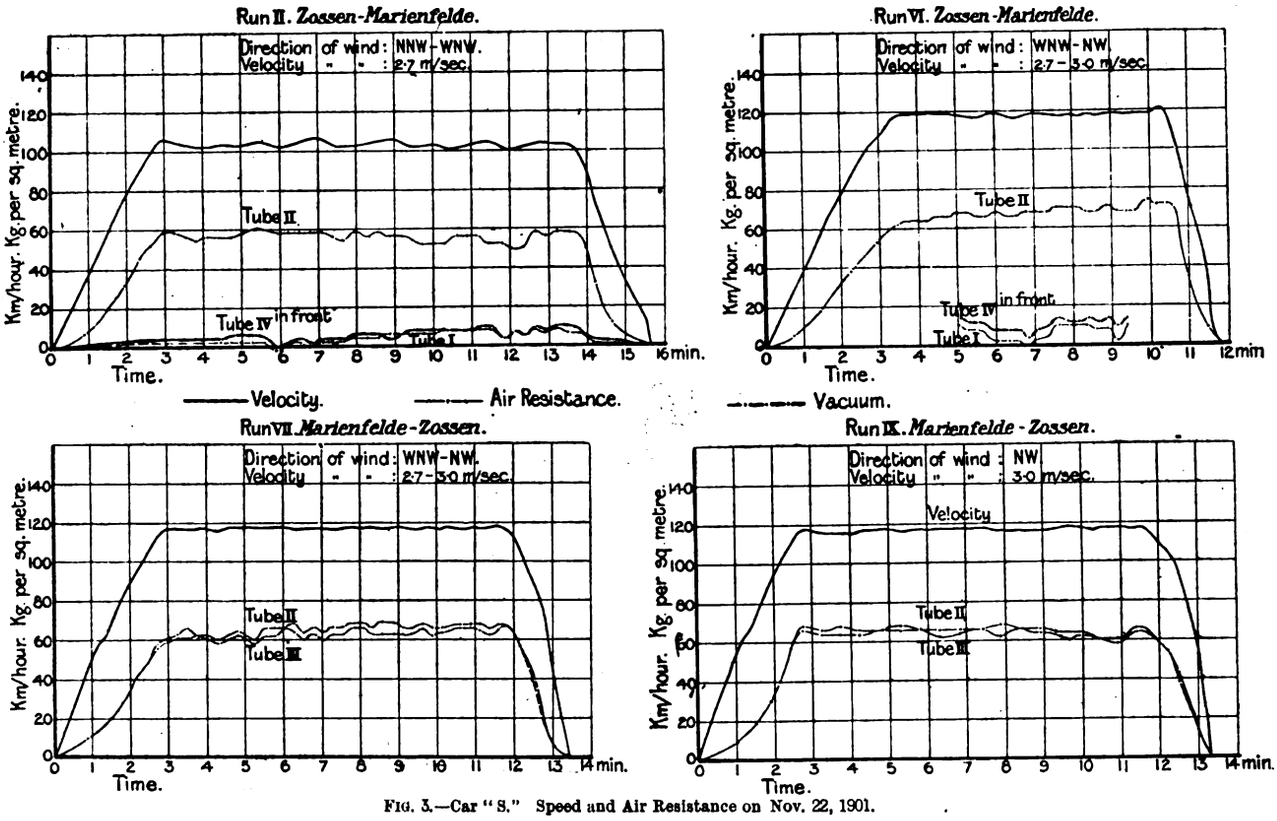


FIG. 3.—Car "S." Speed and Air Resistance on Nov. 22, 1901.

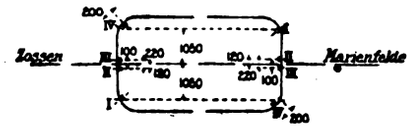
700 h.p. to 100 h.p. As the motors are capable of exerting up to 3,000 h.p. during acceleration, this might have been increased correspondingly, but the generating set was not powerful enough to supply the necessary current. For a speed of 11·4m. per second; it offered, therefore, less resistance during the run from Marienfelde to Rangsdorf than in the opposite direction.

Very numerous observations were made about the consumption of energy, both in the generating station and on

* Paper read before the Institution of Electrical Engineers.

Digitized by Google

the cars, especially during the last set of runs. For this purpose readings were taken at the switchboard in the generating station every 10 seconds of the volts, amperes, and watts, and the periodicity of the current was checked by the number of revolutions of the generating set. On the cars amperes and volts were read at intervals of from



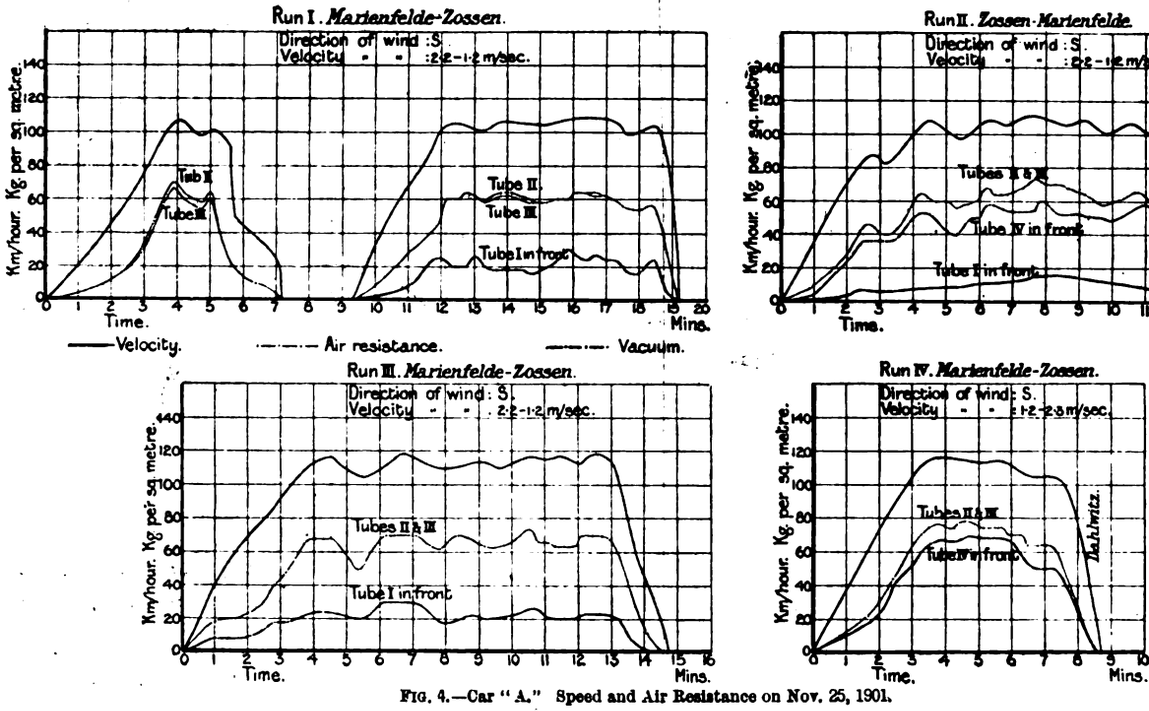


FIG. 4.—Car "A." Speed and Air Resistance on Nov. 25, 1901.

15 to 30 seconds. The measurements at the station were the most accurate, as the instruments there were not exposed to the vibrations unavoidable on the cars. After making the observations they had to be corrected, as the instruments were only correct at a certain periodicity. Numerous further measurements were taken, and the following table gives the average result of the power required at a constant speed.

The report does not consider these figures reliable enough for commercial deductions, partly because the instruments were not properly calibrated for the varying periodicity of the current, partly because the motors in both cars were working very much below their rated output.

For the purpose of observing the air resistance at the various speeds, openings were made in various parts of the car bodies and short brass tubes inserted. These tubes were connected by indiarubber tubes to a row of pressure indicators, consisting of pairs of communicating glass tubes about 5mm. in diameter partly filled with water. An adjustable scale was fitted to each indicator, divided into millimetres, so that the difference in the water-level of the two tubes could be observed at the various speeds. Four such openings were made at each end of either car, two of which were near the centre and the other two at the sides, as indicated in the diagrams of Figs. 3 and 4. Preliminary

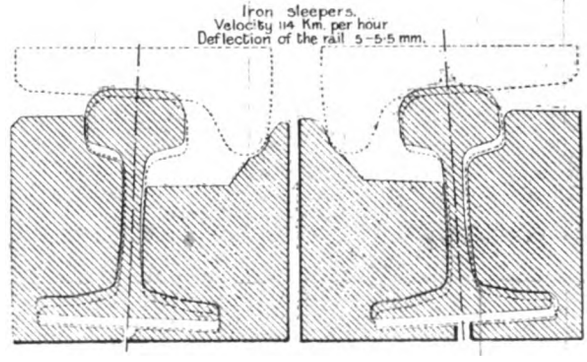

FIG. 6.—Diagram of the Displacement of the Rails on Nov. 30, 1901, at 15·8 kilometres.

Digitized by Google

trials proved that the position and the form of the opening of the brass tubes have no influence on the result, and this made it possible to compare the pressure all over the front of the car with the pressure in the centre, independent of the varying speed of the car. In addition, straight tubes, up to 3·4m. long, were fitted to explore the pressure of the air in front of the car, and these observations showed that a cone of uniform pressure exists in front and at the back

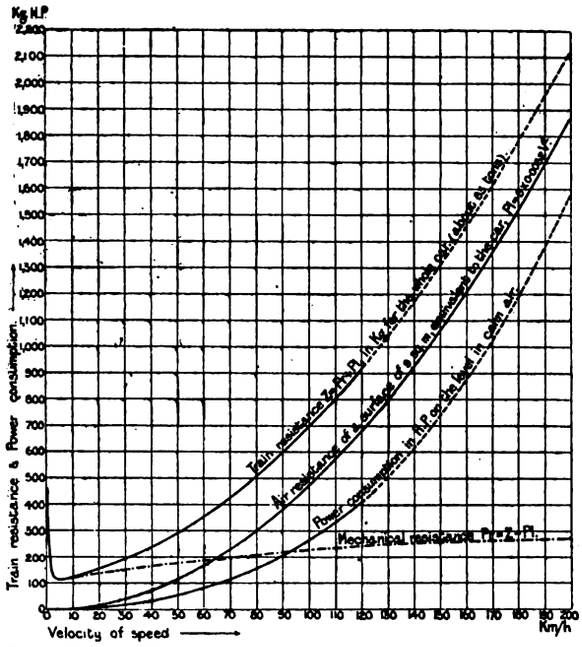

FIG. 7.—Train Resistance and Power Consumption of the High-Speed Cars.

of the car, the apex of which was about 3m. distant from the car. The "A" car, as the diagram shows, has well-rounded corners, while the "S" car has its ends in the shape of truncated cones. The pressure on these was very much smaller than in the centre, and sometimes even negative owing to the influence of the wind. Some openings were also made along the sides of the car, and occasional observations showed that speed had very little influence on the pressure indicated, when the brass tubes ended flush with the sides of the car, and that the direction of the wind has much more effect. The Tables VI. and VII. show the results of observations made during several runs of both cars.

Combining all the results, the report considers that up to a speed of 150 km. per hour the pressure may be calculated by the equation $p = 0{\cdot}07\ v^2$, when v is the velocity in metres per second and p is the pressure on a surface of one square metre at right angles to the direction of the motion. The number of observations were, however, insufficient to determine the best form for the end of the cars. Another set of observations was made to determine the extent of the movement of the rails when the cars

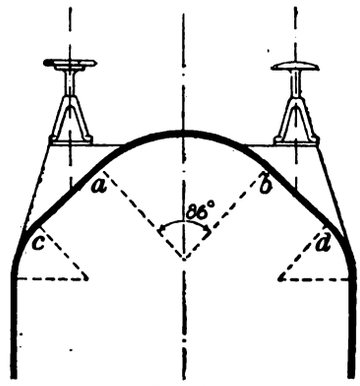

FIG. 8.

were passing at various speeds. For this purpose measuring apparatus were set up at various points of the line, which are shown in Fig. 5. Each of these consists of three strong posts, about 1½m. long, rammed into the ground, one in the centre and one on each side of the rails, to which a strong board is fastened with its upper edge a little below rail-level, and with suitable openings cut to permit the rails to pass through. Near each rail two short boards are bolted to the plank, between which a lead plate is supported. This is cut in two and fitted accurately against the rail, the edges touching the rail being sharpened. It is evident that any movement of the rail will bend these edges back, and thus leave a permanent record of the greatest movement of the rail. The result on one set of lead plates is shown in

* Motor cars. † Military trains.

was also experienced in seeing sufficiently far ahead in rainy weather. It is, therefore, suggested to repeat the signals on the car by visual and by audible means, which should also indicate when the apparatus is out of order. In addition, it is recommended to cut the current off in the sections which a car has just left.

In conclusion, the first report states that, thanks to the care exercised by the firms supplying the cars and outfit, to the cautious and reliable execution of all the electrical work, to the careful maintenance of the permanent way and its appurtenances, and to the conscientious observation of all the precautionary measures, no mishap or damage of any kind has occurred during the trials. No psychological effects on the drivers or

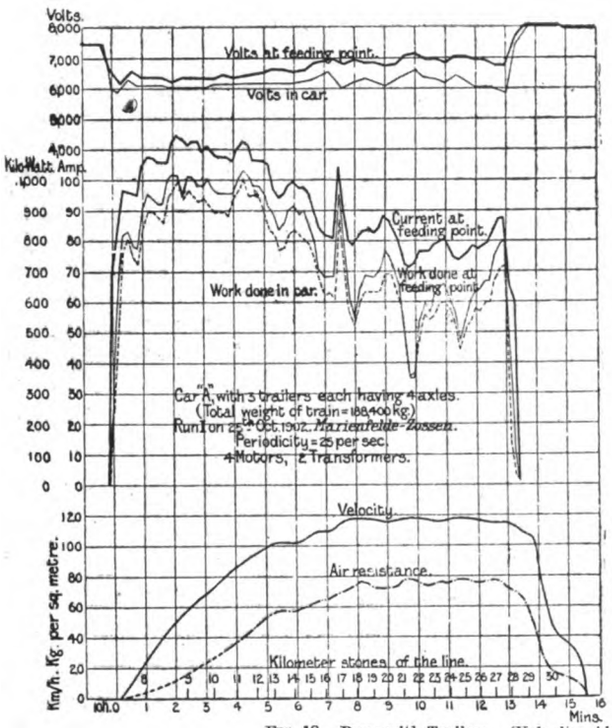
investigated. As the military trains run only at considerable intervals, at a comparatively low speed, the existing signalling apparatus had to be supplemented by distant signals about 2 km. from the stations, and some difficulty

question, some valuable technical information has been gained. In the first place, the experiments have shown that it is possible to collect high-tension currents even in unfavourable weather from overhead conductors at double

Digitized by Google

the speed of the present express trains. Both the conductors and the collectors have worked so satisfactorily up to the present that their efficiency at higher speeds may be safely assumed. Three-phase motors have shown themselves reliable, and their overheating has been prevented by suitable ventilation. It has, however, not been possible to decide whether it is preferable to fix the motor on the axle or support it wholly by springs; nor can it be safely said whether fluid or metallic resistances are the more suitable.



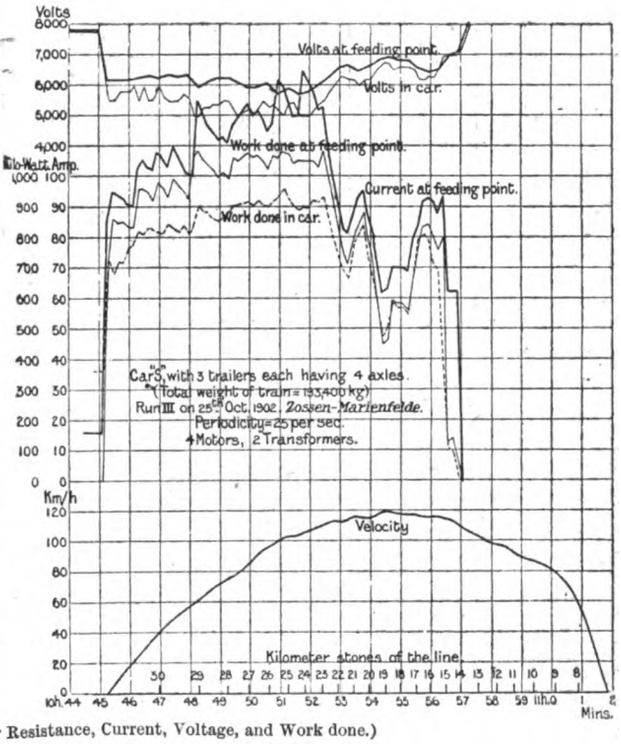


FIG. 12.—Runs with Trailers. (Velocity, Air Resistance, Current, Voltage, and Work done.)

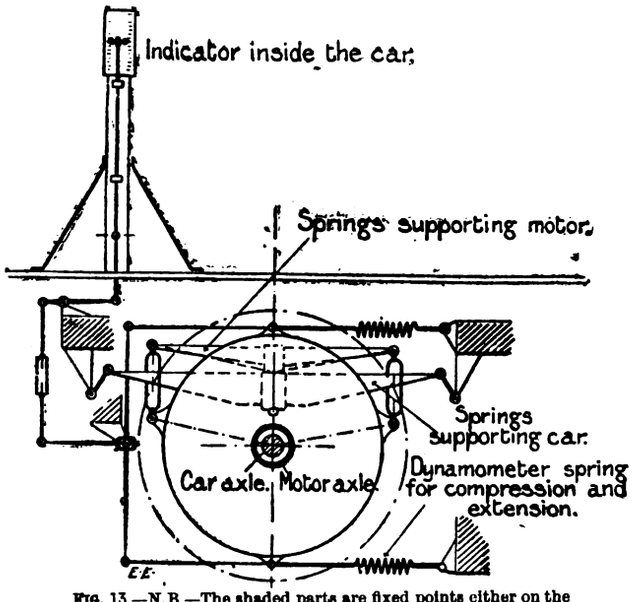

FIG. 13.—N.B.—The shaded parts are fixed points either on the car frame or on the bogie.

Generally speaking, the first year's trials have served principally to find out the best methods of making observations, and to determine which are the most suitable instruments for obtaining trustworthy information. Basing further experiments on the knowledge thus gained, it is certain that it can be ascertained whether the cars, their equipment, and all other outfit are suitable for regular traffic on main lines at a speed of 160 km. per hour, and whether still higher speeds are practicable, especially from an economic standpoint.

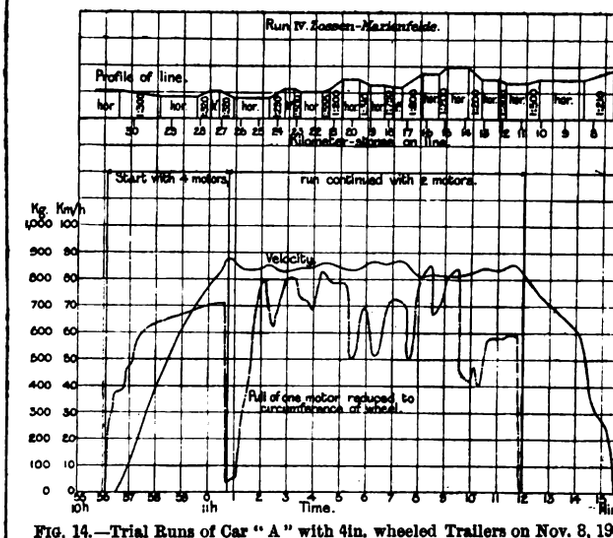

FIG. 14.—Trial Runs of Car "A" with 4in. wheeled Trailers on Nov. 8, 1902. Pull, Velocity, and Profile of Line.

Originally it had been the intention to resume the experiments in 1902 on the lines laid down at the commencement, and to increase gradually the speed of the cars until a speed of 200 km. per hour had been attained. It was, however, not possible to relay the permanent way in time, and in

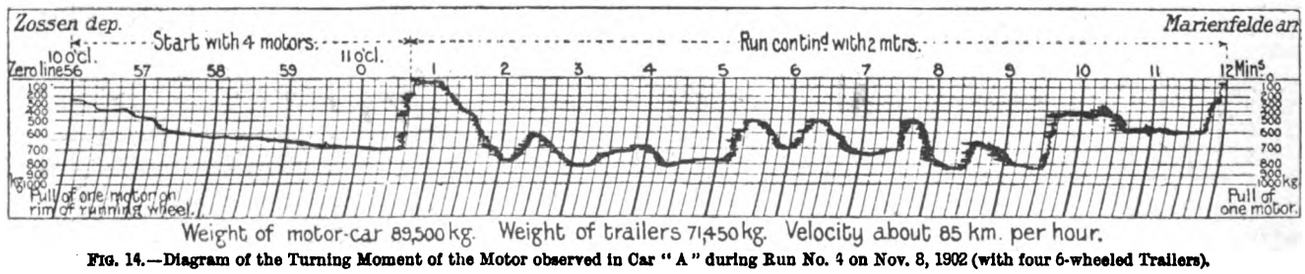

FIG. 14.—Diagram of the Turning Moment of the Motor observed in Car "A" during Run No. 4 on Nov. 8, 1902 (with four 6-wheeled Trailers).

The brakes have not been powerful enough for the high speeds. An alteration of the existing arrangements and the adoption of an efficient electric brake appears to be imperative.

	IV.	47	70·75	360	101 5 103	19	10,770	290	0 82		

consequence of this the authorities would not allow a greater speed than 125 km. per hour. The time was therefore utilised for determining more accurately the resistance of the cars at various speeds, the power required for propelling them, and the losses of energy in the feeder and the conductors. In addition to this, further experiments were made with the brakes, and alterations in the structure of the cars were considered, to ensure steady running at high speeds; the movement of the rails was also observed during the trials.

The second report describes the experiments in great detail, and the following are the principal results ascertained by their help: At first attempts were made to determine the resistance of the cars direct by pulling them at moderate speeds by a locomotive, to which they were attached by a dynamometer. It was found, however, that owing to the great weight of the cars, and owing to the irregular pull of the locomotives, no steady curves could be obtained, nor was the success greater when the cars were attached to a goods train. Somewhat better results were achieved by the employment of a three-phase locomotive, but the curves were still too irregular to be accepted. Nothing

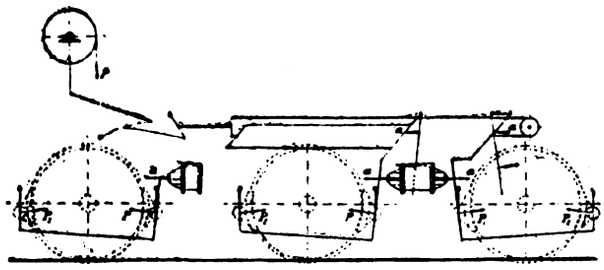

FIG. 15.

remained but to revert to observing the time each car took to come to a standstill after attaining a certain speed, and the distance it covered during that time, due account being taken of all differences in level. The smallest curve on the line has a radius of 2,000m.; it was therefore not necessary to consider the curvature in the calculations, but very careful measurements of the air resistance were made by means of tubes projected from the cars in the way already described, and in the end a small correction was found necessary in the formula for air resistance, which was altered to $P = \cdot 0052\ V^2$, and the resistance of the cars was found to be equal to the resistance of nine square metres.

In Fig. 7 the final results of the traction resistance of the cars are represented by four curves showing the total resistance for a car weighing 83 tons, the air resistance of a surface of nine square metres being the equivalent of the air resistance of a car, the horse-power required on the level with no wind, and, by the difference of the first and second curves, the resistance due to mechanical friction. It is at once apparent, from this diagram, that at high speeds the air resistance is by far the most important factor, and that the proper shape of the car has to be very carefully determined.

From their experiments the Studiengesellschaft draw the conclusion that the front of the car should be a rather steep paraboloid. Owing to the necessity of arranging the cabin of the driver in front, and providing buffers and drawbars, it is not possible to carry this out in practice, but the nearest approach to the correct form is suggested to be a cylindrical front, extending for 86deg., then plain surfaces which join the sides of the car by easy curves, as represented in Fig. 8. Very careful measurements were made as to the amount of energy required, and a measuring station was established at the feeding point to avoid the calculations of the losses in the feeder. The ammeter and wattmeter at this station were connected direct to the high-tension circuit to avoid the use of transformers, and to make them almost independent of periodicity and of difference in phase. In the cars the instruments were joined to

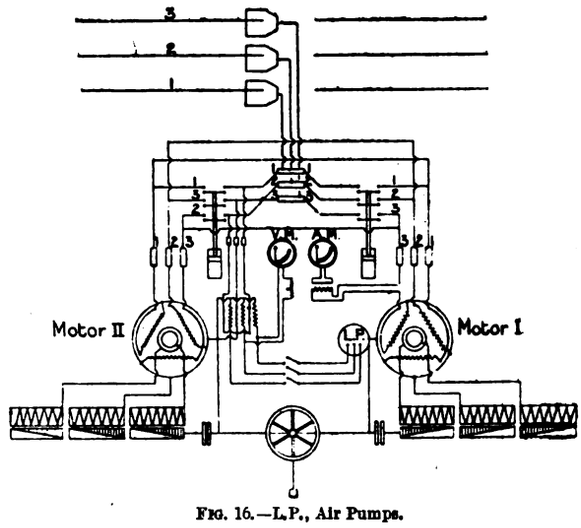

FIG. 16.—L.P., Air Pumps.

the same phase as the feeding point. In spite of all precautions, however, the readings were not all reliable, especially in wet weather. The measurements are divided into two groups: one to determine the energy during acceleration, and the other to measure it at constant speed. In both cases the cars were sometimes running by themselves, and sometimes pulling trailing cars. It will be noticed that the acceleration is not very great, but this was the consequence of the generating set not being powerful enough to supply more energy. Compared with the theoretical amount of energy required to give the cars the same acceleration, the figures of the table show an efficiency of about 45 per cent., due, no doubt, to the losses in the starting resistances; but for long-distance travelling the period of acceleration is almost negligible.

In Tables A and B of Fig. 9 the results of these experiments are summarised, and diagrams in Figs. 10, 11, and 12 give some details of runs and without trailers. An attempt was made to measure the turning moment of a motor direct by fitting on car "A" a special apparatus represented in Fig. 13. Instead of attaching the motor rigidly to the frame, it is held by springs, as shown diagrammatically, and the movement of the springs is transmitted by suitable levers to a registering indicator in the interior of the car. The instrument was calibrated by weights, and gave useful results when a resistance was inserted in the secondary circuit of the motor; but, of course, the direct comparison.

Digitized by Google

between the indicated turning moment and the electrical readings is thereby prevented. Diagram V., Fig. 14, shows the turning moment during a run of car "A" on Nov. 8, and the curve below it is drawn in accordance with these indications. About the measurements made to ascertain the loss in feeders and conductors, nothing need be said, as no novel features with regard to them are disclosed in the report. Nor need the brake experiments be described, as they were again unsatisfactory, and eventually it was considered advisable to alter the whole of the braking arrangements. A good opportunity for doing this was afforded by the reconstruction of the bogies, which became necessary to ensure the steady running of the cars during high speeds. In the new bogies the following points were to be observed: (1) the wheel base is to be increased from 3·8m. to 5·0m.; (2) the bogie frames are to be constructed with simple Z girders; (3) the bearing springs are to be connected by balancing levers, and are to be visible and easily accessible throughout their whole length; (4) the car body is to be supported at four points on each bogie; (5) the centre pin of the bogie is to be movable for a distance of 30mm. in every direction; (6) the motors are to be connected to the axles by springs; (7) the brakes are to be reconstructed as shown in outline by Fig. 15, which explains itself.

During the trials the bending of the rails was measured in the same way as in the previous year; but as the speed of the cars had been restricted, no abnormal observations occurred and no extraordinary repairs became necessary.

When the trial runs of the high-speed cars had been completed, some further experiments were made with a three-phase locomotive built by Messrs. Siemens and Halske, and the Studiengesellschaft comments on them in a separate report. In this case they say that the high-speed cars have proved suitable for their work as far as their mechanical and electrical outfit is concerned, but their weight is too great and the proportion of their dead weight to the paying load is not favourable. The trouble with the permanent way and the very high power required during the acceleration period were a consequence of this weight, and for economical high-speed traffic it should, if possible, be diminished so as to load the axles only sufficiently for the necessary adhesion. It would not be possible to effect this object by altering the construction of the car or by lightening its mechanical outfit without endangering its safety. It is therefore necessary to try to diminish the weight of the electrical apparatus. This may be done by removing the transformers from the car and placing them along the line, or by dispensing with them altogether. In the first case a double set of conductors is required, increasing the losses and the capital expenditure. It is, therefore, preferable to employ motors which are capable of utilising high-tension currents.

With a view of trying the possibility of using such motors on the high-speed cars, Messrs. Siemens and Halske built two motors of approximately the same outside dimensions, but suitable for working with 10,000-volt currents, and fitted them each to a four-wheeled bogie with a wheel base of 3·25m. The car body, 12·5m. long, is of the usual shape for electric locomotives, and in its centre is a driver's cabin 4m. long by 2·8m. wide by 2·3m. high. In the iron boxes on either side of it are the starting switches and resistances, and on the top it carries the collecting gear, which is like that of car "S." The motors are suspended from the bogie frames after the manner of tram motors, driving the axles by a gearing of 1 : 2. Between the car body and the wheels are two sets of springs, and provision is made for a slight lateral movement relative to the bogie.

The diagram (in Fig. 16) of the connections shows that there are separate switches, moved by compressed air, for each direction of running, a small transformer to supply low-tension current to the air-pump motor, and mechanical switches for the resistances, which are actuated by a hand-wheel in the driver's cabin, geared to a horizontal shaft. Some difficulties were experienced in obtaining readings of the measuring instruments on the locomotive of sufficient accuracy, so that finally only the measurements at the feeding point were taken into consideration. The trial runs were started on June 23, 1902, with 7,250 volts, and this voltage was gradually raised until the locomotive successfully pulled a trailer on June 26 with just over 10,000 volts.

Some of the details of the measurements taken during these runs are given in the accompanying table (Fig. 17). It is at once apparent that the efficiency of the locomotive is much greater than that of the cars at the trials in 1901, for the reason that its motors were working nearer to their rated output. Another reason is the absence of a transformer, so that a comparison at an output of 400 h.p. shows that the locomotive required for this at 10,800 volts, and cos $\phi = 0\,85$, an average current of 19 amperes, while the cars at 6,300 volts and cos $\phi = 0\,5$ consumed about 53 amperes. The losses in the conductors along the line are, therefore, 2 kw. in the case of the locomotive and 17 kw. in the case of the cars.

In conclusion, the report considers that the trials have proved the possibility of building motors for three-phase currents of 10,000 volts, used direct without transformers. It is mentioned that the motors and the gearing have worked without giving any trouble.

COMMUTATION OF CONTINUOUS-CURRENT GENERATORS AND MOTORS.*

BY G. A. NEILD AND P. E. BANTING, MEMBERS.

Note.—Where the term "leading pole-tip" is used in this paper, it means the tip which is last to leave a given coil as the armature rotates, whereas the leading tip is the one which meets the coil first. Where the term "central point" is used as regards brush position, it means the geometrical centre between the poles, while "neutral point" means the point of neutral field, which may vary with armature reaction.

As this is such a large subject, it has been decided to deal only with machines having slot-wound armatures and carbon brushes. Before going further, it may be well to draw attention to Fig. 1, which shows diagrammatically the

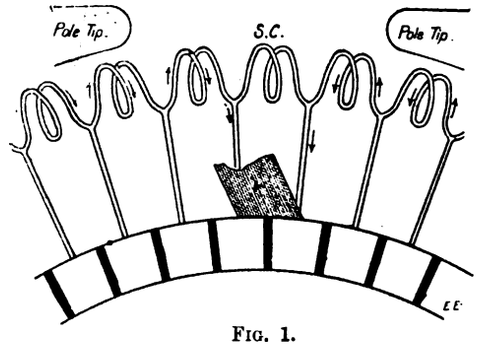

FIG. 1.

actual flow of current in the armature winding of an old-type Gramme-wound machine. This type has been chosen as being the simplest form of armature winding to illustrate the winding. Suppose the positive brush to be the one shown in the figure, the negative being at the bottom of the commutator, it will be seen that the current flows in an upward direction under each pole, out at the top brush, round the circuit, and in through the bottom brush. It will also be observed that the coil shown opposite the brush is short-circuited, having theoretically no current flowing in it. This short-circuited coil, when it leaves the brush, will then be ready to take a current which flows in the opposite direction to that which was last travelling through it.

The principal reason for using carbon brushes on modern machines is that the resistance of these per square inch is from five to ten times that of copper, according to the quality of carbon used. The effect of this high resistance on commutation is as follows: As the commutator bar leaves the brush the area of the contact of the latter grows gradually less, thereby increasing the resistance. With a copper brush the difference in the resistance of a contact, say, $\frac{1}{4}$in. wide by 4in. long and a contact $\frac{1}{16}$in. wide by 4in. long is comparatively little (the resistance is about

* Paper read before the Rugby Engineering Society.

Digitized by Google

·003 ohm in the first case and about ·012 ohm in the second case), whereas with a carbon brush the resistance of contacts of the same area as mentioned would be about ·03 ohm in the first case and ·12 ohm in the second; thus it will be seen that the difference between the resistances of the large and small contacts of the copper brush is ·009 ohm, while with a carbon brush it is ·09 ohm—namely, 10 times as great.

From the above it will be seen that when a bar is on the point of breaking contact with the brush, in the case of the copper brush there will be a comparatively low resistance for the current to pass through, allowing a large number of amperes to flow; whereas if the same area of carbon brush were in contact with the plate, the resistance, being very much higher, would choke the current down gradually, inducing it to go through the next coil to get to the brush rather than arc across, forming a spark. The use of carbon brushes also facilitates using reversible motors, as it would be, of course, impossible to run a machine against the brushes if copper gauze or stencil copper were used.

In order to obtain sparkless commutation, one of the most elementary things to consider is the position of the brushes, as it is important that these should always be on the neutral point, so that as a given coil leaves the brush it enters a field of the right direction to reverse the current (see Fig. 1). This neutral point varies with the load on account of the armature reaction, which distorts the magnetic field, as shown in Fig. 2. The neutral point on a generator at full load is somewhat in front of the centre line between the pole-tips in the direction in which the machine rotates, and is slightly behind this line in a motor, the tendency in the first case being to saturate up the trailing tip and in the last case to saturate up the leading tip. The higher the armature reaction and

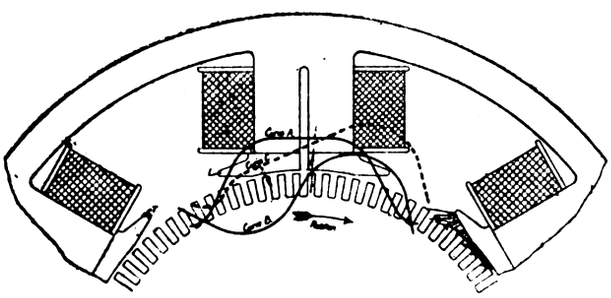

FIG. 2.

the smaller the air-gap in the machine, the greater this effect will be. The correct proportions of armature ampere-turns to field ampere-turns is dealt with under the heading of "Machines with weak fields."

In most modern specifications engineers specify that the machine must be sparkless with the brushes in a fixed position, no matter what the load. In order to obtain this, it is necessary to make the neutral point, as nearly as possible, stationary for all loads. This means that the effect of armature reaction must be reduced. Some makers endeavour to attain this end by means of making a slot from ¾in. to 1in. wide up the centre of the pole, parallel to the armature shaft, the idea being to put a magnetic resistance in the path of the flux due to armature ampere-turns, in the form of an air-gap and saturation of one side of the magnet pole, thereby choking down the effect (see Fig. 2). Another method employed by some makers is to put a divided pole shoe on the bottom of the pole. This shoe is made half of cast steel or wrought iron, the other half being of cast iron, the latter constituting the trailing tip. The cast iron, of course, gets highly saturated very easily, and prevents any more magnetic lines being forced through in that direction when the load comes on the machine. It is also occasionally the practice to make the leading pole-tip of a generator longer than the trailing pole-tip, which gives a good magnetic field as the coil leaves the brush, as well as tending to rectify distortion. Both these last methods prevent the machine from being reversible.

Theoretically, the armature coils, which are being short-circuited by the brush, should be in an absolutely neutral field, and each should enter a field which tends to reverse the direction of the current in it as the bar to which it is connected leaves the brush; therefore, the proportion which the pole arc bears towards the distance between the pole-tips is also of importance. If the pole-tips are too close together, the magnetic lines from one cross over those from the other (see Fig. 2), so that there is no real point of "no field." It has been found from experience that the pole arc should be from 66 to 75 per cent. of the total pole pitch—probably about 70 per cent. is the best figure for machines with small air-gaps, whereas the lower figure (66 per cent.) is best on machines where a wide air-gap and a heavy chamfer are employed, because if the tips were near together in this case the lines would cross one another, as mentioned above. If the distance is too great between the tips, the coil, as it is about to leave the brush, is not in a sufficiently strong reversing field. In the case of a reversible motor, such as a crane motor, which has to run at the same speed in either direction, it is impossible to have the brushes on the neutral point, as they must be in a geometrically central position, and this never coincides with the neutral point (this matter is considered separately under the heading of "Crane motors.")

While speaking of neutral point, it may be well to see how the width of the brush bears on this. If the brush is too wide and the neutral point is fine, it is probable that sparking will be produced owing to coils being short-circuited which are in a strong magnetic field. This has much the same effect as if a narrower brush were used, which was not on the neutral point. On the other hand, if the brush is too narrow, it will not short-circuit sufficient coils, and a given bar will not have a sufficiently long time in which to pass the brush. As a general rule, the brush should cover about 1½ to 2 bars, if an ordinary winding is employed.

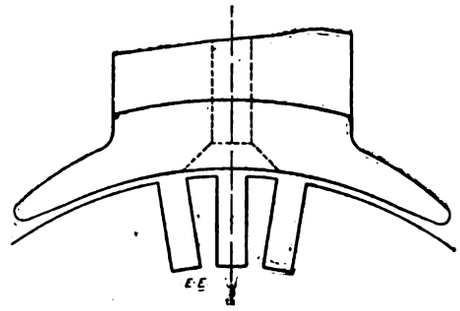

FIG. 3.

In endeavouring to obtain good commutation, care should be taken that the shape of the potential wave is correct. The curve of this wave from the neutral point up to the maximum should not be too sudden. In order to obtain a gradual slope, it is necessary to saturate up the pole-tips, this saturation gradually increasing the nearer you get to the extremity, forming a good fringe of flux, so that the field strength grows as gradually as possible from the neutral point to the maximum. This latter should not be situated too far under the pole face, as the coils should enter a fairly strong field soon after leaving the brush, as has already been explained. Different makers have various methods of saturating up these tips—some of them employing cast steel or laminated wrought iron, and cutting the material down very fine, while others employ cast iron, which, of course, has very much the same effect, owing to its poorer magnetic qualities. When laminated wrought iron is employed, it is sometimes the custom to cut out every other lamination. Not only should the pole-tips be thoroughly saturated, but it is also well to chamfer them back on the face, as shown in Fig. 2. The amount of this chamfering, of course, depends on the width of the air-gap employed, as it is the proportion of chamfer to air-gap which it is necessary to get correct. In actual practice it has been found best to employ long pole-tips, thin at the ends (as shown in Fig. 3), with a slight chamfer at the extremities.

It may be here mentioned that if the iron of the armature core is of an inferior quality—having bad hysteretic qualities—the magnetic lines in the teeth will be apt not to reverse until after passing the central point by some appreciable distance, thereby dragging over the flux from

Digitized by Google

the pole-tip still more than armature reaction alone would cause.

Effect of Weakening the Fields of Dynamos and Motors.

Armature reaction plays a very important part in the design of generators which have to work over a large range of voltage and in variable-speed motors. The ratio of armature ampere-turns to air-gap ampere-turns can be as high as 1 : 1 with machines which have an average width of air-gap, but if the reactance voltage is very low by calculation, and the field strength is practically constant—*i.e.*, no variation in voltage—the armature ampere-turns can be about 20 per cent. higher than is given above. With very small air-gaps, it is not advisable to work the armature ampere-turns higher than 80 per cent. of the air-gap ampere-turns, as the distorting effect on the fields is approximately inversely proportional to the width of the gap. Also, on separately-excited boosters which have to carry their full-load output over a range of voltage varying from, say, 100 volts to 10 volts, the armature ampere-turns should be kept as low as possible to avoid sparking on the low volts when the field is very weak. On self-exciting generators, such as are used for battery charging, the same remarks apply, but in this latter case instability limits the range of voltage possible. In almost all specifications of the present day, an overload of 50 per cent. is required momentarily on all dynamos and motors without brush shifting or sparking at the commutator. Consequently with the same strength of field, but with 50 per cent. more armature ampere-turns, the effect of this latter must not be capable of overpowering the former, or even distorting it to such an extent that it will necessitate shifting the lead of the brushes.

In speaking of the above ratio of armature ampere-turns to air-gap ampere-turns, the authors have taken the calculated air-gap ampere-turns necessary to drive the flux across the gap from the pole-face to the top of the armature teeth, assuming that the density at the pole-face is rather higher than that in the air-gap, due to part of the lines spreading out at the sides as shown in Fig. 2, on the right-hand pole-tip. Variable-speed motors are affected in exactly the same way as generators which have to work over a large range of voltage, and consequently, in designing this type of motor, it is necessary to under-rate the horse-power on the high speeds where the field is weakened by inserting resistance in the shunt circuit. Not long ago a testing motor working on a very weak field to increase its speed for driving a high-speed generator was developing an overload of about 30 per cent.; by accident a further increase of load of about 20 per cent. was put on the generator. The result of this was that the motor pulled up dead, due to the field produced by the armature ampere-turns overpowering the normal field, and tending to run the motor in the opposite direction. On the motor pulling up, a very heavy rush of current naturally passed through it due to the back E.M.F. being reduced to nil, and consequently the circuit breaker came out, saving the armature from burning up.

In dealing with this subject, it may be advisable to point out the advantage of using compound-wound motors on circuits in which the load is very intermittent, or where sudden loads come on at regular intervals. A good example of this last case can be found in small printing presses, in which the printing table is rotated backwards and forwards by means of a crank, this latter being driven by a motor. Every revolution of the crank the motor has to get the crank over its dead point, thereby necessitating a considerable overload on the motor. Now, if a shunt motor is used for this work, there is nothing to check the armature reaction distorting the field on the overload, but if a series winding is placed over the shunt winding, in series with the armature, the flux produced by the field will be increased in approximately the same proportion as the armature reaction. In this way the armature reaction is to a great extent cancelled out. Also, on crane motors it is advisable to use compound-wound motors; in fact, this type of motor should be used in all cases where a fluctuating load occurs. Of course, series-wound motors are better than compound for cancelling out armature reaction, but the objection to these motors is that they cannot be run on light loads, due to the excessive speed.

Reactance Voltage.

Before discussing the actual reactance voltage it is necessary to define the terms "inductance" and "reactance." Any wire carrying current is surrounded by a large number of concentric circles of magnetic lines, which rise and fall with the current; consequently, if the latter is suddenly broken, all these lines will fall back, as it were, on to the conductor, thereby producing an E.M.F. in that conductor opposing the E.M.F. driving the original current. The result of this induced E.M.F. will be to retard the original current, whether falling or rising. Inductance may be defined as the total amount of lines produced round the conductor carrying unit current. If anyone wishes to obtain a practical example of the effect of inductance, the authors would recommend him to break the shunt of a large 500-volt bipolar generator when running with the field fully excited, and then note the result by the respective position of his head and feet. Now take one of the coils of the winding shown in Fig. 1, the inductance expressed in henries = lines surrounding one turn × number of amperes × total number of turns × 10^{-8}. In this figure it will be noted that there are two turns in each coil. The inductance produced in a given coil varies as the square of the number of turns, and consequently it is most necessary to keep the turns per section on any motor or generator as low as possible to reduce the inductance round

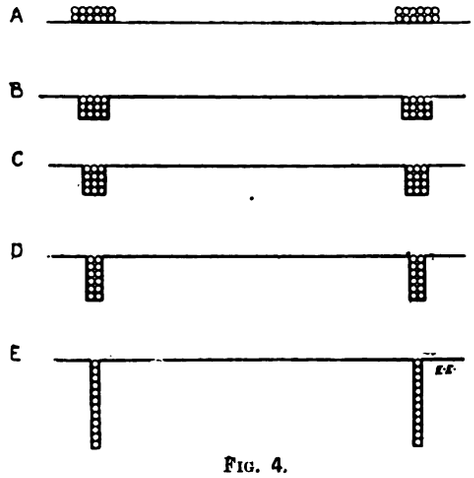

Fig. 4.

the short-circuited coil. On a smooth-core armature the path of the magnetic lines round the conductor lying on the surface of the core consists almost entirely of air, no iron being present except that immediately below the conductor, and even at this point there is usually about $\frac{3}{16}$in. to $\frac{1}{4}$in. of insulation between the iron and the coil; but on a slotted core the path round the conductor consists almost entirely of iron, the insulation between them being only about ·04in. to ·06in. The inductance will depend very considerably on the depth of the slot in the core.

Fig. 4 shows various methods of assembling a given number of conductors, A representing a smooth-core winding, and B to E different types of slot winding. These slot diagrams have been taken from a paper read before the Glasgow Congress in 1901 by Mr. Hobart, in which he refers to some tests made on experimental slots and coils, as shown in this figure. He found that there was a difference in induction between A and E of about 300 per cent., clearly showing the effect of the iron path on the magnetic lines of induction; but with the arrangement shown in B, C, and D there was only a difference of 35 per cent. Between D and E there was a difference of 63 per cent. Although the actual figures of inductance expressed in C.G.S. lines given by Mr. Hobart are very doubtful, the percentage difference in effect is very interesting. The width of slot to depth of slot should not exceed the ratio of 1 : 3. To decrease the lines of inductance circulating round the conductor, it is advisable to work to teeth at as high a density as possible, as the less saturated the iron the better will be the path for the circulation of the magnetic lines. It is not possible to saturate the teeth to

Digitized by Google

any great extent, as this would then increase the resistance of the magnetic circuit, thereby necessitating more ampere-turns, and consequently more field copper on the spools. Another objection to working the teeth at a very high density is that it tends to make the machine hum. The density at the bottom of the teeth should be about 125,000 to 135,000 C.G.S. lines per square inch for ordinary machines, but this figure is usually about 150,000 on series-wound crane and railway motors. Reactance = $2\pi \times$ inductance $\times$ periodicity of commutation. It should be noted that "periodicity of commutation" is quite distinct from the periodicity of the machine. Periodicity of commutation = $\frac{P}{2T}$ cycles per second, where P = peripheral speed of commutator in inches per second; T = thickness of brushes in inches; periodicity of the machine = pairs of poles $\times$ revolutions per second.

On a machine with a large number of poles the commutator is usually of a large diameter to take the necessary number of studs (number of studs = number of poles). The large diameter of commutator will increase the peripheral speed, and consequently the periodicity of commutation. This point is one of the limiting features to the number of poles to be used on a given machine, but, on the other hand, with a larger diameter of commutator, a greater number of commutator plates can be used to reduce the conductors per section. On heavy-current machines a large number of poles is advisable, in order to reduce the amperes to be caried in each brush. The current in any conductor of the armature should not exceed 200 amperes.

Reactance voltage = reactance $\times$ current per conductor. The term "reactance voltage" was first used by Messrs. Parshall and Hobart, and as usually calculated is a purely arbitrary term, but it is extremely useful for comparing the sparking properties of different machines. It is very doubtful what the true "reactance voltage" set up in the short-circuited coil really is, as it is always calculated on the assumption that the fall and rise of the current during the short-circuit follows a true sine wave, but up to the present no experiments have been made to prove this assumption. Various methods have been used for calculating this voltage, all based more or less on the principles referred to above. For instance, Mr. Hobart, in calculating the inductance per coil uses 10 C.G.S. lines per inch length of conductor lying in the slot, and 2 C.G.S. lines per inch length of end connection. These figures may be approximately correct, but so long as the same figures are used in all calculations it does not matter very much whether 10 C.G.S. lines per inch length of conductor are used or whether 20 C.G.S. lines are used, because, as stated above, the reactance voltage is only useful for the sake of comparisons. On small machines up to, say, 50 kw., the reactance voltage should not exceed two volts per coil, but on machines of 200 kw. and upwards this figure can be slightly increased to, say, three to four volts. It does not necessarily follow that if the reactance is very low the machine will operate satisfactorily, as the armature reaction plays a very important part as regards the sparking properties of the machine. This has been gone into fully in a previous part of this paper.

As regards reducing the number of turns per coil, the limiting feature is the number of commutator plates that can be used on a given diameter of commutator. A large number of plates naturally increases the cost of the commutator to a considerable extent. An instance of this may be found in the fact that on a commutator of about 20in. in diameter the cost of labour was increased about 250 per cent. by using approximately 320 plates instead of 200. In all machines having more than two poles it is found advantageous to use series-coupled armatures in order to obtain good commutation, but, of course, there may be reasons to prevent this which have no connection with the matter under discussion. This holds good for machines up to 500 kw. or 600 kw. capacity at least. The chief reason that parallel-coupled armatures are not desirable is that if one pole happens to be stronger than another—due to any inequality of iron or air-gap—the coils under that pole will take less load than the coils under the weaker one, due to more back voltage being generated in them. This, of course, applies to motors. In the case of generators the coils under the weak pole will take current from those under the strong pole, and will tend to act as motors; then, the brushes being in the correct position for running as a generator, this weak pole will gradually become strengthened, owing to armature reaction, until it gets stronger than the one which was originally the strong pole. The action will then be reversed, the coils under the latter pole acting as motors. This will continue until very large currents are being generated, and flowing first one way and then the other, causing violent sparking, which is commonly known as "bucking." Another phenomenon which may be observed, and which is due to the same cause, is the violent vibration which is set up in the machine.

The bucking effect mentioned above may be overcome to a great extent by means of fitting equalising rings at one end of the armature, through which these large currents will play (this is somewhat detrimental to the efficiency of the machine). The common practice is to fit one equalising ring per pair of poles—*i.e.*, an eight-pole machine will have four rings, each of which will be tapped in four places, the connections being joined to the armature winding at equidistant points. The cross-section of these equalising rings should be about half that of the armature conductors. In order to use these to advantage, the number of the slots must be divisible by the number of pairs of poles, as if the tappings are unequally spaced, their use will do more harm than good. In actual practice it has been found useless to employ them on machines of less than 60 kw. capacity, except where the current is very heavy, in which case they may be found to have a good effect down to as low as 30 kw. With a series-coupled or wave-wound armature, the slots should never be divisible by the number of poles for good work; whereas with a parallel-coupled or lap-wound armature they should be so divisible, especially if the slots are few in number. This is the more necessary on account of the danger of having to fit equalising rings, as has already been explained. As a general rule, it will be found best to have as many slots in the armature as is compatible with having a wide and shallow slot, as the greater the sub-division, the less will be the difference between the magnetic field in one slot and the next when passing the neutral point.

With regard to the sub-division of the commutator, it is advisable to go to not more than three commutatator bars per slot, as it is obvious that if there are more than, say, three bars per slot, the coils which are connected to these segments will be in the same magnetic field at the same instant, while the segments themselves will not all be in the same position with regard to the brush. Only one combination of coil and segment can be in the theoretically correct position at a given instant, which necessitates the other two being in an incorrect position. On the other hand, if there are a small number of sections, you will have a great number of turns per section, which, as has been shown above, is detrimental from a reactance point of view.

As regards pitch of the winding, it is best to span from the centre of one pole to the centre of the next. Some makers go from the centre of one pole to one or two slots beyond the centre of the next, so that while one half of the coil is in the neutral field, the other half is just entering a reversing field. On the other hand, some machines are wound with a pitch one slot less than the distance between centres of poles. This last method, however, seems to have a detrimental effect on the efficiency of the machine for some reason, which has not as yet been explained by anyone.

Crane Motors.

As the brushes are set centrally on these machines, in order to obtain the same speed in either direction, the armature coil as it leaves the brush cannot well be in a reversing field (it is probably even in a field of the wrong direction), so that the whole of the reversing action overcoming the ohmic resistance of the coil and the reactance voltage must be produced by the contact resistance of the brush. In the following example a 20-ampere machine has been assumed. Referring to Fig. 5, say the contact resistance of one commutator bar to the brush is ·1 ohm, and say each end bar is one-third covered by the brush—

Digitized by Google

i.e., the resistance of these will be ·3 ohm—then the voltage tending to reverse section A will be 2·9, that tending to reverse section B will be nothing, and in the case of C it will be ·1. If instead of section A carrying one ampere unreversed it carried 10 amperes reversed, the reversing action, instead of being 2·9, would be minus 1, tending to put the 10 amperes back into the original direction. For sparkless running, the reversing voltage should be arranged so as to give 10 amperes in section A when it leaves the brush, no

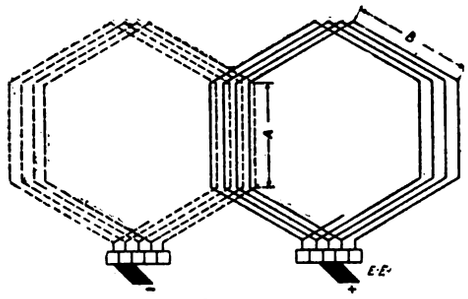

FIG. 5.

more and no less. The fact that one can procure sparkless commutation by giving the brushes a backward lead, shows that the sparking of the brushes when central is due more to too little rather than too much reversing voltage. By curve shown in Fig. 6 it will be seen that most of the reversing appears to take place between the time that the commutator plate begins to leave the brush and the time when it breaks contact altogether. It, therefore, appears to be approximately correct to take half a period as equal

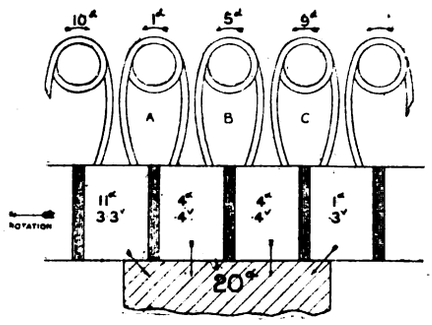

FIG. 6.

to the time taken to pass one section rather than as the time taken to pass the brush.

ERRORS OF CONSTRUCTION.

Under this heading the authors have considered points which do not come directly under design. One of the commonest faults to be met with due to bad construction is the copper and mica sections being of unequal hardness. If the mica happens to be harder than the copper, the latter will wear away more quickly than the former, leaving the mica standing up above the surface of the commutator, which causes the brushes to vibrate violently, therefore causing sparking and pitting of the surface. On the other hand, if the mica

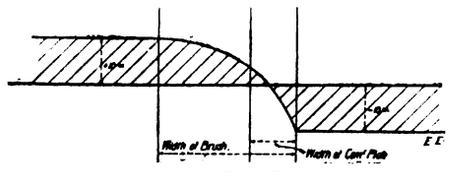

FIG. 7.

is softer than the copper, it will wear away more quickly, leaving grooves which will collect copper dust. This, if allowed to continue for some time, will be apt to short-circuit the segments together. The brush tension to ensure smooth running should not be less than 2lb. per square inch and not more than 3lb., as if it is less than the first figure the brushes will be apt to vibrate, while if it is more than 3lb. per square inch, the friction and wear will be excessive. The best type of brush-holder to use is that in which the carbon is enclosed in a box, being quite free to move up and down, the tension being applied by means of a clock spring pressing on the top of the brush. This clock spring is coiled at the other end, and adjustment is obtained by means of a small handle which passes through the spindle to which the coil is attached. This small handle engages with a ratchet. If the carbon fits the box too tightly, it will be liable to stick, and not follow up the wear properly; whereas if it is too loose, it vibrates and tends to twist over in the direction of rotation of the machine, which prevents its being square to the commutator. As a general rule, radial brushes will be found to give better results than angular ones, especially on reversible machines. If angular brushes are used, the best results will be obtained if the brush-holder is set against the rotation of the machine while the angle of the brush is with the rotation. The brush box should be brought down as near to the surface of the commutator as possible without actually touching it, as it will then hold the brush more firmly if the latter does not fit sufficiently tight. Care should also be taken to see that the brushes are staggered, as otherwise the commutator will very quickly be worn into grooves. Another very common fault in construction to be encountered is the mounting of the brushes on the stud so that they come out of line. When this is the case, it is the same as if a wider brush were employed, as a space is covered equal to the distance from the forward edge of the foremost brush to the back edge of the hindermost.

A few other causes of sparking due to faulty construction may be mentioned as follows—viz.: inequality of air-gap, inequality of iron, unsymmetrical winding, unequal spacing of the brush studs, lack of rigidity in the foundations, engine twisting movement, brushes not being properly bedded. This last is perhaps the commonest of all and the easiest to overcome.

One more point which should be mentioned is a badly-built commutator. If the angle of the clamping rings is not correct, or if the commutator is not bolted up sufficiently tight, the plates will be very apt to rise due to centrifugal force, thereby making the surface very rough. Also, if the commutator is made too long the plates may tend to rise in the middle (even though the ends are tight), and in extreme cases they may fly apart altogether.

In conclusion, the authors thank Mr. Betts for the time and attention that he gave to getting out the sketches and diagrams for this paper.

THE TESTING OF CABLES FOR USE AT VERY HIGH VOLTAGES.

M. Jona, in a paper read before the Milan Electrotechnical Society, considers the question of the testing of high-tension cables. It is usual in low-tension work to test at double the working voltage, but it is questionable whether this rule should hold when dealing with 15,000 or 20,000 volts, for on low-tension work the insulation thicknesses are usually ample, and are decided more on account of mechanical than electrical considerations. Also the break-down voltage rises less quickly than the thickness of insulation. Before breaking down, the dielectric (at least, if it is of an organic nature) is permanently deformed, similarly to a metal strained beyond its elastic limit. The fact that high-tension discharges commence as brush discharges increases the danger of harm to the insulation through the application of excessive test pressures. At very high tensions the dielectric warms up, partly due to dielectric hysteresis, which increases approximately as the square of the voltage, and partly due to the conduction. The conductivity increases rapidly with the temperature—the author states that at 30deg. C. the conductivity of the insulation is some 30 times as great as at 15deg. C.

A conductor of radius r surrounded by a uniform insulation up to a radius R and subjected to an alternating voltage, V, will produce a potential

$$v = V \frac{\log \frac{\rho}{r}}{\log \frac{R}{r}}$$

Digitized by Google

at a radius ρ. Differentiating, and employing ordinary logarithms

$$\frac{dv}{d\rho} = \frac{\cdot 434\ V}{\rho \log \frac{R}{r}}.$$

If all dimensions are given in millimetres, this expression gives the variation of potential per 1mm. of insulation material at a radius ρ, and it shows that the insulation near the conductor is subjected to a far greater strain than the outer layers. It also shows that if r is constant, the resistance of the dielectric close to the conductor only increases as $\log \frac{R}{v}$.

The following cases calculated by the above formula show clearly that thickness of insulation is not in itself any guide, as, if r is reduced, the thickness of insulation may be increased and yet the strain at the surface of the conductor may increase:

r. mm.	R. mm.	Thickness of insulation, mm.	V.	v_r. per mm.	v_R. per mm.
4	10	6	20,000	5,450	2,170
1	10	9	20,000	8,680	860
1	7	6	20,000	10,280	—
2·58	7	4·42	20,000	7,700	—

From numerous tests on insulation materials the author concludes that the best insulations are mica and vulcanised caoutchouc, for which the dielectric rigidity may be taken as about 12,000 volts per millimetre. With a 10mm. diameter conductor for 20,000 volts the thickness of insulation should be 7mm., making R = 17, and causing the insulation surrounding the conductor to stand a strain of 3,750 volts per millimetre, which gives a factor of safety of 3·2.

Applying the formula to the case of a conductor ·1mm. diameter, insulated with a substance which will stand as much as 12,000 volts per millimetre, and to work at 100,000 volts, the result for R is the impossible figure of $10{\cdot}75 \times 10^{70}$. Though the formula shows that such a case would be impossible, it is quite possible that such wires could be safely worked in air without an excessive distance between, but only on account of the luminous discharge which would be present, and which virtually increases the diameter of the wire; thus, if the thickness of this discharge around the wire were 1mm., making the virtual diameter 2·1mm., the radius R would work out at only 2,720mm.

The author gives the results of experiments on a line made up of a number of conductors of different diameters connected in series and suspended in air. This line was subjected to a gradually increasing voltage until the luminous discharge commenced in the different wires successively. The voltages at which this occurred are given below:

Diameter of wire. mm.	Voltage.	Diameter of wire. mm.	Voltage.
·12	12,300	6	106,000
·25	18,200	7·6	127,000
·5	28,000	10	152,000
1·0	42,000	12·5	185,000
2·0	57,000	15	196,000
4·0	81,000	—	—

At 196,000 volts the line viewed in the dark showed a luminous discharge of definite diameter varying with the diameter of the wire. The diameter of this discharge corresponded exactly with that deduced from the above formula, with air as the dielectric.

In conclusion, it is pointed out that when the wire is surrounded by insulations of varying quality, it is quite possible for one or more layers to become pierced without the rest of the insulation breaking down, and the author considers that the voltages at which very high-tension apparatus is tested should only slightly exceed the working voltage, as, otherwise, certain regions of the insulating covering may be fatigued or pierced without any external signs of injury.

Society of Engineers.—An interesting visit was made by the president (Mr. D. B. Butler) and members of the Society of Engineers on Wednesday, Sept. 21, 1904, to the pianoforte factory of Messrs. Broadwood and Sons, Limited, at Stour-road, Old Ford. A description of the electrical plant at these works recently appeared in these columns.

THE RELATIVE DISRUPTIVE EFFECTS OF DIRECT AND ALTERNATE CURRENTS.

The *Zeitschrift für Elektrotechnik* gives a short description of tests carried out by the Compagnie de l'Industrie Electrique on the relative disruptive effects of high-tension direct and alternating currents. The alternating current was obtained from a 75-kw. 50-~ external-pole smooth-cored alternator, having a flat-topped curve with a form factor of only 1·255. The direct-current supply was obtained from three 25,000-volt dynamos of the special type made by the firm, with rotating fields, the machines being coupled in series when required. Their current was not absolutely non-periodic as they only had 96 commutator segments, and this fact as well as flatness of the alternator wave are in favour of the alternating current. Nevertheless, the direct current gave the better results in all cases. The tests were made both in the laboratory and in the open air, and the breakdown voltage in the former case was, on the average, about 1·6 times as great as in the latter.

The nature of the electrodes used had a marked effect on the sparking distance in air, and the results obtained are given in the form of curves for the different electrodes, first with direct current, and then with alternating current. The action at 30,000 and 60,000 volts is shown in the following table:

Electrodes.	30,000 volts D.C. distance. mm.	30,000 volts A.C. distance. mm.	Ratio.	60,000 volts D.C. distance. mm.	60,000 volts A.C. distance. mm.	Ratio.
Sphere to sphere	10	16	1·6	30·5	76	2·5
Negative point to positive disc.	16	57	2·2	—	148	1·51
Positive point to negative disc	26			98		
Disc to sphere	14	34	2·4	63	117	1·85

Tests were next made on glass and porcelain insulators, the voltage being increased in each case until a short-circuit occurred between the wire and the iron support, though the insulator was seldom actually pierced:

Type of insulator.	A	B	C	D	E
Breakdown voltage with direct current	24,000	34,000	40,000	45,300	40,800
Ratio of direct-current to alternate-current breakdown voltage	1·6	1·59	1·48	1·35	1·31

Finally, tests were made on 5mm. "carton glacé" (presspahn) and on 20mm. marble, with the following results in the case of the presspahn:

Time of electrification.	Voltage.	Type of current.	Remarks.
90 seconds	9,000	Alternating	—
30 ,,	11,000	,,	Breakdown.
120 ,,	9,000	,,	Strong brush discharge.
15 ,, later	9,000	,,	Breakdown.
120 ,,	10,000	Direct	—
120 ,,	15 000	,,	—
120 ,,	18,000	,,	—
120 ,,	20,000	,,	—
240 ,,	25,000	,,	Breakdown.

The marble plate was broken down after 75 seconds at 20,000 alternating volts, or after 120 seconds at 15,000 alternating volts. With direct current it was only broken down after 15 minutes, when the voltage was increased by 5,000 every two minutes from 10,000 up to 45,000 volts. The only disadvantage in the case of direct current is the fact that certain insulating materials are liable to become electrolysed, but as this can only occur in the presence of water it is not of much importance.

FORTHCOMING EVENTS.

SATURDAY, SEPT. 24.

Municipal and County Engineers (Midland District).—Meeting at Withington, near Manchester.

Robertson Electric Lamp Works.—At 7.30 p.m, football club concert. For programme see other column.

TUESDAY, SEPT. 27.

Municipal Tramways Association.—Annual conference, Liverpool (continued till Sept. 29).

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notices of Meetings, Issues of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had by Order from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	— 6s. 6d.	— 13s. 0d.
Other Places	5s. 6d.	— 10s. 6d.	— 21s. 0d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

AN ANOMALY.

We have called attention to this before, we shall probably call attention to it again, but such is the state of affairs that it is more reasonable to expect the heavens to fall than justice to be done. The Industrial Freedom League is an organisation against which virulent criticisms are launched, many of which may be warranted, but, on the whole, its object is what all must respect. It is "to free private enterprise from undue interference and from rate-aided competition." Its annual report has just been issued, and is interesting reading. The text for our sermon is found on p. 25 of that report, and reads as follows: "I (Hon. Charles H. Lawrence) would like to call your attention to how this enormous (municipal) expenditure affects private enterprise. I am connected with an important industrial concern, the London and North-Western Railway, and I may say that we are almost the largest ratepayers in this country. The unfortunate shareholders of that undertaking are now providing the sum of £600,000 for rates and taxes, or 1½ per cent. on the ordinary dividend due to them. Those who impose the burden of these rates really pay nothing but a very small fraction towards them, and they have very little practical experience of the management of the great undertakings which they are taxing, etc." This part of the indictment will suffice for our purpose. It is true, and it is mildly put. Of late years Englishmen have grown to be talkers, and most decidedly procrastinators, as well as children of Eve, ready to put the evil they do upon the shoulders of someone else. According to our cynicism, there was in olden times a reality in the cry of "fair play." Is there any such reality now, or is not the characteristic degenerated into "God for us all, and the devil take the hindermost"? We also had a maxim mouthed freely, that he who called the tune should be permitted to pay the piper; but who recognises such a thing now? The present style is for one to call the tune and make someone else pay the piper. Surely it is time an industrial freedom league was founded when a railway concern, a factory, or other similar industrial concern is mulcted to the tune of thousands of pounds annually without having a vote or say in the matter. It is perfectly conceivable, and, in fact, occurs in a number of instances, that companies' undertakings pay the major portion of the rates, and has absolutely no power to say a word as to the expenditure. In some cases companies, and especially railway companies, have been heavily hit by the opening of tramways. If these latter were under the same obligations as the railways, there would, perhaps, be little to say in the matter; but they are not. A fundamental difference is that the one has to purchase ofttimes at a heavy price the ground over which its rails go, as well as to construct; the other uses the public road, and has not the liability to purchase the ground over which its rails are placed. When the tramways are controlled by the local authority we may have something of this kind happening. The district may be dependent on the railway enterprise for its original rise and continuance. The railway enterprise was undertaken under the belief that there would be a remunerative local traffic. Had such traffic not been expected, the railway would not have been there. It is rather hard, then, that when the railway has done what it started out to do, the very people whom it started to cater for, and who have benefited by its action, are those who deliberately try to take away the local traffic, not usually by something better than the railway can give, but for other reasons altogether. What with the compounder, the lodger vote, the impotence of companies to have an adequate voice as regards expenditure, the lot of some of these companies is becoming a hard one. Sooner or later

Digitized by Google

retaliation will become a cry, and it will then be seen how inadequate tramways are to replace railways. There is much of the argument put forward by the Industrial Freedom League with which we do not agree, but we are fully in accord with all it does in calling attention to these phases of the anomalous state of the law. We Englishmen pride ourselves upon being a practical nation. The man who invented—or applied, perhaps, is the better way of putting it—the adjective "practical" to this nation must have stretched his imagination to the utmost. It is a nation whose legislative enactments are of the crudest and flimsiest pattern, nine-tenths being a dead letter—a nation where expediency is the unuttered watchword, wherein votes rule, and the old cry of "No taxation without representation" is forgotten.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

MOTOR STARTERS.

SIR,—I should like you, if you can, to put a note in your next issue to correct a slight error which I notice has occurred in the printing of my first diagram, p. 41. For three-phase working the two outside leads of the auto-transformer should be connected together at both generator and motor ends.—Yours, etc., POWER FACTOR.

SIR,—In my answer to Question 715, which appeared last week, the frequency of motor was given as 50. The example was calculated for a frequency of 25.—Yours, etc.,
Sept. 20. X. Y. Z.

SIR,—In your "Questions and Answers" column last week the diagram on p. 42 at the top of the first column is obviously lettered incorrectly. It should read A, C, B, and not A, B, C.—Yours, etc., Y. SAKER.

ARMATURE WINDING.

SIR,—Could any of your readers recommend me a good book, at a reasonable price, for dealing systematically and completely with armature windings for both direct and alternating current generators?—Yours, etc.,

A. B. DUNCALFE.

55, Allen's-road, Ponder's End, Sept. 20, 1904.

LETTERS FROM AN OLD HAND TO A YOUNG ONE.

VIII.—ON GETTING A JOB.

My Dear Young 'Un,—So you are trying for a job! As you say in your letter, "The glories of Collegiate Life have passed away, and left me stranded on the naked earth like Tannhäuser returning from the Halls of Venus. I want a situation!" What a rolling style we have got to be sure. Chuck it

Engineering is a very prosaic thing—though it has its inner music—and if you will accept some practical advice from a matter-of-fact engineer, you will now eliminate any suspicion of highty-flightiness from your character and soberly settle down to about 48 years of hard work. And the first thing you must do is to compose a neat little letter to possible employers stating what you know and leaving out what you only think you know; you will then copy this out in your best handwriting. Your fist has become fearfully bad since you went into College—too much quick note-taking. I don't know why young fellows nowadays think it is beneath them to take writing lessons. They need it—a readable letter sometimes means a job. Typewriting hints at *haut ton*, which is all right for a £300-a-year job, but a little consequential below it. Printed testimonials, for an ordinary job, indicate the professional wanderer. Write a good round hand—not one of those fancy caligraphies that look as if a tipsy spider had been trying to cake-walk and had tripped over itself.

Next, disabuse yourself of the idea that every employer in the electrical industry is gasping to get you. It is well to soak this in at once, as many a young College graduate has begun the weary search for a job with too high an opinion of his market value, the result being a correspondingly heavy disappointment and loss of nerve. Better have a modest idea of yourself, and find it justified. As your position improves, you can improve your self-conceit if you find it necessary.

Now, what are you going in for? Have you the nerve and the stamina to go through the hurly-burly in the shops? Mind you, it is no use playing at work if you are going to be any good. Six o'clock is your hour, not 6.5. Then, hammer and chisel, and, perhaps, a smashed thumb-nail; work in a draughty shop on a shivery cold morning with nothing to warm you but your own exertions and the dismal gas-flare over your bench; work at three o'clock on a broiling summer's afternoon under a glass roof with not a dash of whitewash on it. Breakfast coffee served in a smoky beer-can; rasher of bacon cooked on a piece of scrap iron. One hour for dinner, and then the hot, greasy crush to get through the works gates before the whistle stops blowing. Bovine, mechanical slogging until six o'clock, and then—more work! Work in the evening arranging what you have learnt in the day, reading the technical papers, keeping yourself up to date. Can you stand it?

If you funk it—or, to put it nicely, if your discretionary instincts become predominant—there is still the clerkly career open to you. As you are a smart man, you might, for example, try the Patent Office. It is almost as simple as your pressing the far-famed button, Messrs. Kodak doing the rest. You pass the initial examination (which, by the way, is fairly stiff and competitive), and you have an assured and progressive salary for a lifetime. And a Government job is usually very, very nice, and very, very select. Only sometimes it is very, very slow.

Or a consulting engineer might take you in. I only mean that he might give you employment in his office. Such gentlemen are usually keen on young fellows, effervescing with theory and willing to be badly paid, to take subordinate positions in the office. Only the outlook is not very cheery after four or five years, for there is a great gulf fixed between the underpaid theorist and the practical man who looks after the putting-up of the jobs outside.

Or you may get into the estimating department or drawing office of a manufacturing firm. You will gain useful business experience in the former, and may possibly develop into a designer in the latter department. But you will all the time be handicapped, enfeebled, by the lack of practical experience. An estimator must know the cranks and kinks of the plant he is estimating for. It is no good nowadays putting down £100 extra in your estimate for "contingencies"; things are cut too fine for that. A draughtsman should have the instinct of mass, of strength, that can only be obtained by chipping and filing the stuff. There is always a point in the design which must be settled by rule-of-thumb, and it is the practical man's thumb that is applied—experience is the only sure teacher.

There is one sphere of usefulness which I have purposely not referred to. An Electric Generating station appears to be the Mecca of young technical men. I suppose that nine College electrical men out of ten try for a berth in a lighting station when they graduate; and just that proportion make a big mistake. They are all right in the meter-testing department, and, to a certain extent, on the mains. But in the station they are aliens. They are purely electrical theorists. The electrical machinery entrusted to a shift engineer has about a third of the total value of the running plant. Any part of the remaining two-thirds is just as likely as not going to go wrong at any moment. What will the electrical theorist do then? As a matter of fact, the movement of thought among the station engineers is at present in the direction of putting a marine man, or next to him a glorified fitter, in charge of the plant. This is just because, in an emergency, he can slip off his coat and scrape a main bearing, and because he can go out into the stokehold with an experimental

Digitized by Google

knowledge of the inner working of both the mechanical and human types of stoker. Even if you are going to be a station man, go into the shops first. It will pay you in the end.

I just want to give you a word of warning. Carefully avoid those places which advertise: "A vacancy occurs in an engineering firm for the son of a gentleman as a premium pupil. Thorough knowledge of engineering in all its branches will be obtained. Premium £50." It *may* be all right. I don't like sporting chances myself. There are a lot of twopenny-halfpenny firms run on this kind of cheap labour which are vulgarly known as "pup shops." A moderate quantity of miscellaneous bad work is turned out, and a superannuated foreman, one decent fitter, and one odd-job turner are supposed to do all the fine work and teach a pack of hobbledehoys how not to hurt themselves. Keep off it!

And—I am almost ashamed to mention the matter to a decent fellow—don't try to bribe your way into a post. Of all the things in engineering which are calculated to give one the utter pip I know of nothing worse than the importation into an honourable profession of weak-kneed wasters, who, not having the ability to earn a living fairly, try to wriggle into a place by degrading the honour of people in positions of trust. I cannot conceive that you would do such a dirty thing. But I promise you this—that if ever I were to discover that you had been such a cad as I have described, I would do my level best to ruin you, for your own good and that of the profession.—Yours,

THE OLD 'UN.

MIDDLESBROUGH DOCK ELECTRIC AND HYDRAULIC POWER PLANT.*

BY VINCENT L. RAVEN, MEMBER, CHIEF ASSISTANT MECHANICAL ENGINEER, NORTH-EASTERN RAILWAY.

Now that the question of electric appliances for dock purposes is so generally considered, the author thinks that it may be of interest to record and place before the members of the institution the particulars of the installation and the tests which have been made at Middlesbrough Dock, on the North-Eastern Railway, comparing hydraulic with electric. These are working side by side, and are all thoroughly up to date, giving an excellent opportunity for judging the value of the one against the other, so far as economy in working is concerned. He proposes, therefore, first to describe the machinery at this dock, and then to give the very careful tests which have been carried out. When the dock (Fig. 1) was constructed, it was equipped with steam cranes, and had a small hydraulic power station for working the bridge and gate machinery. Twelve years later, a further extension was made, and hydraulic cranes were then supplied to the new extension. A separate electric lighting station was also put down for dock lighting. With this plant, in the year 1900, the following tonnage was dealt with:

	Tons.
Coal and coke exported	222 616
Merchandise exported	197,933
Merchandise imported	36,941
Ballast worked	1,751
Or a total of	459,241

To do this work

	Coal. Tons	cwt.
The steam cranes burnt	1,989	0
The hydraulic station burnt	994	15
The electric station burnt	932	11
Or a total of	3,916	6

The total merchandise worked per ton of coal burnt was, therefore, 117 tons. When the present extension was proposed, after careful consideration, it was decided to abandon the steam cranes, and to supply their places with electric cranes, and, at the same time, make one large power station, which would supply both the electric power for the cranes and for the lighting, and the hydraulic power water for the hydraulic plant. The work in connection with the power station was divided into two contracts, Messrs. Siemens Bros. and Co, of Woolwich, being responsible for the electrical portion, and Messrs. Carrick and Wardale, of Gateshead-on-Tyne, for the hydraulic installation.

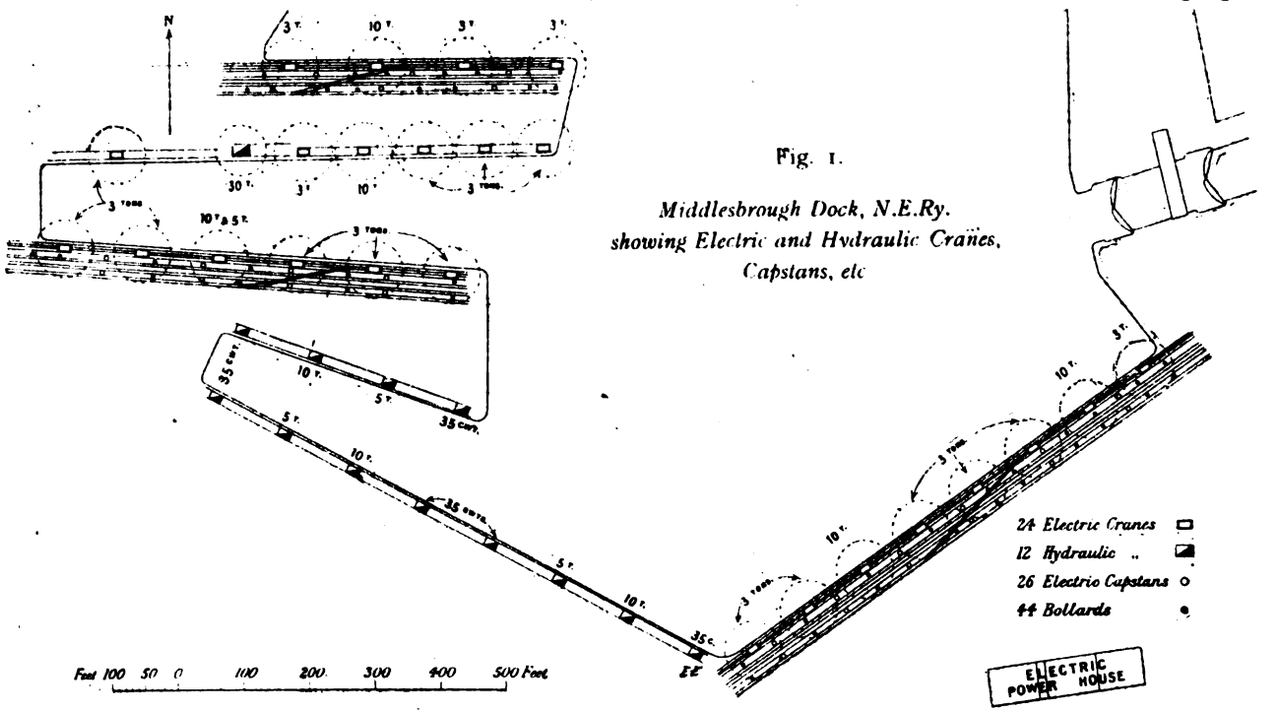

Fig. 1.

Middlesbrough Dock, N.E.Ry. showing Electric and Hydraulic Cranes, Capstans, etc

The power station contains three sets of Messrs. Bellis and Morcom's compound, three-crank, self-lubricating, quick-revolution, vertical engines, discharging with independent condensing plants, each developing 360 b.h.p. at a steam pressure of 150lb. per square inch at a speed of 380 revolutions per minute. These engines are direct coupled to three Siemens dynamos, which have an output of 240 kw. at 430 volts when running at a speed of 380 revolutions per minute. The engines on a six hours' test run gave the following results:

Steam pressure on range	154lb. per square inch.
Steam pressure in steam chest	128lb. per square inch.
Vacuum	24in.
Revolutions per minute	380.
Volts	430.
Amperes	552·5
Exciting amperes	6·75
Kilowatts	237·5
Water consumption	21·1lb. per electric horse-power*
Efficiency	$\frac{318{\cdot}3 \text{ e.h.p.}}{359{\cdot}321 \text{ i.h.p.}\ \dagger} = 88{\cdot}6$ per cent.

* Exclusive of steam used by the condensing plant.
† Exclusive of power abstracted by the condensing plant.

* Paper read before the Institution of Mechanical Engineers, Chicago meeting, 1904.

Digitized by Google

The switchboard is of marble, and consists of four machine and one feeder panel, in addition to the lighting panel. The instruments are of the moving-coil type. The shunt winding of each dynamo is brought to a switch on the board, and these shunt switches are interlocked with their respective main switches, so that it is impossible to break the exciting circuit of any machine until the armature has been cut out of circuit, nor can the armature be thrown in until the shunt circuit is made. The three machines are run in parallel upon the 'bus bars, and the shunt circuits are excited from the bars. The three hydraulic engines are of the triple-expansion surface-condensing inverted vertical marine type. The pressure pumps, three in number, are of the ordinary ram type, worked directly off the piston rods, and each set is capable of delivering 300 gallons per minute at a maximum speed of 240ft., against an accumulator pressure of 800lb. per square inch. Both the hydraulic and electric engines can also be worked non-condensing, and the piping and valves are so arranged that either engine can be changed over

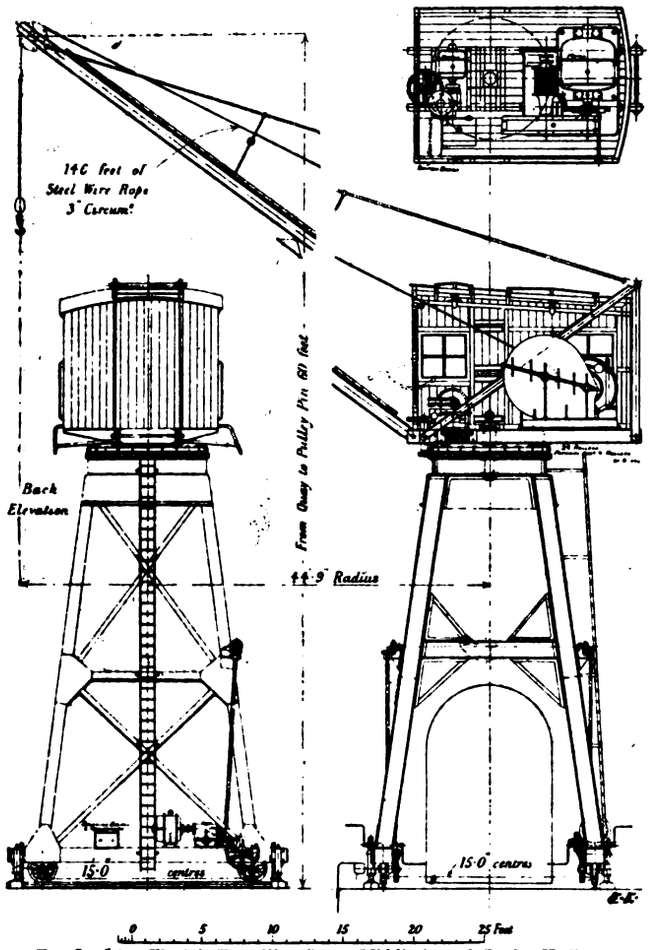

FIG. 2.—3-ton Electric Travelling Crane, Middlesbrough Docks, N. E. Ry.

from condensing to non-condensing, or *vice versâ*, without any stoppage whatever. There are two hydraulic accumulators, 20in. diameter by 23ft. stroke, and situated betwixt these is a large water-tank, which holds 12,000 gallons for supply to the pressure pumps. The hydraulic engines on a six hours' test run gave the following results:

Water pumped at a piston speed of 240ft. per minute		311 gallons.
Water pumped per cwt. of coal burnt		5,090 gallons.
Steam consumption per i.h.p. per hour		14·1lb.*
Total i.h.p.		181·5†
Steam pressure per square inch		150lb.
Vacuum		28·5in.
Efficiency	Pump h.p. / i.h.p. = 162·5 / 181·2	89·5 per cent.
Accumulator pressure		750lb. per square inch.

* Exclusive of the steam used by the circulating pump.
† Exclusive of the power absorbed by the circulating pump.

There are two sets of condensing plant in connection with the electric steam-engines, each capable of dealing with 15,000lb. of steam per hour; these were supplied by Messrs. Carrick and Wardale, of Gateshead-on-Tyne. Each set comprises a compound steam-driven air and circulating pump, together with a surface condenser combined on one bed-plate. The circulating water is passed zigzag through the condenser, and the quantity used is 30 times the amount of steam dealt with, and the vacuum maintained from 27in. to 29in. The circulating water is drawn from the dock, a distance of 300ft., through an 18in. suction pipe, and at low water these pumps have a lift of 15ft., but no difficulty has been experienced in getting the water even at such a great distance. There is also a circulating pump, fitted by the same makers, for supplying water to the condensers of the hydraulic engines, and it is similar in design to the electric plant. The three feed pumps and filters were supplied by Messrs. Henry Watson and Sons, High Bridge Works, Newcastle-on-Tyne.

The boilers for both plants are of the ordinary Lancashire type, six in number, 30ft. long, 8ft. 6in. diameter,

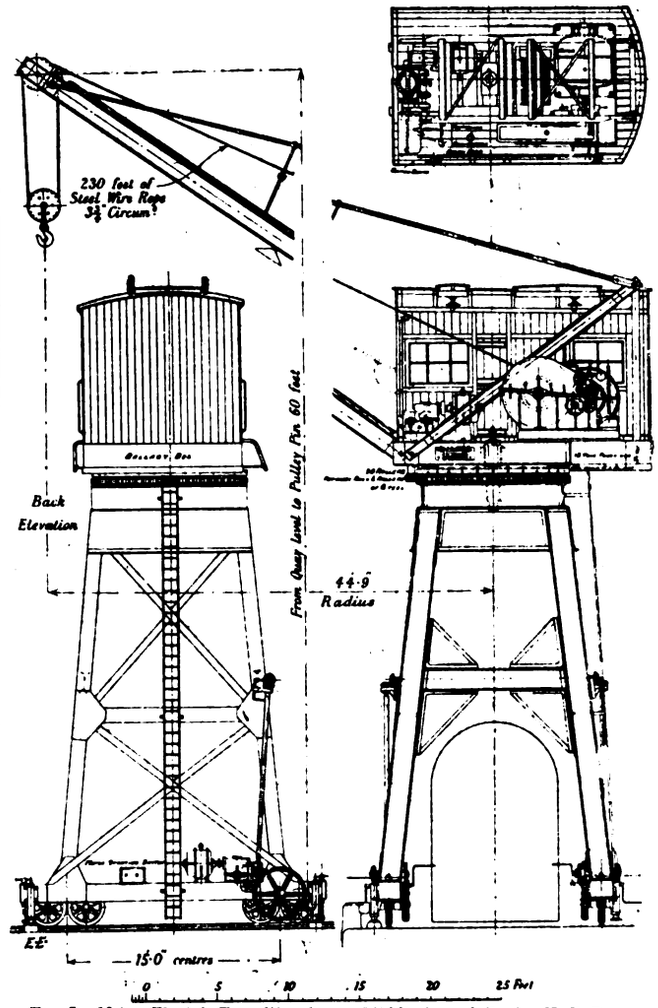

FIG. 3.—10-ton Electric Travelling Crane, Middlesbrough Docks, N. E. Ry.

working pressure 160lb. per square inch, and were made by Messrs. H. and T. Danks, of Netherton. The boilers are fitted with Proctor's shovel stokers, and the coal is supplied thereto by a coal elevator and conveyor supplied by Messrs. Graham, Morton, and Co., of Leeds, the coal in the first instance being raised from ground level in truck by means of a diagonal hydraulic hoist to the top of the coal cells and there discharged. A Green's economiser of 384 tubes, 9ft. long, $4\frac{0}{16}$in. diameter, is fitted in connection with the boilers. The boilers on a six hours' test gave the following results:

Grate area	38 square feet.
Coal burnt	5,208lb.
Clinker and ashes	356lb., or 7 per cent of coal burnt.
Net consumption of combustible	4,852lb.
Combustible burnt per hour	809lb.
Combustible burnt per square foot of grate area per hour	21·3lb.
Pounds of water evaporated	36,300
Pounds of water evaporated per hour	6,050
Pounds of water evaporated per pound of coal burnt	7·5lb.

Digitized by Google

Feed water from hot-well at 110deg. F. was run to waste on account of measuring the water, and town water was put in feed tank at a temperature of 54deg. F., or equal to

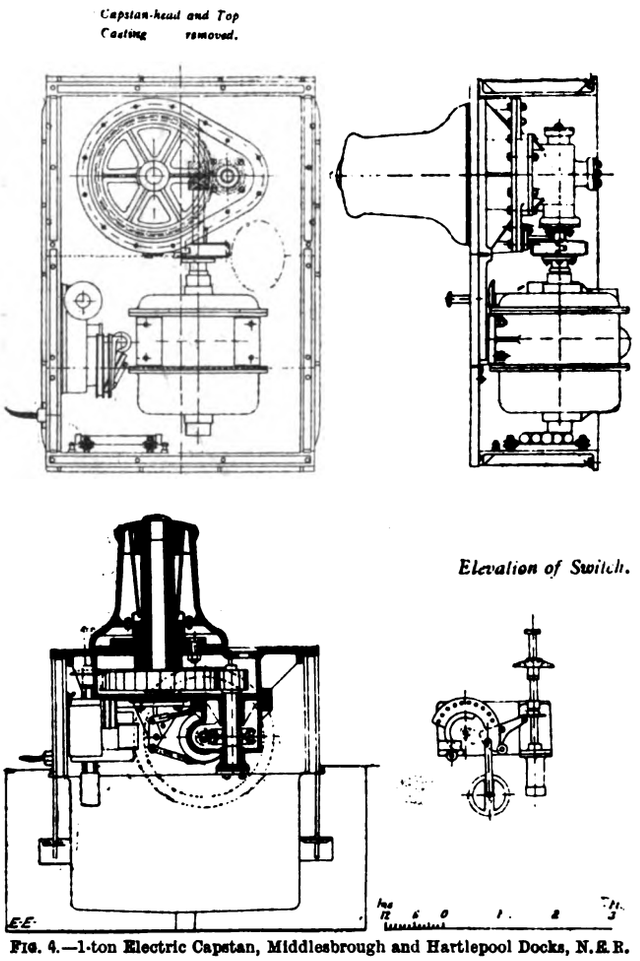

Fig. 4.—1-ton Electric Capstan, Middlesbrough and Hartlepool Docks, N.E.R.

a loss of 241lb. of coal. The steam and hydraulic mains are laid in circuit in the engine and boiler houses respectively. The contract for the electric cranes and capstans consisted of 19 three-ton and five 10-ton cranes (Figs. 2 and 3), and 26 one-ton pull capstans (Fig. 4). The whole of the electrical equipment for these was supplied under sub-contract by Messrs. Siemens Bros. and Co., of Woolwich. The following are the principal particulars of the three-ton cranes (Fig. 2) as specified.

Height of jib top pin from quay level	60ft.
Radius of jib	44ft. 9in.
Speed of lift, three-ton load	150ft. per minute
Speed of lift, 1½-ton load	250ft. per minute
Revolving speed at hook	400ft. per minute
Travelling speed	30ft. per minute
Lifting motor, 50 b.h.p.	300 revs. per minute
Revolving motor, 8 b.h.p.	1,000 revs. per minute

The cranes are of the high gantry type, with gantry 30ft. high, and so constructed as to admit of the passage of wagons and engines underneath. The whole structure is rigidly tied together. Holding-down clips for fixing to the rails and screw-down jacks for increasing the base when the maximum load is being dealt with are also provided, but the cranes are absolutely stable, even with a 50 per cent. overload, without these attachments. The travelling gear motion is fitted with both hand and electrical gear, the latter consisting of an enclosed series-wound multipolar motor, which is coupled to a steel worm working into a delta metal worm-wheel. The power is communicated to the trod-wheels by means of spur and bevel gearing, the wheels on each side being coupled together by means of a cross shaft, thereby ensuring uniformity of movement and avoiding any twisting strain on the gantry. The switchgear for the travelling motor is placed in a watertight case upon the bottom framing of the gantry. To prevent the possibility of unauthorised persons starting the gear, the switch is provided with a detachable key, which is kept in the charge of the crane-driver. The top framing is constructed of H beams riveted up into box shape and carrying the heavy plate which takes the roller path. H-beam cross-stays take the thrust and stiffen the structure. The roller path and rack are of cast steel; they are not bolted to the top plate, and whilst they are held down by a groove turned out of the latter, they admit of some movement and ease the crane in case of a sudden stop when revolving. The rollers are 24 in number and of cast steel. The collector is fitted to the centre pillar, through which the mains are passed and attached to (and consists of) two copper rings mounted upon ambroin and separated by rings of the same material. The collecting brushes consist of two gauze straps, each encircling one ring, the tension being regulated by springs. These straps are attached to terminals, which in turn are mounted upon porcelain insulators, from which the cables for the wiring of the cranes are taken. The

crane cabin is of teak, and the front consists of a wrought-iron framing, glazed to enable the driver to have full view of his load throughout the operation. The cabin contains the lifting and sluing gear and the controlling apparatus. The lifting gear consists of a barrel, wheel, and pinion. The wrought steel pinion is cut from a blank forged solid with the shaft, which is fitted with a half-coupling to meet that upon the motor spindle. Upon this shaft there is a band brake, actuated by an electromagnet which will be described later. The pinion gears into a cast-iron spur wheel keyed on the barrel shaft. Both pinion and wheel have machine-cut teeth, and work in a cast-iron gear case, which forms an oil-bath. The revolving gear consists of a

motor, worm, worm-wheel and spur gear. The worm is cut from a blank forged solid with the shaft, which in turn is fitted with a coupling to meet the motor. The worm engages with a delta metal worm-wheel, and a pinion keyed to the worm-wheel shaft engages with a spur wheel which is fitted to a short shaft actuating a pinion. This pinion travels round the rack of the crane and thus slues the cabin and jib. A brake actuated by a foot-treadle is fitted to the first-motion spindle, so that the sluing motion is always under control. The sluing motor is of similar type to the lifting.

The electric brake magnet, referred to previously, offers some points of interest. It is placed in series with the armature of the lifting motor, and consists of a horseshoe magnet (with poles arranged as those of a two-pole dynamo) with a solid steel armature of special shape capable of revolving between them. The passing of the current round the field coils tends to move the armature through a right angle. A lever is fixed to the end of the armature, and the brake, which is normally held on to the brake wheel by a weight, is connected thereto by a rod. The movement of the armature lifts the brake and releases the brake wheel. The great advantage of the particular form of magnet described lies in the strong pull and long range which it affords. The brake is also connected to a lever which stands

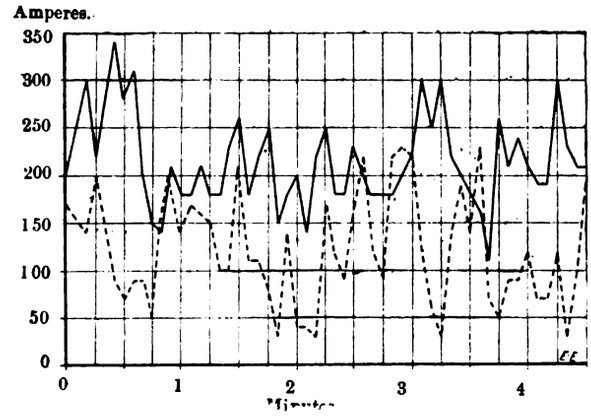

Fig. 8.—Electric Engine Current Diagram, May 31, 1903. Dotted line shows variations in the current load during the working of light loads. Full line, variation in the current load during the working of heavy loads.

at the driver's left, so that it can be operated instantly by hand when necessary. The controller is of the so-called Universal type, and consists of two separate controllers combined in one case and actuated by one handle. One controller actuates the lifting and the other the sluing, and both are connected by pinions and quadrants to the lever. The latter is so arranged, by means of a Universal device, that when moved in a vertical plane it actuates the lifting, and, in a horizontal plane, the sluing controller. Thus it will be seen that the hook follows the motion of the driver's hand, lifting when he raises the lever, and so on. One

Digitized by Google

conspicuous point about the controller is the ease with which it is manipulated, owing to the absence of click gear upon the immediate contacts. Notches are provided only at the two extremes and the off positions, and in consequence the controller may be operated throughout the day without fatigue and its attendant slackness. The resistances are fixed inside the cabin. The switchboard consists of polished slate, framed in teak and fitted with main D.P. switch and automatic cut-out in lifting circuit, and isolating switches in sluing circuit, fuses, and lighting switches. The crane cabin is well lighted by fixed and portable lamps, and a cluster in an enamelled iron reflector is fixed beneath the jib half-way up its length. Terminals are provided upon the switchboard, to which may be connected an inspection voltmeter and ammeter.

Each three-ton crane on being completed was tested in the following manner. A large iron tub (fitted with a valve at the bottom), weighing one ton net, brought close to the quay wall, lowered into the dock, filled through the valve, there being a port in the side of the tub so that the weight of water could not exceed two tons, or a total load of three tons. This was lifted 30ft., and slued through a half circle simultaneously, then lowered on to the quay, where the valve on the bottom of the tank opened, and the water returned into the dock. The tub was again lifted empty, taken back, and the same process continued. Each crane was worked in this manner for three hours, making on an average 100 lifts in the stated time. The current used was, lifting 18·3 and sluing 6·4 Board of Trade units, or a total of 24·7 Board of Trade units, or 2·74 Board of Trade units per 1,000 foot-tons, or a total cost of 5·4d. per 1,000 foot-tons, as shown in the Table No. 2 of costs.

The 10-ton cranes (Fig. 3) are of the same design as the three-ton cranes. The revolving motor is 12 b.h.p. at 1,000 revolutions per minute, and the lifting motor, which is of 60 b.h.p., in single gear, drives directly through a pinion on to the barrel shaft, the ratio of gearing being 8 to 1, and a double part of rope is used. The double gear gives a multiplying power of 20 to 1. With the single gear loads up to two tons are lifted, and the double gear is used for loads from two to ten tons. As it was impossible to get both the hydraulic and the electric cranes working together under similar conditions into a vessel, on account of the cargoes at Middlesbrough being of such a varied nature and the vessels differing so much in dimensions, to obtain comparative figures as to the cost of the work done, a special test was made, which was considered to be the nearest approach to the actual working conditions in loading cargo into a vessel's hold, and the tabulated form shows work done and the power required. The first load was two tons lifted through a height of 20ft. by the single gear, slued through 180deg., and then lowered 20ft.; the light chain hoisted 20ft., and the crane slued back through 180deg. This cycle of evolutions was performed five times. The load was then increased a further two tons each time up to and including 10 tons, and the same number of evolutions made with each load as in the first case, but double gear being used for the lifting. The total current used being 8·1525 Board of Trade units, or 2·717 per 1,000 foot-tons, at a cost of 5·4d. per 1,000 foot-tons, equivalent to 358,710 foot-pounds of energy per minute for the total work.

The author does not propose to take up the members time by going fully into the details of the hydraulic crane, as this is so well known, but simply content himself by stating that it was of up-to-date design, as shown in accompanying drawing (Fig. 6), with a capacity of 10 tons, and having three vertical cylinders for lifting. Water is admitted to the centre cylinder for the light power, the two outside cylinders for the second power, and all three cylinders for the full load. The sluing is done by gearing driven by a small ordinary four-cylinder capstan engine, and the working pressure at the crane during the test was 700lb. The hydraulic cranes are 15 years old, but are all of exactly the same design as supplied by the same firm at the present day, and were overhauled and in perfect condition before the trials were made; and the capstan is quite modern. The power water was measured by means of two Kent's high-pressure water-meters, one on the lifting and the other on the revolving motion, and the crane was worked at its ordinary speed. Precisely the same evolutions were carried out as in the case of the electric crane, and the total gallons of pressure water used was 2,391, equivalent to a cost of 10·25d. per 1,000 foot-tons lifted, or equivalent to 687,412 foot-pounds of energy per minute for the total work.

Another test was made on a Sunday with six hydraulic cranes arranged to be as near as possible on one quay, and water-meters were attached to each crane. Wagons of rails were brought underneath the cranes and worked as if they had been ordinary cargo into a ship. They were lifted to a height of 20ft. slued half-circle, lowered down to empty wagons, the light chain lifted a height of 20ft., revolved through half circle, and lowered down again. Six hundred tons were dealt with as constant loads, and 600 tons as variable loads, and the tabulated statement shows the cost of handling the same. The cost of power per 1,000 foot-tons of work was 1s. 6d., the time occupied seven hours, as shown in Table 1 of hydraulic costs. The same work was done on the following Sunday by the electric cranes, and the cost per 1,000 foot-tons was 1s. 2·23d., and the time occupied 5¼ hours. (See Table 2). The total saving effected by the electric cranes, including cranemen and labourers, was 25 per cent., but the load factor for the electric was only 7·3 per cent., as against the hydraulic 14·4 per cent., so that if more cranes had been working, and a better load on at the power station, better results would have been obtained for the electric cranes. He would estimate that the total gain would have been 50 per cent. The diagrams, Figs. 7 and 8, show the fluctuations of the work.

Capstans.—The electric capstans (Fig. 4) are 24 b.h.p. at 100 revolutions per minute, and are capable of exerting a steady pull of one ton at a speed of 200ft. per minute, or of hauling a load of 100 tons along a level road. The capstan head is driven by a cast-iron spur wheel, which is engaged with a steel pinion. The latter is keyed on the same shaft as the brass worm-wheel. The driving worm is cut from a blank forged solid with its shaft, and is coupled direct to the motor spindle. The worm and wheel work in an oil-bath. The motor runs at 1,000 revolutions per minute, and is completely enclosed. In construction and design it is similar to the crane motors, but is shunt wound to avoid large variations in speed of the capstan head. Upon the motor shaft there is fixed an automatic mechanical brake, the principle of which provides that when the capstan head is driven by the motor the break releases itself automatically, but should the capstan tend to run back through being overhauled by the weight, the brake at once locks itself and sustains the load. Such a brake is absolutely necessary upon an electric capstan, as the latter differs from a hydraulic capstan in one important respect—namely, that in the hydraulic capstan the water in the cylinders holds the load, whereas in the electric capstan there is nothing to sustain the load upon the current being cut off, and if the load is allowed to run back a serious accident may ensue. It is also essential that the brake should be automatic, so as to claim none of the driver's attention from his work.

(To be continued.)

POWER CONSUMPTION ON ELECTRIC TRAMWAYS.

The *Elektrotechnischer Anzeiger* gives a summary of 47 replies from tramway companies to a circular sent out recently by the International Tramway and Railway Verein on the above subject. The figures obtainable from the various replies differ widely. Thus, converting to English equivalents, the lowest consumption per car mile is 560 watt-hours, whilst the maximum value is 1,500 watt-hours. Even the figures per ton-mile vary between 80 and 168 watt-hours. These wide differences result partly from differences in the methods of computing the figures sent in and partly from essential differences, such as the question of gradients and curves, the distance between stopping places, the adoption of special types of motor and trailer cars in some cases, and also the variations in road condition through the frequency or otherwise of rain and snow storms in the different districts. In some cases, also, the current used in the station workshops and

Digitized by Google

lighting has not been subtracted. All these points, of course, greatly affect the consumption, so that it is impossible to decide definitely from the replies that any one tramway is more economically worked than another, but the wide variations naturally lead to the question whether further economies are not possible in many cases. Very few of the companies are of the opinion that such economies are impossible, and most of them hope, by increased efforts, to produce a further reduction in their current consumptions. Various methods of accomplishing this are suggested. Some expect to produce a saving merely by systematic training of the drivers and inspectors; others by the introduction of the three-wire system, the distribution of bonuses, etc. A fair proportion have gone so far as to instal meters on the cars, in order to keep account of the consumptions of the different drivers, and this, so far, has led to satisfactory results. It is satisfactory to note that the different companies agree as the reliability of the meters employed. These are obtained from various firms, and differ in price from £3. 12s. to £15. 15s. each. The meters are usually fitted under the seats, but sometimes they are fixed to the inside walls of the car, or even under the car. The frequency with which the meters are tested varies from once every four weeks to once every four months, and the inaccuracies discovered do not exceed ± 10 per cent. The meters are sometimes read once a day, and sometimes after each journey, or at the end of each driver's shift. Up to the present none of the companies have distributed a bonus on the strength of the meter reading, though several consider it desirable. The general opinion would seem to be that better results are obtainable by a mechanical control of the drivers, such as that offered by the meter system, combined with the distribution of premiums, so as to give the drivers more interest in the work than would be possible simply by the careful training of the drivers and inspectors. Of course, such a system of control involves considerable expense in time and trouble, but the resulting reduction in current consumption would more than balance this, whilst at the same time it tends to produce a *personnel* interested in the advancement of the line.

THE COMMONWEALTH TURBINE ACCIDENT.

Our contemporary *Power* gives the following account of an interesting accident:

On June 18 the three-phase system of the Commonwealth Electric Company of Chicago ran away, and the alternator on one of the turbines was damaged. The conditions before the accident were these: Two turbine-generators of 5,000 kw. each at the Fisk-street station were running in parallel, and supplying a number of rotary converters with three-phase current, which in turn were feeding a low-tension direct-current system. This direct-current system was also being fed by storage batteries and by direct-current generators. It appears that some weeks before this time one of the alternators had been damaged by being thrown on to a line considerably out of step, but the damage had been repaired. This may or may not have had anything to do with the trouble on the day in question.

Fig. 1 is a diagrammatical representation showing the features which it is necessary to consider in order to fully understand just what happened, and what combination of circumstances caused the accident: 2 and 3 are steam turbine alternators; *a b c* represent three of the rotaries being fed from these alternators by three-phase 25-cycle 6,600-volt current; *d* and *e* are two of the direct-current generators feeding the same low-tension system as the rotaries; *f* is one of the several storage batteries also feeding the system. Transformers, switches, neutrals, etc., are left out in the diagram as not necessary of representation in this case. The fields of both alternators were excited, as is shown, from the same source, only one of whose dynamos is represented. Now the first thing that happened that bears directly on the runaway was a short-circuit between the armature coils of No. 2 alternator—this is the alternator that had been previously injured and repaired. The armature on this machine is stationary and the fields revolve inside of it on a vertical shaft. As soon as the attendant noticed the short-circuit, he opened the switches at A, disconnecting the burning part from the alternating-current system. This cleared the armature, but he neglected to open the switches at B clearing the field of the alternator from the exciter 'bus. In the meantime the short-circuit had burned away the binding wires, which in turn caused a ground on the revolving fields. The exciter units now having to pump current into this ground, dropped in voltage, so that the exciting current of No. 3 alternator dropped very low.

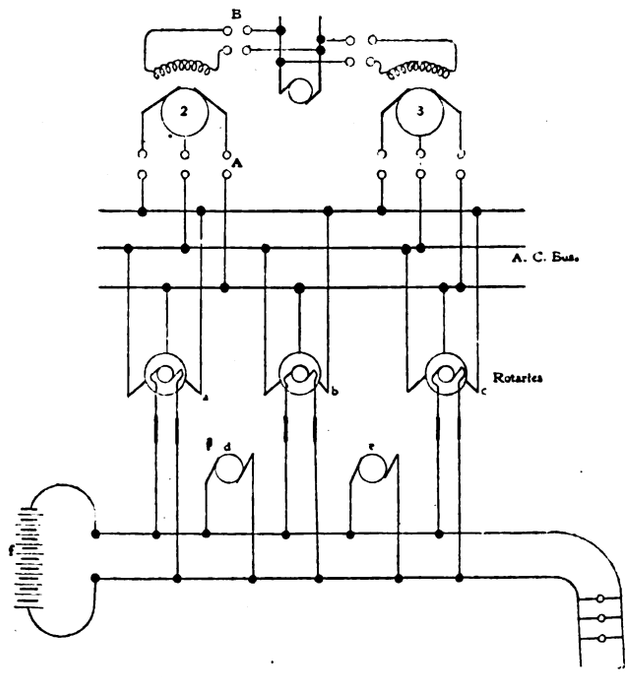

FIG. 1.

The conditions at this stage were as follows: One alternator with a very weak field tied to several rotaries which are feeding a direct-current system, and this system being also fed by generators and batteries. Now, the alternator being left alone on the line after No. 2 was cut out, would be greatly overloaded, even if the field were kept strong, but with the dropping of the field excitation the alternator became practically useless as a generator. If it were not for those outside sources of power the system voltage would simply go down, the load would be dropped off, and no damage would be done. But as soon as the rotaries stopped receiving current from the alternating-current side they began to receive it from the storage batteries and generators on the direct-current side. The rotaries then fed three-phase current back over the alternating-current line to the alternator. Some of the rotaries have reverse-current tripping apparatus on them, and these operated and cut those rotaries out of circuit. The few that were left were called upon to furnish current to the alternator—a unit eight times as large as either of them—and which acted as a huge motor.

Now, the current which this motor would take would be large in any case, but another factor enters into the calculation which makes it still larger, and this factor is induction. It is like pumping water through a very long pipe with a force pump. The pump is given a succession of strokes and the water moves, but on account of the inertia of the water the movement due to each stroke lags in time behind the stroke. The inertia corresponds to the induction. In the case we are considering the armature of the alternator furnished what is called an "inductive" load for the rotaries, and the current in the line lagged cosiderably behind the E M.F. The condition of each phase is shown in Fig. 2. Now, the energy in a line is a direct factor of the current multiplied by the voltage. At an instant (*x*), for example, while the product of the current and voltage is small, the current would be large. And this was exactly the case. There was an enormous current being sent out by the rotaries, but the biggest part of it was lagging way

Digitized by Google

behind the E.M.F., and this is the current that caused the trouble. This current reacted directly against the field of the rotaries and weakened them. These rotaries, remember, were at this time being fed from the direct-current side, and, therefore, acted as shunt motors. The effect of weakening the field of a shunt motor is to make it speed up. This is what the rotaries did. They began to speed up, carrying the turbine with them. The faster they went the larger lagging current was produced, and the weaker the fields became; so there was a continual acceleration until the enormous speed broke the circuit in the turbine-alternator. Since the turbines run normally at nearly three times as many revolutions as the rotaries, it will be seen that the speed of the former must increase rapidly with the increase of the rotary speed. As soon as the turbine began to speed up, the man in charge of it closed the emergency valve, thus shutting the steam off from it entirely. This is mentioned, not because it made any real difference, but merely to show that the steam did not have anything to do with the disastrous increase in speed.

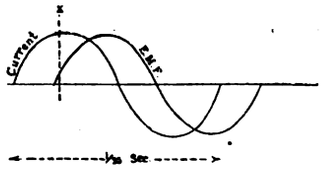

FIG. 2.

Now let us see what could have been done to prevent this: In the first place, if when No. 2 alternator short-circuited the operator had opened all the field switches on the machine, as well as opened those on the armature circuit, the ground on the exciter circuit would have been removed, the voltage on the field of the No. 3 alternator would have been high, and the alternator would have taken care of the load, perhaps under slightly reduced speed, until it could have been relieved. This opening of the field should always be done in the case of a short-circuited alternator armature; otherwise the generator will keep feeding the short-circuit, continually causing more damage. Again, if after the system had begun to speed up, the operator had opened the switches on No. 3 alternator, it would stop of its own accord, and the rotaries would gradually come down to normal speed, even if they were not cut out. Also if the sub-station operators had opened up their rotary circuits, either on the direct-current or the alternating-current side, the system would gradually come to rest. In defence of the operators it should be stated that the whole thing happened within the space of a few seconds.

This accident recalls one somewhat similar that happened on the New York Edison system some years ago. At that time one of the stations was feeding through inverted rotaries—that is, rotaries receiving current from the direct-current side—other stations of the same company. Through some accident a short-circuit was made on the high-tension line. All the rotaries immediately began feeding the short-circuit and receiving current from the direct-current sides. A large lagging current was produced, the fields of the rotaries weakened, and a general run away resulted, damaging some of the rotaries very badly.

WHISTLING GEORGE—WITH A MORAL.

George Barnes was a machinist by trade, and a whistler by profession. The statement is probably given in an inverse order; his profession was certainly the most prominent of the two qualifications; for whatever rank he might claim as a machinist, no one ever questioned his abilities as a whistler.

Whistling is very well at a proper time and place, and with a farther qualification as to quantity. It does much to relieve the tedium of shop manipulation, and is a common pastime with machinists; but the hero of this story was possessed of a mania for this shrill music, and hour after hour, if not day after day, he plied his notes, with pleasure and comfort to himself no doubt, but often to the great annoyance of those around him.

George, because of a want of musical taste on the part of his employers, had whistled himself out of a situation; and as his pecuniary affairs rendered it imperative that his machine fitting should go on with the whistling, he applied promptly for a new job at a large works near to where he had been previously employed.

The foreman being in need of hands, and favourably impressed with George, at once gave him a job to commence on the following morning. He was there promptly at the time with his tools and overalls, ready to begin. The foreman not having arrived, George sauntered around the shop examining the tools, and began in an unconscious way to whistle; but finding that it attracted the attention of the other workmen, who had never heard such an adept, he checked himself, feeling he was taking an unwarranted privilege in a strange shop. The foreman arriving, George was given his job for the day. The works, among other tools, employed several large punching machines; one of the dies having failed, George was given the bed-piece to prepare. The die was a solid block, about 12in. square, requiring a cylindrical hole 4in. in diameter to be made through the centre. It was forged from a tough, fibrous iron, about 4in. deep, with a steel facing ½in. thick on the face side.

George first drilled a starting hole through the piece, and then proceeded to "chuck" it on an old but powerful lathe used for drilling purposes. While mounting the work his attention was so much taken up in the search for bolts and blocks that the whistling was for the time neglected; besides, there had continually to be questions asked as to where tools were kept, and other things, and while George could do almost anything else and whistle at the same time, talking, of course, stopped his music.

When he finally had all arranged, his work chucked, a large flat drill prepared, and the belts adjusted, he began drilling, and there was nothing to prevent the music from commencing at the same time. Now, if there is anything more than another that provokes whistling in a machine shop, it is drilling, especially a large, deep hole, and the man who does not whistle when engaged at such work can be set down as "without music in his soul." There is a kind of stupor of the mind induced by its being for the time released from care of the work, and a person will whistle almost unconsciously, as a kind of relief to the monotony.

George had many a time been in circumstances that favoured the exercises of his piping proclivities, but never in his whole experience could he remember so propitious an occasion as the present one. Not that he thought of it in this light; he had no time to do so. The assumption is based upon the strength and continuity of his performance on the occasion. He whistled loud and long, soft and shrill, operas, hornpipes, marches, a very medley of tunes, apparently endeavouring to test his whole stock under such favourable circumstances.

A stolid German, who was working at a bench near by, would every now and then turn his head and stop his work in wonder, evidently enjoying the music, but astounded at the proficiency of the performer. The German had been but a short time in the country, and set this down as one of the prodigies among the many he had met with in the new land. An old shaft overhead that was out of repair by the screeching of a loose coupling marked time to the music, and blended like an accompaniment with the livelier tunes.

For an hour there was no cessation. The German began to think that whistling was the nominal condition of his new fellow-workman, and instead of looking around while the music was going on, he now found himself startled by its changes only. He even began to estimate as to whether the enjoyment derived from the music might not be in some degree measured by the amount that he might have to enjoy or endure.

In the second hour, and in the middle of a lively refrain, there was all at once, at George's lathe, a terrible crash, that called all hands to the place to see what had happened. Lying beneath the lathe was its face-plate with the die firmly bolted to it. The matter had a mysterious air, until someone noticed the lathe spindle, when the whole riddle was solved. George, engrossed with his whistling, had,

Digitized by Google

by starting on the steel side of the die, miscalculated or forgotten the time, and had drilled through the piece, the face-plate of the lathe, and bored off the end of the spindle.

We need hardly say that the whistling stopped; George stopped also, learning at the same time the truth of the old maxim, that, in the circumstances just described, "enough is plenty of anything," applied not only to the whistling, but to the drilling as well.

LONGTON ELECTRICITY ACCOUNTS.

The following are abstracts of the 1903-4 revenue account and of the balance-sheet of the electrical section of the Longton Corporation gas and electricity department. The capital expenditure for electrical purposes at end of financial year was £21,309.

REVENUE ACCOUNT.

Dr. Expenditure.	£	s.	d.
Generation of electricity	351	6	10
Distribution of electricity	20	4	0
Rates and taxes	80	8	4
Management	2	11	3
Special charges	73	17	5
Balance carried to net revenue account	714	12	9

STATEMENT OF ELECTRICITY GENERATED, SOLD, ETC.

Quantity generated in Board of Trade units		2,669,450
Quantity sold { Public lamps	326,731	2,223,923
Quantity sold { Private consumers	1,897,192	
Quantity used on works		407,450
Quantity accounted for		2,631,373
Quantity not accounted for		38,077
Total maximum supply demanded (kilowatts)		1,596

Number of public lamps: 167 arcs, 10 arcs (small), 75 incandescents.

TRADE NOTICES AND NOVELTIES.

Main Switches, Cut-Outs, etc.

The General Electric Company, Limited, Queen Victoria-street, E.C., have forwarded us a copy of their new list (X 1,060), in which it is stated that various improvements have been made from time to time, chiefly to keep pace with the increasing demand for high-voltage fittings, necessitating redesigning of apparatus to comply with the Board of Trade requirements. Several illustrations are shown of "Peel" and "Adelphi" main switches intended for switchboard work generally. These are substantially made, and possess many good features, chief of which is the long break. This break is very rapid in its action, and is properly arranged to allow of both contacts being broken simultaneously. The "Peel" switches are listed from 30 up to 1,000 amperes, either single, double, or triple pole, and are supplied with or without cut-out terminals. The change-over type range from 30 to 800 amperes, and are not provided with fuse terminals. Both types are constructed with strong dividing pieces of insulating material between the poles and the whole thoroughly finished. Carbon breaks are fitted to any switch where desired. A new type of "Adelphi" switch has been specially designed to meet the requirements of motor work. Two types of multiple switches are shown—viz., radial and rectangular—for regulating accumulator circuits and main resistances. The former is provided with a handwheel. The rectangular type is constructed with travelling contact brushes, which allow of uniform and smooth regulation from one contact to another. Shunt resistance regulating switches are also shown, and several types of house service fuses and main cut-outs. Amongst these will be found the "Concentric" (see

Digitized by Google

Fig. 1) for use on circuits where this system is in vogue. The "Pedestal" type cut-out is an excellent design, ensuring perfect and easy access for replacement of fuses, and has a good clearance of 1in. between the conducting parts and the frames, which is of cast iron with hinged cover. The terminals are mounted on porcelain, and can be supplied to take "Mordey" fuses. Two examples of main switchboard fuses are illustrated—viz., the "Bobbin" and "Arch" type. These are very substantially made, and consist of the well-known hollow china tube, with a lining of a patent fireproof composition. The fuse

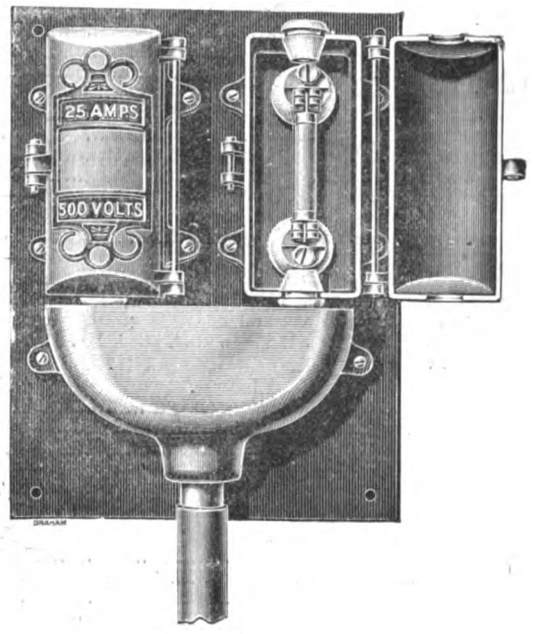

Fig. 1.—"Concentric" Main Cut-Out, for circuits up to 500 volts.

wires are clamped to solid gunmetal collars firmly fixed to the ends of the tube. Either type can be arranged to take a "Mordey" fuse in parallel. They are intended for circuits up to 500 volts, and are made to carry from 50 to 400 amperes. Illustrations are also given of the "Partridge" high-tension fuse (10,000 volts), and several voltmeter switches and ammeter plugs.

Catalogues.

The Electric Construction Company, Limited, Dashwood House, Broad-street, E.C., have issued a coloured illustrated poster showing of their engineering works at Wolverhampton, and of the standard types of generators, transformers, colliery haulage gear, mining locomotives, etc.

Excelsior System of Electrical Conduit.—The New Brotherton Tube Company, Limited, Excelsior Works, Commercial-road, Wolverhampton, have just issued their illustrated price list No. 5, in which they give details of conduits, switch-boxes, and fittings, etc.

Cryselco, Limited, Government contractors, Kempston Works, Bedford.—Cryselco lamps have been manufactured at the Kempston Works since 1885, since when a number of valuable improvements have been made, and the makers claim as a unique feature for this lamp that when run at the normal voltage, though of high initial efficiency, the consumption of current does not increase, and the light given does not materially decrease, during the first 1 000 hours' running.

Bailey's "Koester" Compressor and Vacuum Pumps. W. H. Bailey and Co., Limited, Albion Works, Salford, Manchester. Messrs. Bailey hold the license for the sole right of manufacturing in the United Kingdom compressors and vacuum pumps under the Köster patents. The mechanical and volumetric efficiency of these pumps is very high, and we propose to shortly deal further with the same as well as with the condensers. The latter are made on the single and multiple stage compound intercooling systems, the vacuum pumps being made on the single and double stage systems. All machines are arranged either for belt, steam, or direct electrical driving. The catalogue gives particulars and illustrates standard designs, and we are informed that although modifications and combinations of these machines can be made to suit customers' special requirements, the makers desire to keep to these standards in all cases wherever possible.

Flexible Cords.—The London Electric Wire Company, Limited, Anchor Works, Playhouse-yard, Golden-lane, London, E.C.

Photographers' Arc Lamps.—The Boardman Electrical Patents Company, Limited, 10, Southwark Bridge-road, London, S.E.

Lahmeyer New Motors.—Lahmeyer Electrical Company, Limited, 109, New Oxford-street (two new lists, describing continuous-current motors and the Schüler patent single-phase alternating-current motors.)

LEGAL INTELLIGENCE.

A SAFETY DEVICE.

At Manchester County Court last week his Honour Judge Parry tried an action arising out of a experiment made at Oldham with a patented invention for deadening the trolley wire of tramways in the event of accidents to the overhead equipment. The owner of the patent is Mr. J. A. Loughlin.

Two years ago, it was stated, he obtained permission from the Oldham Corporation to experiment with his invention on a section of their tramways. He employed Mr. Albert Maund, electrical engineer of Southport, to fix the apparatus on half a mile of trolley wire. When this had been completed, the device was tested and did not achieve the object for which it was erected. It was at once seen that the failure was due to the fact that the guard wires had not been isolated from the iron standards supporting them. The defect was remeded by another contractor, and then the device was found to work perfectly and to the complete satisfaction of members of the Corporation who were present at the test. The action was brought by Mr. Maund to recover from Mr. Loughlin the sum of £41. 11s., the amount expended on labour and material in carrying out the work. The defence was that the plaintiff had done the work negligently, with the result that the equipment had to be re-erected, and the cost of this re-erection was counter-claimed. The principal point made by the defence was that it ought to have been obvious to the plaintiff as an electrical engineer, even if he had received no express instructions on the point, that the insulators between the guard wires and the standards were essential to the successful working of the system. The plaintiff said he worked according to instructions which he received from day to day during the progress of the work.

The **Judge** said that as the plaintiff had no written specification to guide him, and as the work was of an experimental character, he thought it was absurd to charge him with serious negligence because he had not foreseen the necessity for insulators. He, therefore, gave judgment for the plaintiff on the claim and counter-claim.

PERSONAL.

The Burton-on-Trent Town Council have appointed Mr. T. Hall assistant electrical engineer at a salary of £150 per annum.

The Falkirk Town Council have appointed Mr. Theodore McDougald, of the Corporation electricity department, Dundee, as first assistant electrical engineer for the burgh at a commencing salary of £100 per annum.

The Paisley Town Council have increased the salary of Mr. Parkinson, the electrical engineer, by £100, making the salary £400, with free house, etc.

The Radcliffe District Council have appointed Mr. Geo. Nuttall as charge engineer, at 30s. per week.

Mr. E. J. Williams, chief assistant engineer, Hawick, N.B., has been appointed resident engineer at Inverness.

APPOINTMENTS VACANT.

Junior Assistants, Dundee Town Council, Sept. 28.

Draughtsman, Manchester district. See advertisement in last issue.

Estimating Assistant, North Country Cable Works. See advertisement.

Clerk, Heston and Isleworth Urban District Council, £100 per annum, Sept. 24.

Shift Engineer, Blackburn electricity department, £2 per week. See advertisement.

Wiring Inspector, Durban, Natal, £300 per annum. See advertisement in last issue.

Resident Electrical Engineer, Dartford, £250 per annum. See advertisement in last issue.

Chief Engineer and Manager, Southwark, £300 per annum, Oct. 5. See advertisement.

Electrical Engineer to take charge of driving and lighting plant of printing works. See advertisement in last issue.

Chief Assistant Engineer, Heston and Isleworth Urban District Council, £130 per annum, Sept. 24. See advertisement.

Electrical Assistant, Canterbury. Wages, 25s. per week. Applications to Engineer, Electricity Works, by 16th inst.

Electrical Engineer, with central-station experience, to manage and take charge of small lighting station in West Australia. Capital required, about £5,000. See advertisement in last issue.

Lecturer and Demonstrator, the School of Engineering, Electricity, and Technical Science, Canterbury College, University of New Zealand, £300 per annum. See advertisement in last issue.

Various.—Meter Fixer and Motor Inspector, £3 per week; two Switchboard Attendants, £1. 10s. per week; Fitter and Engine Driver, £2 per week; Assistant Engine Driver, £1. 10s. per week; two Stokers, 7d. per hour; Arc Lamp Attendant, £1. 10s. per week; Assistant to above, 15s. per week. Heston and Isleworth Urban District Council, Sept. 24. See advertisement.

COMPANIES' MEETINGS AND REPORTS

FERRANTI RECONSTRUCTION.

The liquidator, Mr. J. M. Henderson, has convened, by order of the Court, meetings of the creditors, preference shareholders, and debenture holders, to be held on the 29th inst., for the purpose of considering a scheme for the reconstruction of the Company. This scheme provides for the incorporation of a new concern, to acquire the assets of the old undertaking with a capital of £130,000, of which £60,000 is to be in 6 per cent. cumulative preference, £60,000 in 7 per cent. ordinary, and £10,000 in deferred shares. There are also to be created first debenture stock to the amount of £100,000 and a second debenture of £30 000, both bearing interest at 5 per cent. The holders of the first debenture stock and of the second debenture in the old company will receive in exchange for their present security first debenture stock and the second debenture in the new company, which will make itself responsible for all arrears of interest. The unsecured creditors of the old company will receive preference shares in the new company of the nominal value of their debentures, and the preference shareholders of the old company will receive ordinary shares in the new company of half the nominal value of their present holdings. The deferred shares are to be allotted to Mr. Sebastian Ziani de Ferranti, in consideration of which he will enter into an agreement to serve the new company for a term of years at £500 per annum, and to give the company the benefit of all his inventions in switch and meter work.

ELECTRIFIED TIMBER SEASONING AND PRESERVATION.

Accounts have been issued under the winding-up order showing liabilities £8,996, of which £3,896 is expected to rank, against assets valued at £10,402. The account with the contributories shows a deficiency of £105,780. The official receiver (Mr. H. Brougham), reports that the Company, which was promoted by the Founders' Syndicate, Limited, was formed in April, 1899, with a nominal capital of £150,000, to acquire the British patent rights in the Nodon-Bretonneau process of seasoning and preserving timber by electrical agency. The purchase price was £100,000, and was satisfied by the issue of £88,693 fully-paid shares and the payment of £11,307 cash. Some 28,000 shares were subscribed for, but upwards of 9,000 of these have been forfeited for non-payment of calls. The Company acquired a lease of land at Charlton, and erected buildings thereon costing between £5,000 and £6,000, with a jetty, which cost £700. To provide working capital for current expenses cash advances were made from time to time by the directors and their friends, which at the date of the winding-up order amounted to £4,948, and in respect of which debentures were issued charging all the assets of the Company. No receiver has been appointed, the debentureholders being treated as secured creditors in the liquidation. The failure of the Company is attributed to the want of working capital. The patents of the Company are valued by the directors at £10,000, but the official receiver observes that it is doubtful whether this amount will be realised.

BUENOS AYRES ELECTRIC TRAMWAYS.

The report of the Buenos Ayres Electric Tramways Company (1901), Limited, for 1903 shows that the gross receipts for the year from the sections opened for traffic amounted to £18,282, and the working expenses, inclusive of London administrative charges, to £15,913, leaving a net profit of £2 506. Of this £1,410 has been set aside as a sinking fund for the redemption of debentures, and the remaining £1,094 has been applied towards payment of the debenture interest accrued to Dec. 31, 1903. The balance of the amount required for the debenture interest to date has been provided by the vendor syndicate under the terms of the purchase agreement, dated Jan. 5, 1903. At the commencement of the year the line was working up to Maldonado (5·6 miles), and a further section from Gazcon to Triunvirato (1·5 miles) was opened in June last. On Oct. 22, 1903, the Chacarica section (three miles) was also opened, giving an immediate and encouraging increase in receipts. The construction of the remaining sections—namely, the Belgrano and Flores sections—was proceeded with, but as these were not completed during the year, no benefit accrued to the Company therefrom. The business of the Company was greatly hampered by the construction and heavy repairing work which was proceeded with throughout the whole year, not only on the new lines, but also on the old lines taken over, often necessitating the running of the tramway on a single track, and the results of the year cannot therefore be considered as giving any indication of the company's real earning capacity. The Belgrano section and the Flores branch have lately been opened. A concession has been applied for and granted by the municipality for an extension of the Belgrano section through the streets near the station of the Central Argentine Railway. The construction of this is being rapidly proceeded with, so that it may be open for traffic early in the ensuing summer season. A concession has been obtained for an extension of the Flores route. Since Dec. 31 last the traffic receipts have shown fair increases.

The meeting of the Company was held on Tuesday, when the report was adopted.

Mr. Charles Lock has been elected a director in lieu of Colonel Oldham, resigned.

DICK, KERR, AND CO.

The report for the year ended June 30 last, to be submitted to the meeting on the 27th inst., states that the profits amount to £84,170. Out of this had to be paid debenture and loan interest and trustees' fees, and there has been reserved the sum required to provide for the premium payable on the redemption of the present debenture stock. These items absorb £14,441, leaving £69,729, to which must be added the profits brought forward, £35,544, making a total of £105,274 available for appropriation. After paying the dividend on the preference share capital, it is proposed to carry one-fifth (£10,285) of the remaining profits to reserve as required by the trust deed securing the debentures, and also a further sum of £10,765 to bring it up to the limit prescribed by the deed; to pay a dividend of 10 per cent. on the ordinary shares, and to carry forward the balance of £39 922. During the past year the Company has completed, amongst other important contracts, the electrification of the Lancashire and Yorkshire Railway between Liverpool and Southport, and the Hong Kong and Mandalay electric tramway systems, and are at present busily engaged in Tokyo, Singapore, Bangkok, and other places both at home and abroad. The directors call the attention of the shareholders to the fact that the reserve to be set aside under Clause 31 of the trust deed securing the debenture stock has now reached the limit of £150,000 prescribed by that deed. Mr. Claud T. Cayley having retired from the chairmanship of the Company, Mr. John Kerr, M.P., has been elected in his place, and Mr. Cayley has accepted the position of deputy-chairman. The directors regret that in consequence of ill-health Mr. G. W. Carr has resigned his position as secretary of the Company, and they have appointed Mr. Frank Mott in his place.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Buenos Ayres.—The Municipality of Chivilcoy require tenders for installation of electric lighting.

Tynemouth.—The Corporation invite tenders for a 600-kw. steam dynamo by Sept. 30. See advertisement.

Salford.—The Electricity Committee invite tenders for paper-insulated cables. Tenders to the Town Clerk by Oct. 6.

Crejeur (Roumania).—The Municipality require tenders for construction and working of tramways for 50 years by Nov. 7.

Pretoria.—The Commanding Royal Engineer at Army Head quarters, Pretoria, is calling for tenders for the electric lighting of cantonments.

Mexico.—The Federal District Railway Company of Mexico require tenders for the electrification of six tramway lines in the town. Applications are to be made direct.

Espinar (Spain).—The Municipality require tenders for construction and working of an electric tramway for 20 years. Particulars from the Alcalde. Tenders by Oct. 12.

Pangbourne.—Tenders are required for lighting the village during the coming winter, for the Pangbourne Parish Council. Particulars may be obtained of Mr. C. West, jun., clerk.

The Hague (Holland).—The Council of the Hague require tenders for the supply of from 8,000 to 9,000 tons of steel rails, including appurtenances, for electric tramways. Tenders by Sept.

Arenas de S. Pedro (Spain).—The municipality require tenders for electric lighting for eight years. One hundred 10-c.p. lamps are required for public lighting. Tenders by 25th inst. to above.

Edmonton.—The Urban District Council desire to enter into an arrangement with a company for the exercise of their powers under their provisional order. Tenders by Sept. 27. See advertisement.

Ilford.—The Urban District Council invite tenders for the supply and erection of balancer and switchboard panel, and reversible traction booster and switchboard panel. Tenders by Oct. 4. See advertisement.

Mortlake.—The Urban District Council invite tenders for wiring their isolation hospital, South Worple-way, Mortlake, for the electric lighting. Tenders to Mr. John Eustace Anderson, clerk, High-street, Mortlake, by 12 noon on Sept. 27.

Aberdeen.—The Tramways Committee invite tenders for the supply and delivery of 20 top-deck car-covers. Drawings and specifications may be had from Mr. J. Alex. Bell, city electrical engineer, Aberdeen. Tenders by Sept. 27. See advertisement.

La Paz (Bolivia).—The Municipality require tenders for the electric lighting of the town for 12 years. There is an old central station and water power of 150 h.p. to 200 h.p., which is sufficient for the number of lamps required. Tenders by Jan. 15, 1905.

Tynemouth.—The Corporation invite tenders for the supply and erection at their electricity works, Tanners-bank, North Shields, of one 600-kw. steam dynamo. Tenders to Mr. Horatio A. Adamson, town clerk, Town Clerk's Offices, Tynemouth, by Sept. 30.

Hull.—The Corporation invite tenders for wiring and fitting Beverley-road baths. Particulars, etc., of Mr. A. E. White, city engineer, Town Hall, Hull. Tenders to the Chairman of the Baths Committee, Town Clerk's Office, before 10 a.m. on Sept. 30.

Canterbury.—The Drainage Committee invite tenders for electric light fittings in the engine-house at the sewage farm. Particulars may be obtained of Mr. Arthur C. Turley, A.M.I.C.E., city surveyor, Guildhall-street, Canterbury. Tenders to the Town Clerk by 10 a.m. on Oct. 3.

Weymouth.—The Town Council invite tenders for the wiring of 12, Gloucester-row, in accordance with specification and conditions which may be seen at the offices of the Borough Electrical Engineer, Sunnybank, Westham. Tenders to the Guildhall, Melcombe Regis, by 3 p.m. on Oct. 3.

London, S.W.—The London County Council invite tenders for the manufacture, delivery, and erection of three electric car traversers at certain of the Council's tramway depôts in the South of London.

Digitized by Google

Specification, etc., may be obtained at the County Hall, Spring-gardens, S.W. Tenders by 10 a.m. on Oct. 4.

Rochdale.—The Tramways Committee require tenders for the wiring of car depôt. Applications, with £1. 1s. deposit, to Mr. C. C. Atchison, borough and tramways electrical engineer, Rochdale. Extra copies 5s. each. Tenders, endorsed "Car Depôt Wiring," to be addressed to the Town Clerk, Town Hall, Rochdale.

Philippopolis (Roumelia).—The Municipality requires tenders for a concession to construct and work electric lighting and tramways for 50 years. A guarantee of £6,000 is required. Tenders by Oct. 15. On the next day a second adjudication will take place in case there is an offer of £5 per cent. less per kilowatt-hour than the minimum.

Tschatschak (Servia).—The Electricity Company Owtschar und Kablar in this town require two turbines of 750 h.p. each, two generators for three-phase currents, and other plant for the erection of a hydro-electric central station, and equipment of lines of distribution within 40 miles, by Oct. 2. Specifications, etc., may be obtained from the Manager of the Company.

Bangour (Scotland).—The Edinburgh District Lunacy Board invite tenders for (1) electric wiring and cables, (2) telephone installations, (3) electric bells, required in connection with certain buildings erected and to be erected at Bangour. Tenders to be lodged with Mr. And. Ferrier, clerk, Edinburgh District Lunacy Board, Castle-terrace, Edinburgh, by 28th inst.

Greenwich.—The London County Council invite tenders for the manufacture, delivery, and erection at the tramways electricity generating station of Greenwich of the following plant: two 24in. centrifugal pumps and motors, one 3in. centrifugal pump and motor, two 8in. by 8in. three-throw air-pumps and motors, one 3in. artesian well pump, fixed and rotary strainers, etc. Specifications, etc., may be obtained at the County Hall, Spring-gardens, S.W. Tenders by 10 a.m. on Oct. 4.

London, N.—The Edmonton Urban District Council desire to enter into an arrangement with a company for the exercise of their powers under their provisional order. They are prepared to consider offers based upon certain alternative arrangements, particulars of which are set out in the form of tender. Particulars and form of tender may be obtained at the office of Mr. William Francis Payne, clerk, Town Hall, Edmonton. Tenders must be addressed to the Clerk, and delivered by 12 noon on Sept. 27.

La Rochelle (France).—The Chamber of Commerce will shortly issue tenders for a crane with a lifting power for 30 tons. The beam, or the part which projects over the water or vessel alongside, should be long enough to unload from a point about 26ft. 6in. from the edge of the quay. The height of the distal end above the quay should be 15m. (49·21ft.); the vertical distance between the edge of the quay and that part of the crane directly over it, 8m. (26·4ft.). A locomobile is preferred, but should the conditions be unfavourable for installing such a machine, then a fixed crane would be adopted.

Shanghai.—The Board of Trade have received through the Foreign Office copy of a telegram from the British commercial agent in Shanghai to the effect that tenders are invited by the municipality of that city for the construction and working of 24 miles of electric tramways on the trolley system, double or single. Conditions of contract, together with plans, etc., may be seen on application to Messrs. Pook and Co., agents for the municipality of Shanghai, 63, Leadenhall-street, E.C., and such modifications of the conditions as may be necessary may be made by tenderers. Tenders must be sent in by March 31, 1905.

London, S.W.—The London County Council require tenders for the manufacture, delivery, and erection at the Council's tramways electricity generating station at Greenwich of two 24in. centrifugal pumps and motors, one 3in. centrifugal pump and motor, two 8in. by 8in. three-throw air-pumps and motors, one 3in. artesian well pump, fixed and rotary strainers, etc. Persons desiring to submit tenders may inspect the drawings and obtain the specifications, bills of quantities, form of tender, and other particulars at the County Hall, Spring-gardens, S.W., upon payment to the Cashier to the Council of £2 deposit. Tenders to be addressed to the Clerk of the London County Council, Spring-gardens, S.W., and marked "Tender for Pumping Plant." No tender will be received after 10 a.m. on Oct. 4.

RESULTS OF TENDERS.

Swansea.—The Town Council have accepted the tender of Laidlaw, Laidler, and Co., Stockport, at £250, for two negative tramway boosters.

Saffron Walden.—The Town Council have accepted the tender of Messrs. Godfrey for electric bells at £37, and £3 a year for maintenance.

Oban.—The Town Council have accepted the tender of the St. Helens Cable Company, at £37. 10s., for the supply of 240 yards of three-core unarmoured cable.

Ilford.—The District Council have accepted the tender of F. and A. Willmott, Ilford-hill, Ilford, Essex, at £1,243, for extensions to buildings at the electric lighting station.

Worksop.—The Electric Lighting Committee have recommended the acceptance of the tender of W. T. Glover and Co., Limited, at £786. 9s. 6d., for the supply of armoured cable.

Carnarvon.—The Hart Accumulator Company have secured the contract for the supply of storage battery, consisting of 256 of their standard lighting type cells, at the electricity works.

Hammersmith.—The Borough Council have accepted the tender of the Beldam Foundry Company, at £90, for cast-iron pipes, and that of Westwood and Wrights, at 39s. 6d. per yard, for wrought-iron pipes.

Philpstoun Oil Works.—The British Electric Plant Company, Alloa, N.B., have been awarded the contract for three electric power generators, of 250 h.p. each, for James Ross and Co., Philpstoun Oil Works.

London, S.W.—The Chelsea Guardians have received the following tenders for wiring the wards of the infirmary for electric light:

Coleby and Co., 7, Thayer-street, W.	£585	10	0
W. Smith, College-street	642	0	0
Bolton, Fane, and Co., Goswell-road	652	0	0
P. McCarthy, Fulham-road	475	0	0
W. Seymour, Sloane-square	547	0	0
Wells, Raynor, and Co., Limited, Paddington-street, W.	399	0	0
Buckley and Beach, Cale-street	545	0	0
G. E. Taylor and Co., 8, Bush-lane	480	0	0
M. Wiedhofft, Islington	366	0	0
J. Boulding and Sons, Upper Marylebone-street	403	10	0
E. P. Allam and Co., Hatton-garden	430	0	0
E. Probert and Co., Bond-street	511	0	0
Donnison, Sillem, and Co., Great Portland-street	618	0	0
T. Potter and Sons, South Molton-street	525	0	0
T. Clarke and Co., Sloane-street	481	4	6
C. Mickleborough, 420, Harrow-road (accepted)	366	17	6
District Electric Company, Wolverhampton	380	0	0
W. Wing, Borough	399	4	0
Lee and Warren, Kettering	375	0	0
Fryer and Co., Sloane-square	508	0	0
P. Turner, Markham-square	995	0	0
Smitham and Page, Queen Victoria-street	552	3	0
Engineering Company, York-place, Portman-square	537	9	0
Farringdon Electric Wiring Company, Farringdon-road	530	3	0

BUSINESS NOTES.

TRACTION.

Exeter.—The construction of the first section has been somewhat retarded by the weather, but excellent progress is being made.

Warwick.—The Corporation have approved the plans submitted by the company for the electrification of the tramway to Leamington.

Bury, Oldham, and Rochdale.—The directors of the company are to receive an honorarium of £2,000 for successfully negotiating the sale of the undertaking.

Liverpool-Southport.—The electric service on the Liverpool-to-Southport branch of the Yorkshire and Lancashire Railway has been considerably increased.

Paris Underground Railway.—The æsthetics may rejoice! A polished balustrade now surrounds the space in the Place de l'Opera leading to the station, in lieu of the high hoarding previously enclosing the site.

Paisley.—A trial trip was run on the Renfrew section last week, and proved satisfactory. It may be a week or two before the service will be opened to the public, as the overhead wires to the extremity of the route have not been completed.

Southampton.—The extensions contemplated by the Corporation, which were practically decided upon some time ago, were the subject of a formal resolution of approval at the last meeting of the Corporation, and application is to be made for a provisional order.

Tunstall.—The Urban District Council have given their sanction to the laying of a line by the British Electric Traction Company to connect the system with the Chatterfield-Whitfield Collieries for the purpose of conveying fuel to the company's generating stations.

Swansea.—The borough electrical engineer, Mr. Prusmann, reported at the meeting of the Town Council that the work in connection with the tramway contracts was progressing in an entirely satisfactory manner, both in relation to the rate of progress and the quality of the work.

Mansfield.—The Council have approved the plans for the light railway with the exception of minor points, and last week representatives of the Council and the promoters inspected the routes. The plans still await the approval of the Board of Trade, after which an early start is expected to be made.

Christchurch (N.Z.).—Sleeper and ballast construction has been adopted for the tramways in preference to concrete construction, which proved unsatisfactory in Auckland. The contractors are proceeding rapidly. The permanent-way materials are well in hand. It is hoped the first section will be opened for traffic early next April.

Hyde, Stalybridge, etc., Board.—As the result of the new railway bridge at Throstle Bank, Hyde, undertaken by the Joint Board, there will be a branch line for the benefit of residents in Dukinfield-road. The old bridge was too narrow to allow of the electric cars passing under it, and the Board decided upon a larger one at a cost of £5,000.

Belfast.—The Corporation have given a general approval to the joint specification prepared by the electrical engineer, the tramways manager and the city surveyor. A consulting expert is not deemed necessary by the Corporation, but the electrical engineer has been instructed to report to the committee if any special points calling for expert advice arise.

Manchester.—The Tramways Committee having inspected various top-cover designs, have decided to adopt a pattern with movable windows and ventilating louvre on the top. This is to be fitted to 100 of the cars, and the cost will be £124 a car. The work will be put in hand at once, so that as many as possible of the cars may be ready for use during the coming winter.

Bettws-y-coed Light Railway.—The order made by the Light Railway Commissioners sanctioning the construction of this railway, subject to one or two restrictions affecting the scenery, has been sub-

Digitized by Google

mitted to the Board of Trade for confirmation. A correspondent to the *Times*, after reciting the advantages of and objections to the scheme, suggests that the purpose would be better served by a motorcar service.

Anglo-Argentine Tramways Co.—The directors have declared an interim dividend on the ordinary shares at the rate of 6 per cent. per annum, leaving a balance of £34,614. This sum, together with the surplus carried over from last year's accounts (amounting to £4,120, after deducting the 2,000 guineas voted to the chairman at the last annual general meeting), will be dealt with in the final accounts at the end of the current year.

Halifax.—In reference to the line to be extended to Sowerby Bridge, it is understood between the Corporation and the Sowerby District Council that the latter will remit the rates on the portion of the tramway within their area, but as the Legislature does not recognise such an arrangement, the District Council have passed a resolution consenting to support the Bill to be promoted by the Corporation, in which they will seek the necessary sanction.

Cambridge.—The Corporation and the Cambridge Electric Tramways Syndicate, Limited, have arranged terms, described in another column, under which the latter are to electrify and extend the tramways. The total length of the scheme amounts to nine route miles, including extensions of the Station and East road to Market-road sections. Energy will be taken from the Cambridge Electric Supply Company. The syndicate will promote a Bill next session.

Baker-street and Waterloo Railway.—Mr. Chapman, chief engineer to Mr. Yerkes, stated to a *St. James's Gazette* representative that the syndicate have been compelled to give an order, valued at £100,000, for a hundred cars to the American Car Company, because they were unable to obtain a quotation in England or on the Continent. Further cars, to the value of £300,000, will, Mr. Chapman added, be required for the other tubes, and he states that these will be bought in this country if possible, otherwise the company must again go to America.

Stockport.—There has been a renewal of the negotiations between the Corporation and the company. At a meeting last week the former made an offer of £23,500, but the company held out for £24,000. Arbitration was suggested, to which the representatives of the company replied that they had no authority from the shareholders to consent. A special meeting of the Corporation is to be held, when the question of accepting the company's terms will be discussed. Just as we go to press we learn that the Corporation have decided to accede to the company's terms.

Aston.—A trial of the reconstructed tramlines between Aston Cross and the parish church took place last week, when one of the Birmingham Corporation cars were run over the route. The car ran to the satisfaction of all parties. Amongst those who were present to conduct the test were Alderman W. Evans (chairman of the Aston Pubic Works Committee), Mr. Robert Green (consulting tramways engineer to the Aston Corporation), Mr. Baker (representing the Birmingham Corporation), and Mr. Conaty (representing the City of Birmingham Tramways Company. The service was opened to the public this week.

Chester.—Mr. John Gardner, Corporation tramways manager, has issued the following report on the July and August working: The receipts for July show an increase of £64. 11s 11½d. as compared with the corresponding month of last year. The takings for August show a slight decrease of £5. 19s., which is accounted for by the fact that in August last year there were five Saturdays, whereas this year there were only four. The net increase for the two months is £58. 12s. 11½d. The increase is chiefly in 1d. and ½d. fares." The cars have now been running for two months, and Mr. Gardner recommends the application of a little varnish.

South Shields.—A special meeting of the Corporation was held on Monday in reference to the discovery of a private document relating to the tramway negotiations. This purported to be a communication from certain parties not disclosed to the British Electric Traction Company, stating that "they had been in constant communication with two members or friends of the company on the committee." It will be remembered that when the question of the tramways was before the Corporation recently, it was stated that the committee would be ready with their report in November. In view of the above development, however, it is reported that a special meeting is to be held on the 29th inst. for the purpose of considering a proposition in favour of municipalisation.

Cardiff.—At a meeting of the Finance Committee on Monday the estimates for the half-year ending March next showed that the anticipated surplus from the tramways for the year 1904-5 was £5,980. 18s. 10d. The Tramways Committee have not yet decided how to allocate this, and it was therefore agreed not to take the amount into account by reducing the rate to that extent. Incidentally Mr. Ellis, the manager, intimated that he proposed recommending the committee to set aside all the profits earned towards reducing the capital paid to the old tramways company for their undertaking, upon which a councillor said he should oppose such a course being adopted, adding that a rearrangement of fares was urgently needed. Mr. Ellis has this point under consideration.

London County Council.—The Stoke Newington Borough Council had on its agenda for last Tuesday's meeting a recommendation by the Tramways Committee that the Board of Trade be asked not to sanction the use of a centre slot 1in. in width in lieu of ⅜in. for the County Council's tramways. The committee pointed out in their report that certain sections of the Bournemouth tramways (to which the County Council had referred) are worked, not with a 1in. centre track slot, but with a 1in. side or rail slot, except at the termini, points, and crossings, where a ⅜in. slot is used, in regard to which no difficulty has been experienced. The committee consider that a 1in. slot might be attended with inconvenience and danger to other traffic. A service has been started between Southwark Bridge and Tooting, and another between Westminster Bridge and the Tower Bridge, the route taken being by way of the Obelisk, Elephant and Castle, New Kent-road, and Bermondsey New-road. A service between Westminster Bridge and Southwark Bridge is under consideration.

Liverpool.—At last week's meeting of the Corporation, a resolution was proposed that a universal 1d. fare should be adopted. The Tramways Committee had previously decided against the principle, and the proposal was withdrawn on the chairman of the committee giving a promise that the manager should report upon the advisability of giving those travelling before eight o'clock in the morning, the majority of whom were working-men, the privilege of riding the whole distance for 1d., and the option of purchasing a ticket to return in the evening at the same rate. On Wednesday the Corporation considered a scheme for providing routes within the city for joining up the existing system, and also sections of light railway to Woolton, Speke, Halewood, Ditton, Widnes, and Fazakerley. The length of proposed new tramways is nearly 12 miles, whilst that of the suggested light railways is rather longer. As noted last week, top covers have found favour with the Corporation, and some half-dozen cars are to be fitted up experimentally. At the conference between the Tramways, Estate, and Health Committees, it was agreed that the widening of Edge-lane to allow of a double track would entail too great an expenditure. The plough lifeguard demonstrated its value last week, when in three cases children escaped practically scathless.

Keighley.—At Tuesday's meeting of the Corporation it was stated that the tramways might be available in about a month. The proposed Stockbridge extension was again discussed, and a proposition that the scheme be adopted was carried. Single track will be used. The eight cars ordered by the Corporation have been delivered. The vehicles are of the latest design, and include all the improvements recommended by the Board of Trade and adopted by the leading makers. The bodies and trucks have been made by the Brush Electrical Engineering Company, of Loughborough, and the motors and controllers by the British Thomson-Houston Company, of Rugby. The motors, which are worked at a pressure of 500 volts, direct current, are capable of giving a maximum of 35 h.p. A trial trip was made the other day from the tramshed in South-street to the Ingrow terminus. A special switchboard has been erected at the power station for working the tramways, and one of the 200-h.p. engines and dynamos will be used for generating the power. The engines and dynamos which were laid down at the generating station four years ago will at present suffice for lighting, power, and tramway purposes, but as the demand for electricity for lighting and power purposes is rapidly increasing, it is quite possible that the plant will have to be extended next year. This the Corporation have foreseen, and borrowing powers have been obtained.

Bradford.—The report of the general manager (Mr. C. J. Spencer) on the year's working to March 31 has just been issued to the members of the Tramways Committee. We published particulars of the year's accounts some weeks back. The total income amounts to £197,437. 13s. 5d., or 10·421d. per car mile, an increase in the aggregate of £23 903. 7s. 11d., or ·044d. per car mile since March 31, 1903. As to whether these figures can be considered satisfactory or no, Mr. Spencer invites a comparison with the accounts of the various municipal tramway concerns of the size and importance of Bradford, bearing in mind the route miles laid in each case and the population served. Mr. Spencer directs attention to the following features: first, the receipts per 1,000 of population served are well above the average; and, secondly, the receipts per route mile of tramway in operation are several thousand pounds below systems of like size and importance. Mr. Spencer attributes the interest in working costs the hilly character of the new routes, their distance from the power station, the increased power consumption resulting from top-covered cars, which he states require 15 to 20 per cent. additional energy, and the overloading of the power cables, causing high transmission losses. The last-mentioned factor is being dealt with by the Electricity Committee. Careful management has resulted in an appreciable decrease in coal costs. The expenditure on rolling-stock repairs has been high, and in this respect the manager adverts to his contention, advanced in a former report, that, as a general rule, repairs will vary *pro rata* with the current consumption per car mile.

LIGHTING AND GENERAL.

Radcliffe.—The electricity works are to be formally on Wednesday, Oct. 5 next.

Harrogate.—A number of additional incandescent and Nernst lamps are about to be placed on the streets.

Armagh.—It has been decided to extend the lighting of the fish wharf by placing 10 arc lamps south of the ferry.

Whitby.—An enquiry has been held into an application for sanction to borrow £3,100 for further purposes for the electric light.

Sale of Plant.—The St. Pancras Borough Council invite offers for engines and dynamos. Particulars appear in another column.

Leigh.—The Town Council have adopted a report of the Electricity Committee recommending extensions estimated to cost £16,000.

Babcock and Wilcox.—The directors have declared interim dividends of 1s. 7½d. each on the ordinary and preference shares.

Luton.—The Council have sealed an agreement with the Midland Railway as to carrying the electric cable underneath their bridges.

Southampton.—Sanction has been received to the borrowing of £22,000 to meet prospective expenditure on electric lighting mains and services.

Irthlingborough.—Mr. Harvey, of Richmond, intends to apply for power to supply electricity to Rushden, Higham, and Irthlingborough.

Digitized by Google

Dalkeith.—The Town Council have signed an agreement with Messrs. Crompton and Co. in regard to the lighting of the streets by electricity.

Lynn.—Sanction has now been received to a further loan of £2,756 for electricity purposes, making a total of only £78 less than the Council at first applied for.

Removal.—Messrs. F A. Glover and Co., Limited, Garrick-street, W.C., will on Sept 24 move into larger premises at Vine-street, E.C. (off Rosebery-avenue).

Brighton Telephones.—The manager is ordering from the International Electric Company a new switchboard and batteries at the cost of their estimate of £55.

Portpatrick.—An electric lighting installation for the streets in and the roads around the town was officially opened last week by Lady Augusta Orr-Ewing of Dunspey.

Drighlington.—The Yorkshire Electric Power Company are about to lay cables, junction boxes, etc., on the Leeds and Whitehall road from Birkenshaw boundary to Farnley.

Direct Spanish Telegraph Co.—The directors have decided to pay an interim dividend at the rate of 4 per cent. on the ordinary shares for the half-year ended June 30, 1904.

Calcutta Electric Supply Co.—The directors have decided to declare an interim dividend on the paid-up share capital of the company at the rate of 6 per cent. per annum for the half-year ended June 30 last, payable on Nov. 15 next.

Agency.—The London Electric Wire Company, Limited, Anchor Works, Playhouse-yard, Golden-lane, London, E.C., have appointed Mr. David Alexander, A.M.I.E.E., 43, Mains-street, Waterloo-street, Glasgow, as their representative for Scotland.

Norwich.—The Executive Committee have accepted the offer of the Electricity Committee to light Prince of Wales's-road, from Thorpe Station to Bank Plain, with 12 arc lamps, at £16 per annum each for eight lamps lighted all night, and £12 per annum each for four lamps lighted up to midnight.

Hove Electric Lighting Co.—The directors have decided to declare an interim dividend on the paid-up share capital of the company at the rate of 3½ per cent. for the six months ended June 30 last. The dividend, which is the same as at this period last year, will, as usual, be paid on Oct. 15 next.

Abyssinian Telephones.—It is reported that nearly 800 miles of wire have been put up in Abyssinia, and 1,000 miles more are planned. There are many difficulties in the way, for while white ants completely detroy wooden poles in the ground, iron poles are stolen by the natives, who want them to make tools of.

London Gazette.—Edward Thomas Peirson, 17, Hertford-street, Coventry, has been released from trusteeship in the estate of William Henry Hooley and John William Talbot (carrying on business as Hooley, Talbot, and Co.), electrical engineers and contractors, residing and carrying on business at Regent-street, Rugby, Warwick.

Calcutta.—The Government of India have sanctioned the expenditure of Rs 50,000 on the purchase of electric transporters for use at Shalimar. The Municipality of Darjeeling have been granted a license, under the Indian Electricity Act of 1903, to supply electricity within certain specified areas in the town and neighbourhood of Darjeeling.

Stratton's Patent Four-Way Hydraulic Valve.—The sole licensees and makers of this gear, Messrs. David Bridge and Co., Castleton, Manchester, have just published an interesting pamphlet fully describing these valves, and we believe that a copy of the same will be sent to any of our readers who care to apply to Messrs. Bridge for it.

New Cable.—The French Government have decided to cross the Great Sahara from South Algeria to the West Coast by an electric cable, which is to be laid from In-Salah, *via* Tidekalt and Tageneut, to Timbuctoo. The distance is about 620 miles, and the estimated cost amounts to £60,000. The work is to be completed in about 12 months.

Harwich.—The proposed electric lighting of the borough is the subject of a report which will be discussed at the next Council meeting. It is suggested that the three-wire low-pressure system should be adopted, and that current be supplied at 6d. per unit. A refuse destructor is proposed at a cost of £3,000, while the total expenditure is put at £21,012.

New Barnet.—The District Council propose to enter into an agreement with the National Electric Construction Company for an electric lighting scheme estimated at £16,375, and having regard to the comparatively large sum proposed to be expended for the purpose, they have agreed that the ratepayers should be offered an opportunity of expressing their opinion on the proposed scheme.

Walsall.—The following figures are available for Aug. 31: Total number of consumers supplied, 360; total units generated at the station during the past month, 117,994; total output from the main generators, 114,391 units; total units from the transformers, 88,878 (estimated); total units registered, 88,699. The machinery was run for 708 hours, and the wages paid amounted to £124.

Sleaford.—The Electric Lighting Committee reported at the last Urban District Council meeting that they should not have to make any call upon the rates for the present half-year. They had decided to erect a new workshop, and were going to ask for tenders. Up to the end of the last half-year the receipts from private lighting had been £346, and the gross profit on the working of the scheme had been £205.

Swansea.—The electrical engineer's report for September stated that there were 553 consumers on the books. Mr. Prussman hoped to have a limited electric light supply for Morriston ready by the end of September. The work on the arc lighting of St. Helens road is now completed. There was an increase of 37,120, or 21 per cent., in the units sold during the quarter ending June last as compared with the corresponding period of last year.

Agency.—Messrs. Cecil Hodges and Co., Balfour House, Finsbury-pavement, E.C., have appointed Messrs. W. G. Morrison and Co., of 59, St. Vincent-street, Glasgow, as their sole agents for Scotland, Mr. James Gray, of Glasgow, having ceased to represent the firm for that district. A new catalogue fully illustrating and describing various types of instruments, switches, etc., has been prepared, and will be posted to any of our readers sending a trade card to Messrs. Hodges.

Stock Exchange.—The Stock Exchange Committee have appointed Wednesday, Sept. 28, a special settling day in London Electric Supply Corporation, Limited, further issue of 10,000 6 per cent. preference shares of £5 each, fully paid—Nos. 50,001 to 60,000—and United River Plate Telephone Company, Limited, further issue of 12,000 ordinary shares of £5 each, fully and partly paid—Nos. 58,001 to 70,000—and have ordered the first-mentioned securities to be quoted in the official list.

Stoke Newington.—On the agenda for this week's Council meeting we note: "To consider the following business (adjourned from July 19, 1904)—viz.: (*a*) report of the Electric Lighting Committee on an electric lighting scheme for this borough, and submitting an agreement with the North Metropolitan Electric Power Supply Company for adoption and sealing by the Council; (*b*) the appointment of a Standing Electric Lighting Company for the remainder of the current year, consisting of 11 members."

Hull Telephones.—The formal opening of the exchange in Trippet will take place soon. Up to the present 1,600 subscribers have been obtained out of the 2,000 which the Council guaranteed; 100 of these have already been connected, and the intercommunication is working with perfectly satisfactory results. The first cable was only laid in January, and to-day cables have been laid for 2,000 subscribers. Wires have also been laid to Kirkella, and another line goes from Springhead to Anlaby and Hessle, where an exchange will be open in the course of a week or two.

Saltney.—The Flintshire Council at their last meeting discussed the following communication from the Saltney Parish Council: "The Council have adopted the Lighting Act. The question of electricity seems to be the favoured system. Before asking for estimates I am instructed to ask your Council whether any objection would be taken to overhead wires in place of underground. Part of the area would be on your main road from Shotton Church to the Bridge Inn at Sandycroft, and from cross roads at Queen's Ferry to Hawarden Castle Hotel. The rest on District Council roads. The overhead system would be much the cheapest." It was decided to inform the Parish Council that the County Council approve and recommend the underground system.

Saffron Walden.—The Corporation have entered into an agreement with Messrs. Foote and Milne for installing electric lighting, and an enquiry has been held into an application for sanction to borrow £9,950 for the purpose. It is proposed to use the boilers connected with the electric lighting for working the pumping machinery. The cost of the day shift will fall upon the waterworks on account of the use of the boilers, and the electric lighting undertaking will provide the coal. During the past 10 years the amount of coal consumed per 1,000 gallons of water pumped was 12½lb. The water undertaking propose to pay the electric lighting undertaking at that rate for the coal on the average price for the year.

Birmingham.—The work of excavations and laying the foundations for the new generating station on the site of the old general hospital is proceeding apace. The building of the station will soon be begun. The estimated cost of equipping the station to the full ultimate capacity of 22,000 kw. is £380,000, while the estimated cost of the necessary building is £130,000. For the present, however, the Electric Supply Committee believe that the needs of the department will be met by the equipment of the station to a capacity of 8,500 kw., at a total cost of £260,620. The buildings, upon which a start will shortly be made, will include an engine-house 275ft. long by 100ft. wide and 65ft. high. The boiler-house will be of similar dimensions, and there will also be a small pumping station, workshop, and engineers' stores and offices. Five new sub-stations will ultimately be necessary, and the existing station at Parker-street will require alterations.

Mexborough.—A petition by private consumers is before a committee. It is really a protest against the Council supplying current to the Great Central Railway Company at 2d. per unit. The petitioners asked for a reduction from 5d. to 4d. per unit, and contended that if the Council could afford to put down larger engines, and otherwise incur extra expenses to meet the requirements of their large customer (the Great Central Railway Company), they could well afford to grant the request. It was further pointed out that many of the smaller consumers were induced to use the current on the statements made in handbills, issued by the Council, that at 5d. per unit it was equally cheap or cheaper than gas at 3s. 3d., which by practice they had found incorrect, experience having taught them that electric light worked out at about double the cost of gas. The balance-sheet of the electric undertaking showed in revenue account that the sale of electric current had increased from £565 in 1903 to £995. Public lighting in 1903 cost £645, while this year £903 had been paid. There was a loss of about £340, as against a deficit of £179 the previous year, notwithstanding that a sum of £550 received by the committee as damages from contractors for late arrival of machinery was included in the net revenue account, bringing a deficit of about £720 down to £170. No allowance had been made for renewals or depreciation, but during the year £569 had been repaid of borrowed capital, and £565 interest on mortgage debt, the most satisfactory aspect of the report.

Digitized by Google

Machine Drawing.—Messrs. P. S. King and Son, Orchard House, Westminster, have issued at 2s. 6d. a large collection of plates, which are fully described in the text, and which will be welcomed by many evening students who are unable to attend more than one evening class a week, and who will find the volume extremely useful for obtaining a practical knowledge of machine drawing. It will at the same time assist them in the study of elementary calculations connected with separate machines.

Walton.—The difficulty arising out of the injunction obtained by the Weybridge Urban District Council, restraining the Urban Electric Supply Company from supplying current from their works in that parish, has been removed. Edmundson's Electricity Corporation, Limited, propose to utilise the site of the old brewery for the substation in Walton, and to instal for temporary use a pair of portable boilers and an engine set, an apparatus to soften (if not altogether do away with) the noise from the exhaust of the engine, etc., so as to supply current during the coming winter.

Bristol.—An enquiry has been held into the application of the City Council for powers to borrow £126,500 for the purposes of the electric lighting. Mr. Faraday Proctor, chief electrical engineer, produced the plans, and explained the amount expended (£601,893) and the amount borrowed from 1902 up to date (£574,080). Part of the new loan was required for the extension of the mains. They had already put in hand some of the work which was necessary consequent on the fire at the Temple Back station at Christmas last. It was proposed to replace the destroyed switchboards by fireproof switchrooms. The plans had all been passed by Colonel Yabbicom's department.

Hammersmith.—The Electricity Committee's last report states that the premises of 40 additional consumers, representing a maximum of 1,083 8-c.p. lamps, have been connected to the mains; that 18 consumers have been disconnected; and that the present number of consumers taking current from the mains is 1,500. The builders of the London Bishopric Estate, Uxbridge-road, propose wiring the whole of the houses to be erected upon this estate, provided mains are laid and a supply of electricity given at a satisfactory rate. The estimated total cost of laying the mains (including high-tension feeder from Boscombe-road) is £983. 5s. 6d., but as it will be some years before all the houses are erected, a portion of the mains to the value of £100 will be laid at the present time.

Robertson Electric Lamps' Fire Brigade.—The competition for the championship of the private fire brigades of the United Kingdom was held at the Crystal Palace on Saturday last. The teams consisted of five men from each brigade, who had to don hats, coats, and belts, and then run out five 50ft. lengths of hose coiled up, turn on the water, and strike two targets which were placed about 200ft. away. The Robertson Lamp brigade tied for first place, doing the drill in 70¼ seconds, whilst other teams ranged from 76 up to 98 seconds. In all 18 brigades took part in the competition, Manchester, Leicester, and other parts of the country being represented, so that the members of the Robertson brigade may congratulate themselves on the smartness of their performance.

Accident.—An inquest was held on Tuesday at the Dean and Chapter Colliery Offices, Ferryhill, into the circumstances connected with the death of Thomas Lee, who was killed while employed as onsetter at Messrs. Bolckow, Vaughan, and Co.'s Dean Bank Colliery Ferryhill. In the evidence it was stated that deceased received a severe shock while catching hold of a naked "wrapper" wire, which was about 6in. from an electric cable carrying 220 volts in a very damp atmosphere. The jury returned a verdict that deceased was accidentally killed by coming in contact with an electric cable whilst using the wrapper rope, and added the following rider: "That they were of the opinion that cable, wrapper, and other ropes should be kept sufficiently apart from danger, or some other means of complete insulation should be adopted."

Cardiff.—At a meeting of the Electric Lighting Committee on Tuesday, Mr. Arthur Ellis, electrical engineer, submitted a statement with regard to electric lighting for the year ended March 31, 1904, showing that the sum of £11,318 9s. was borrowed from the rates for the purpose of carrying on the undertaking and of this amount, up to the end of March, 1903, £6,599. 1s. 3d. had been repaid. For the year ended March, 1904, a further sum of £2,900. 16s. 11d. was placed to the credit of the rates, which left a balance of £1,818. 11s. 7d. due. The Electricity Committee have decided to contribute £3 000 out of the profits of the current year, leaving a balance of £1,200 above the amount borrowed. In addition, there is a reserve fund to their credit of £2,232, which, if they realised the profit which they had estimated at the end of the year, would be increased to £4,415. 11s. 7d. All temporary loan charges were paid off up to date.

St. Pancras.—The estimated requirements for purposes of the electricity undertaking for the six months ending March 31, 1905, are as follows: engine-room supplies—oil, waste, water, tools, packing, etc., £550; materials, etc., for repairs and upkeep of buildings, engines, boilers, dynamos, and accessories, £1,000; meters and indicators for recording the supply, etc., to consumers' premises, £300; house-service switches, £160; joint-boxes, connectors, etc., for connecting service lines with mains, £100; cables for service lines, etc., £140; general stores, tools, etc., £100; wood casing and capping, creosoted boards, etc., £30; repairs to meters, switches, public lamps, etc., £100; repairs to mains, £600—total, £3,080. The above requirements do not include coal, which is supplied under contract, nor cables and materials required for extensions of supply mains, arc lighting, etc., which the Council may authorise to be carried out, and which would be the subject for a supplementary estimate.

Motor Exhibition.—The Society of Motor Manufacturers and Traders propose to hold a motor exhibition at Olympia in February next. The society have concluded a contract with the proprietors of Olympia whereby the building will be altered and properly fitted up for exhibition purposes, including the wiring for lighting the premises by electricity. It is estimated that the lighting will involve the use of between 10,000 and 20,000 8-c.p. lamps, and the society are prepared to pay at the rate of 4d. per unit for the supply of electricity, and to guarantee a minimum payment of £500 at the first exhibition, which will be held from Feb 10 to 18 next. The society are endeavouring to arrange for a series of exhibitions to be held at Olympia extending over a number of years, and as the building will be fitted up for the purpose, it is probable that other exhibitions will also be held there at which a considerable amount of electric current would be required. The Hammersmith electricity department will, subject to an agreement being entered into by the society, lay a special main at a cost of £1,898 to give the required supply to Olympia.

Western Australia.—The agreement made by the Mayors of Fremantle and East Fremantle, on behalf of the respective municipalities and Messrs. Noyes Bros., of Sydney, for the carrying out of the construction works in connection with the Freemantle electric lighting and tramway scheme, was signed on June 11. The agreement provides that all plant and material shall be ordered by the Tramway Board through Messrs. Noyes Bros.; that within 18 months of the date on which they are authorised to order the first portion of the material Messrs. Noyes Bros. shall have the undertakings, rolling-stock, and plant complete and in full working order, unless delayed by strike, etc. They must at their own cost instruct and organise the operating staff, enginemen, motormen, conductors, and linemen before handing the works over. If the cost of the undertakings should exceed £284,000, Messrs. Noyes Bros. are to pay the amount of the excess to the Tramway Board. The firm is to receive a commission of 10 per cent. upon the amount actually expended in the construction of the undertaking, but the total sum on which commission shall be payable, exclusive of cost of extra work, shall not exceed £76,400.—*N.S.W. Railway Budget.*

Holyhead.—The Urban District Council's electricity and destructor works were opened on Friday last by Lord Stanley of Alderley. Mr. Robert Roberts, chairman of the District Council, presided over a large audience at the town hall. Mr. James Lansbury, chairman of the Electricity Committee, gave a history of the works. Other speakers were Mr. W. D. Jones, one of the pioneers of the movement for the establishment of the works, and Messrs. J. T. Griffiths and J. James. The scheme has involved an expenditure of £16,000, including a two-cell Meldrum refuse destructor, with a complete plant and mains for generating and distributing current on the three-wire system. The Council were fortunate in acquiring a substantially built steam mill for the works, situate in the King's-road, and the building has proved to be eminently suited for its present purpose, with ample room for extensions. The whole of the street-lighting, which was formerly by means of gas and oil, is now to be effected by electricity, and includes 10 arc lamps, with about 240 incandescent lamp standards, the old gas standards having been adapted for the latter. The present contracts provide for 100 consumers, 60 being already connected. Mr. Price F. White, of Bangor, is the consulting engineer for the scheme, and Mr. Philip Williams acted as clerk of works and resident engineer. The contract for the plant, mains, street-lighting, etc., was entrusted to the National Electric Construction Company, Limited, of 34, Victoria-street S.W. Messrs. Meldrum Bros., of Timperley, supplied the destructor plant and Babcock boilers, while the Aphons Custodis Chimney Construction Company, Limited, erected the chimney shaft. After the proceedings at the town hall, a subscription banquet took place at the North-Western Hotel, at which the chairman of the Council presided, supported by Lord Stanley of Alderley, Mr. Ellis Jones-Griffiths M.P., Captain Barr, R.N., Mr. W. B. Cownie (manager, National Electric Construction Company, Limited), Mr. Price F. White, Mr. Moreton Prichard, Mr. John Meldrum, etc., with all the members and officials of the District Council. Mr. Lansbury, chairman of the committee, in responding to the toast of the evening, "Success to the Electricity Undertaking," expressed his satisfaction with the way in which all concerned with the undertaking—consulting engineer, contractors, and clerk of works—had carried out their respective work, and prophesied its early success. Mr. W. B. Cownie, on behalf of the National Electric Construction Company, afterwards presented the two chairmen with silver bowls as mementoes of the occasion. The consulting engineer and resident engineer were also the recipients of mementoes from Messrs. Meldrum Bros. The town generally was *en fête* at night, and if enthusiasm goes for anything, the new undertaking ought to prove a great success.

Refuse Destructors.—An interesting article appeared in the *Liverpool Courier* a few days ago on this subject, and it is of especial value as it relates to the experience of the Liverpool Corporation, whose destructor of 250 tons per day capacity is probably the largest in use in the United Kingdom. Our contemporary says the system of destroying refuse by cremation obtains in about 180 towns, in 63 of which the destructors are combined with electricity works, whilst in 40 towns they are operated in conjunction with sewage works. At Nottingham and Leicester destructors have recently been built on the Liverpool pattern to supply power for electric traction, and Wolverhampton and Preston are about to erect destructors for power purposes. Liverpool was one of the first to see the possibilities of the destructor in the matter of supplying electric current, and at various refuse centres in the city steam is generated on the high temperature system to furnish electric power for the trams. The utilisation of the destructor for this purpose was first attempted for operating the electric tramlines along Smithdown-road. Some little difficulty was experienced in obtaining the requisite power, which was then solely supplied from the generating station in Cleveland-square. An arrangement was, therefore, made to obtain a supply of electricity from the Smithdown-road destructor works for working the outlying length of line, and this entirely met the difficulty. Following upon this the system was extended to three of the other works mentioned, to which has since been added the Garston destructor; so that at the present time five out of the six works are actually engaged in providing

Digitized by Google

steam for electricity purposes. As regards the Rathbone-road destructor, there is as yet no electrical generation. The chief interest would now appear to centre in the Laverock-bank destructor. Here the Corporation have brought to bear all the experience they have gained in the past from the utilisation of steam generated from the burning of the refuse, with the result that a design of the very latest principle was adopted, and an eight-cell destructor constructed. This installation is now in full work, the result being that about 60 units of electricity are being delivered for every ton of refuse sent to the depôt. It will, therefore, be seen that the Laverock-bank destructor is the most important of the installations, as well as the most modern. It should be specially noted that, with one exception, no coal is used at any of the destructors except on a Monday morning to start the firing up. To see what amount of power these destructors are capable of giving, the case of Cobb's Quarry furnishes a capital illustration. This branch has been in existence for about four years. During 1902 the total number of units of electricity sent out from this place for electric traction and electric lighting was close upon one million and a quarter, whilst the sum paid by the Electric Lighting and Power Committee to the Health Committee for the steam to generate this electricity amounted to nearly £21,700. This represents a value in electricity of about 11¾d. per ton for every ton of refuse sent to this destructor during that year, which is a very considerable contribution towards the total working and maintenance of the destructor. The figures relating to the other destructors are not available, but it can be safely asserted that when the works are fully equipped for this purpose the sums paid by the Electric Power Committee for the steam will increase. As regards the output from five destructors for the current year, it is calculated, and given as a fair assumption, that the total number of units of electricity will amount to about 4½ millions, or equal to about 25 per cent. of the whole of the electric current generated by the Liverpool Corporation for tramway purposes, so that their utility in this respect is beyond doubt. If they were not put to this purpose, it would certainly mean the putting down of additional plant at the various electricity generating stations. The municipality of Liverpool again shows its enterprising spirit and its desire to be in the front of other large corporations in all matters which tend to the advancement and the improvement of the city as a whole. It is pleasing to note that the continuous efforts of the Health Committee for some years past are producing results which are enabling objectionable town's refuse to be dealt with so promptly by fire that the materials collected daily from ashpits are disposed of within 24 hours, while the amounts paid to the Health Committee by the Electric Power and Lighting Committee form a very important contribution towards reducing the cost of the cleansing operations of a great city like Liverpool.

PROVISIONAL PATENTS, 1904.

SEPT. 12.

19609. An electromagnetic variable-speed gear for motorcars and other purposes. Arthur George Seaman, 32, Beaufort-road, Kingston, Surrey.

19611. Improvements in controlling apparatus for electric motors. John Klinkenberg, 121, West George-street, Glasgow. (Complete specification.)

19612. An improved terminal for electrical conductors. Alexander Duncan, 132, Stoke Newington-road, London.

19646. Improvements in or relating to electrolytic electricity meters. The Bastian Meter Company, Limited, Charles Orme Bastian, and Charles Henberow Churchill, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

19647. Improvements in chains for pendant electric light fittings. Frederick Charles Smith and Frank Herbert Davis, 128, Colemore-row, Birmingham.

19651. Improvements in electric railways and tramways. James Clarke, 5, Hatton-garden, Holborn-circus London.

19665. Improvements in automatic transmitters for electric fire-alarm or other signals. Harold Hawthorn, 40, Chancery-lane, London.

SEPT. 13.

19685. Improvements in and connected with trolley poles of electric tramcars. James Schofield, 4, Corporation-street, Manchester.

19748. Improvements in or relating to apparatus for supplying alternating electric current. Arthur Francis Berry, 46, Lincoln's-inn-fields, London.

19749. Improvements in or relating to apparatus for use in the distribution of alternating electric current. Arthur Francis Berry, 46, Lincoln's-inn-fields, London.

19762. Improvements in and connected with points for electric tramways and light railways on the conduit system. Richard Ames, 82, Mark-lane, London.

SEPT. 14.

19822. Improvements relating to starting resistances for electric collector motors. Marius Latour, 7, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Sept. 16, 1903, being date of application in France.) (Complete specification.)

19823. Improved means of protecting "live" rails on electric railways. John Joseph Hodgson, 56, Ludgate-hill, London.

19825. Improvements in magnetic inductors. Franklin Wise Howorth, 46, Lincoln's-inn-fields, London. (Adolf Hommel, Switzerland.)

19833. Improvements in or connected with arc lamps. William James Davy, 40, Chancery-lane, London.

SEPT. 15.

19838. A means by which the points of an electrical railway or car line may be operated from an approaching car. Thomas Miller, 15, Partick-hill-road, Glasgow.

19848. Improvements in electric conduit systems. Alexander Gibson Hyslop, 37, West Nile-street, Glasgow.

19883. Improvements in electric igniters. Ernst Eisemann, 6, Lord-street, Liverpool. (Complete specification.)

19885. Improvements in and relating to electric controllers. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

19886. Improvements in electric railway systems employing sectional conductors. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

19887. Improvements in and relating to safety devices for electric signalling systems. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

19888. Improvements in signalling systems. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

19889. Improvements in and relating to electromagnetic mechanism. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

19890. Improvements in and relating to systems of signalling. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

19891. Improvements in protective devices for signal systems. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

19898. Improvements in primary batteries. Harriette Elizabeth Blackburn, 27, Ranelagh-gardens, Barnes, Surrey.

19917. Improvements relating to push-buttons and the like for electric bells and similar services. Edgar Goodwin Harcourt, 18, Southampton-buildings, Chancery-lane, London.

19923. Improvements in electromagnets having polarised armatures for use in apparatus operated by reversals of electric current. Adolf Hommel, 46, Lincoln's-inn-fields, London. (Date applied for under Patents Act, 1901, Dec. 21, 1903, being date of application in Switzerland. (Complete specification.)

SEPT. 16.

19958. Improvements in third-rail systems of electric traction. Edward Everett Clark, 3, Brown-street, Market-street, Manchester.

19961. Improvements in electrically or mechanically controlled driving gear. Henry Vincent James, 3, Brown-street, Market-street, Manchester.

19976. Improvements in systems for the electrical propulsion of vehicles. William R. Everett and Edwin J. Newton, 7, Southampton-buildings, Chancery-lane, London.

19979. Improvements in magnetic wheels. William R. Everett and Edwin J. Newton, 7, Southampton-buildings, Chancery-lane, London.

19993. Improvements in shunts for electrical instruments of the moving-coil type. Evershed and Vignoles, Limited, and Ernest Blacker Vignoles, 1, Queen Victoria-street, London.

19997. Improvements in or relating to apparatus for regulating the voltage of electrical circuits. Harve Reed Stuart, the Westinghouse Patent Bureau, Westinghouse-building, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, Sept. 26, 1903, being date of application in United States.) (Complete specification.)

19998. Improvements in current-collecting devices for electric generators and motors. Karl Fredrik Elers, the Westinghouse Patent Bureau, Westinghouse-building, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, Sept. 26, 1903, being date of application in United States.) (Complete specification.)

19999. Improvements in electrical transformers. Charles le Geyt Fortescue, the Westinghouse Patent Bureau, Westinghouse-building, Norfolk-street Strand, London. (Date applied for under Patents Act, 1901, Sept. 30, 1903, being date of application in United States. (Complete specification.)

20000. Improvements in or relating to coils for electrical apparatus. Charles le Geyt Fortescue, the Westinghouse Patent Bureau, Westinghouse-building, Norfolk-street Strand London. (Date applied for under Patents Act, 1901, Sept. 30, 1903, being date of application in United States.) (Complete specification.)

20001. Improvements in systems of electrical distribution. Paul Martyn Lincoln, the Westinghouse Patent Bureau, Westinghouse-building, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, Sept. 30, 1903, being date of application in United States.) (Complete specification.)

Digitized by Google

20663. Improved process and furnace for subjecting solid materials to the action of the electric arc. Kristian Birkeland and Samuel Eyde, 46, Lincoln's-inn-fields, London. (Date applied for under Patents Act, 1901, Sept. 19, 1903, being date of application in Norway.) (Complete specification.)

20667. Improvements in supports for incandescent electric lamps. Adolphe Romain and Jean d'Ayguesvives, 6, Lord-street, Liverpool. (Complete specification.)

20669. Improvements in and relating to electric telegraphy. Alexander Muirhead, 323, High Holborn, London.

20618. An improved holder for electric lamps. Charles Clare Regnart and the Hunter Electric Candle Lamp Company, Limited, 29, Anson-road, Cricklewood, London.

20619. Improvements in electric arc lamps. William James Davy, 40, Chancery-lane, London.

SEPT. 17.

20629. Effecting the electric propulsion of navigable vessels. Benjamin Howarth Thwaite, 29, Great George-street, Westminster, London.

20670. Improved magnetised board for teaching purposes. Joseph Bohy, 33, Cannon-street, London. (Complete specification.)

20699. Improvements in incandescent glow lamps. Hubert Frank Ashe, 9, Regent-street, London.

20165. Improvements in electrical signalling apparatus for fire-calls and the like. Edward Lawley Pinching and Walter Henry Walton, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Oct. 6, 1904.

1903.

19449. Apparatus for reducing or preventing the production of sparks at the collectors or commutators of dynamos, electric motors, and the like. Thury. (Date applied for under International Convention, Oct. 16, 1902.)

19382. Electric fuses and the like. Baby.

20072. Coin mechanism, especially applicable to electricity and other meters. Du Bois.

21294. Dynamo-electric machines and electric motors. Erik Artur Fagerlund and Allan Ernest Messer.

21551. Switches for use for electric lighting and power. Quaney and Kirwan.

24630. Current-collecting devices for electric railway vehicles. Shaw.

24800. Electric braking systems. British Thomson-Houston Company, Limited. (General Electric Company.)

26772. Electric arc lighting. Carbone.

1904.

7642. Electric fuses. Lee.

8216. Electric furnace for converting pig iron into steel. Gin. (Date applied for under International Convention, June, 4, 1903.)

10430. Electric cables. Whalley and Bayles.

13433. Process and apparatus for cleaning out electric accumulator batteries. Hicking.

13779. Electrical distribution, particularly applicable for controlling electric motors. Dunn. (Date applied for under International Convention, June 18, 1903.)

14529. Branch connections or couplings for electric cables. Everhart and Dossert.

15441. Automatic firing apparatus for guns having electrical or electro-mechanical ignition. Pechy and Rea.

15468. Vapour electric lamps, rectifiers, and the like. Weintraub. (Date applied for under International Convention, July 11, 1903.)

16762. Method and means for joining together the ends of telegraph wires and the like. Schmidmer.

17339. Electric switch. Heys. Meyrowitz Manufacturing Company.)

17493. Transmitter for electric telegraphs. Potiewski.

NOTES.

Cable Concession.—The *Daily Mail* states that a German company has succeeded in obtaining from the Porte a concession for the submarine cable between Constantinople and Constanza (Roumania), which will be connected with Berlin and Bagdad. This result was secured despite all the efforts of the British Embassy to support the rights of the Eastern Telegraph Company, which has a monopoly for all submarine cables in Turkey.

Rugby Engineering Society.—The annual general meeting will be held in the Benn-buildings, High-street, Rugby, on Thursday next, at eight o'clock, when the following business will be transacted: election of officers and members of council; ballot for day of meeting; president's report for session 1903-4; and alteration to Rule 10, *re* auditors. After this, there will be a discussion on the metric system, which will be opened by Mr. E. R. Briggs, hon. recording secretary, and replied to by Mr. R. C. Jackson. Members may obtain copies of the opening remarks after to-day.

Tramways and Light Railways Association.—In the Official Circular for September are given the model by-laws regulating the stopping, etc., of tramcars; the last Board of Trade regulations under the Electric Lighting Acts, and under the provisions of special Tramway Acts or light railway orders. It is also notified that the following lectures will be given at the Society of Arts, John-street, Adelphi—viz.: "Automatic Regenerative Control for Electric Traction," by Mr. J. I. Hall, on Oct. 20; "Notes on Permanent Way," by Mr. A. N. Connett, on Nov. 3; and "Running Powers," by Mr. Stephen Sellon, in December; and that members of the association have been invited to visit the various works of the London County Council tramways on Nov. 11.

Motorcar Speed Limit.—The Local Government Board conducted an enquiry at the Guildhall on Tuesday into the speed at which motorcars should be allowed to travel through the City. Sir Homewood Crawford, on behalf of the City Corporation, contended that a limit of 10 miles an hour should be fixed. Major Nott-Bower, Commissioner of Police, considered even this "almost too high." A quantity of evidence was tendered for and against, one member of the Court of Common Council declaring that the professional chauffeur "is the curse of London"; while Mr. J. R. Nisbet, of the Motor Union, produced statistics to show that in the roll of fatalities in the Metropolis the motor played an infinitesimal part. The Automobile Club and the Motor Union were represented by counsel.

The Cable to Iceland.—It is announced that the negotiations have now been concluded between the Great Northern Telegraph Company and the Danish Government for the establishment of a cable from Iceland to Copenhagen. The company pays all the expenses of the cable, which is to be ready in two years. The Danish and Icelandic Governments will allow a subvention of £5,000 a year for 20 years to the company. Permission has been obtained from the British Government to land a cable in the Shetland Islands, and this will be in communication with the existing cable from Shetland to Scotland. The cable from Shetland will be laid *via* Thorshavn, in Faroe, to the east coast of Iceland. Thus Iceland will again have a main line from the east coast to its capital, Reykiavik. The company is to commence the work immediately.

New Publications.—"Central Electrical Stations: Their Design, Organisation, and Management," by C. H. Wordingham (London: Chas. Griffin and Co. 24s.). This is the second edition of this valuable treatise, which describes the scientific, engineering, and commercial problems arising in the practical operation of central stations, and offers solutions to them from actual experience. "Elementary Manual on Applied Mechanics," by Prof. A. Jamieson (London: Chas. Griffin and Co. 3s. 6d.). The continued popularity of this work has induced the author to publish a sixth edition, in which have been included the question papers for stage 1 of the Board of Education and other examinations. Messrs. Harper and Brothers are about to publish "The Diseases of Electric Machinery: Their Symptoms, Causes, and Remedy," by C. Kinzbrunner. Price 1s. 6d. This manual could not well be in a more succinct form, as the subject is dealt with throughout in three parallel columns under the headings "Symptom," "Cause," and "Remedy," and it should prove very serviceable to those in charge of either continuous or alternating current generators or motors.

Electricity and Therapeutics.—A letter appears in the *Liverpool Courier* from Mr. R. W. Mackenna, in which he takes the Corporation of that city to task for refusing to supply the hospitals with current for the Finsen treatment at power rates and insisting upon the usual scale for light, the result of which, he states, is that the hospitals resort to a modification of the Finsen apparatus, which modification, though giving excellent results, is not so efficacious as the original treatment. The essence of the differential charges for light and power is the fact that the latter is used fairly regularly for a number of hours, while for lighting current is only required during the periods of darkness. The current required for the Finsen cure is certainly, as the nature of the treatment necessitates, converted into light, and even in hospitals devoted to this treatment the load factor is not, we think, large. In smaller hospitals, where the use of current for this purpose is intermittent, the load factor becomes worse, and we think that the ordinary lighting rates are not excessive. We certainly cannot agree with Mr. Mackenna that the charge for current is the chief obstacle to the introduction of the Finsen lamp into Liverpool hospitals.

The Relation between the Pressure and the Discharge Voltage in Exhausted Tubes.—In a note to the Academie des Sciences, M. Séguy describes some experiments on this subject. It is well known that as the vacuum is pushed to an extreme limit the voltage required to speak across a given distance increases rapidly. So long as the pressure does not fall below $\frac{1}{100}$mm. the McLeod gauge can be employed for determining it, but below that pressure the gauge is useless. M. Séguy considered that by deciding the relation between the pressure, p, and the length of spark-gap, d, corresponding to the discharge in the tube down to the limiting point, the relation for lower pressures could be determined by extrapolation, and the spark-gap distance could then be employed as a measure of these very low pressures. He therefore arranged a micrometer spark-gap in parallel with a tube fitted with a McLeod gauge, and obtained the following results:

Spark-gap distance, d, in mm.	Measured pressure, p.
1	·1320
3	·0660
5	·0330
7	·0165
9	·0082

It will be seen that as the spark-gap distance increased in an arithmetical progression, the pressure, p, decreased geometrically; p is, therefore, an exponential function of d,

Digitized by Google

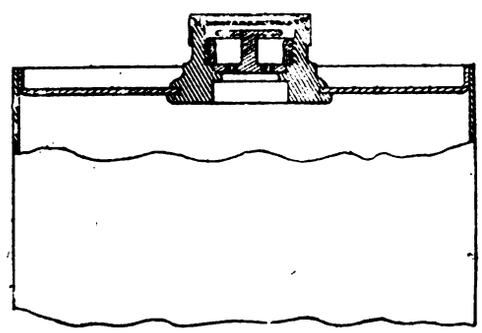
and lower pressures can be arrived at by measuring the corresponding spark-gap distances with a micrometer.

Transmission and Distribution Problems Peculiar to the Single-Phase Railway. — This subject was dealt with in a paper presented to the International Electrical Congress by Mr. P. M. Lincoln, for the following abstract of which we are indebted to the *Electrical World*: An apparent handicap for the single-phase in comparison with the three-phase transmission system is the fact that the copper required is in the ratio of 4 to 3. This ratio holds true on the basis of equal potential between wires, but if equal normal potential to ground be considered the basis, then the single-phase and the three-phase are on an equality. A polyphase generator is cheaper by 30 per cent. than a single-phase machine of the same capacity; hence it is advantageous to use polyphase generators for supply, dividing the load as equally among the phases as possible. A disadvantage is found in thus operating from a polyphase circuit, since if one of the three wires be taken away, the sum of the static potentials no longer remains at zero, and static induction will take place on neighbouring (telephone) circuits without the possibility of correction by any method of transposition. After discussing the application of Kelvin's law for the determination of maximum commercial economy of conducting material and the relation of the voltage drop to the spacing of transformer stations, the author concludes that there is no golden rule for the determination of the spacing and capacity of transformer stations or of the size of the conductor. It is a matter of compromise between various elements, some of which point in one direction and some in the other, and is a matter which must be determined by engineering judgment rather than by any inflexible law.

Electric Power for Oil Wells.—Mr. M. L. Gaster has tabulated some facts regarding the use of electricity in connection with petroleum production. The demand for petroleum greatly exceeds the present production. The substitution of oil for coal, in order to be advantageous, needs a better regulation of the methods of producing it, and also of the price. In this connection the use of electric motors is a question of great interest. Mr. Gaster considers that the employment of electricity, which is generated in a large central station, to operate motors for petroleum wells is justified by the area covered by the wells, as well as by the fact of the danger from fire caused by the steam-engines which operate the drills and pumps. A central-station system also has the advantage of being able to cope with the variations of load at the different wells. Electric motors were first used for drilling wells some five or six years ago in Roumania. The plant was provided with a set of motor-driven pumps. A central station was erected at a distance of 1½ miles. The motors are of the three-phase type, operating at 300 volts. The total capacity of the station is 200 kw. Later, the Lahmeyer Company erected a large station for working the wells at Campana and at Bushtenari. The first cost of the plant was £500 per well, and the running expenses £8 per horse-power year. In Russia, which is the greatest petroleum-producing country, the conditions are less favourable to the use of electric power, owing to the fact that the oil consumed to furnish the power for the wells is not subject to any tax, and therefore a very cheap supply of energy can be had. It is to be noted, however, that a large number of electric plants have latterly been installed in that country.

New South Wales.—The annual report of the Commissioners on the New South Wales railways and tramways for the year ending June 30 has come to hand promptly. In regard to the railways, the receipts amounted to £3,436,413, against £3,314,893 during the previous year; the expenditure decreased from £2,266,299 to £2,258,940; and the balance represented £1,177,473 against £1,048,594. The mileage opened for traffic totals 3,280¾, and the amount spent on construction and equipment aggregates £42,288,517. The number of miles of tramway line opened for traffic at the date of the report was 125¾, the amount spent on construction and equipment totalling £3,471,759. Several new sections were opened during the year, and in the capital the forms of traction other than electric are rapidly disappearing. There was only an increase of 1¼ miles over the previous year in the length of line available for traffic, but the receipts rose from £752,034 to £802,985. The expenditure amounted to £673,625, against £654,165, leaving a balance of £129,360, against £97,869. The receipts per mile averaged £6,398, and the earnings per car mile 11¾d., against working expenses of 9¾d., showing a profit of 2d., against 1¾d. during the previous year. The passengers numbered 137,843,513, against 130,405,402, and the total mileage amounted to 16,387,019, against 13,695,630. The plant at the Ultimo power-house worked satisfactorily throughout the year, and is now being extended by the addition of a 1,875-kw. turbo-generator, the power from which will be applied to the conversion of the Ocean-street cable line and the remaining steam lines connected with the city system, and also to enlarging the existing services in order to meet the increased traffic requirements. Additions are also being made to the sub-stations.

Non-Explosive Storage Battery.—A method of rendering storage battery gases non-explosive has been patented by Mr. Thomas A. Edison, who has assigned the patent to the Edison Storage Battery Company. A description of the apparatus, with the accompanying diagram, appears in the *Electrical Review* of New York. The case, which is made of thin nickel-plated steel, is provided with a neck having a perforated plug, and carried by this plug is a deflecting plate for diffusing the gases escaping through the perforations. At the top of the neck is a suitable cooling medium through which the gases pass. When the apparatus is not provided with special means for effecting



the separation of the mechanically-entrained globules, the gases will escape continuously through the perforations in the plug, but if separating devices are employed the gases will escape intermittently through these perforations. The escaping gases will be deflected outwardly by the deflector, so as to be comparatively attenuated, and they will escape through the cooling medium in a highly rarefied condition. Even if they could ignite on the outside of the medium, the radiating capacity of the latter is sufficient to prevent it becoming hot enough to ignite the gas below it, so that no explosion can take place. This is especially true when the deflector is used; otherwise there would be danger of a small stream of gas passing directly from each perforation through the medium in a sufficiently concentrated condition to result in the gauze being dangerously heated.

Unaccounted-for Current.—At the tenth annual convention of the Ohio Electric Light Association last

Digitized by Google

month a paper on this subject was presented by Mr. W. E. Richards, in which he pointed out the several sources of lost current. The most important of these he stated to be that which occurs at the meter in the shunt circuit and through meters running slowly. In direct-current watt-meters the shunt loss runs approximately 35 to 175 kilowatt-hours per year, and in the induction type from 17 to 35 kilowatt-hours per year. A table given by the author showed that the loss in a commutator type of meter, after having been in use 21 months, was 37 per cent. at one-twentieth load, 18 per cent. at one-tenth load, 8 per cent. at quarter load, 3·5 per cent. at half load, 2·2 per cent. at full load. Even with the precaution of installing meters of a capacity as near the lighting load as possible, data collected show a loss of from 12 to 18 per cent. on one-tenth load, and 5 to 8 per cent. on quarter load. Mr. Richards remarks that meter losses in unaccounted-for current can be reduced to a minimum only by an intelligent effort of the meter department, as upon the care and upkeep of the meter depends at least 10 per cent. of the earnings of the company. The author recognises as a practical step the systematic cleaning and inspection of meters, the interval between such cleaning and inspection depending on the capacity and service. To reduce the controllable losses on a meter system, of course, requires additional expense. Just where the balance of the additional expense and the reduction of the losses occur is a fine point to decide. If the meters are of the induction type, Mr. Richards's practice is to give them attention every 18 months, but the commutator type requires an inspection every 8 or 12 months.

Municipal Electrical Association.—It will be remembered that at the annual general meeting, held at Derby on July 2, and duly chronicled in these columns, it was reported that the membership had increased to 387. The *Proceedings* of the association are just to hand, and contain various other points worthy of recapitulation. Mr. Wilmhurst remarked, in the course of his presidential address, that in the first year of the association's existence its members controlled undertakings with a capital outlay amounting to £4,000,000, and now, within eight short years, the figure had risen to nearly £40,000,000. He concluded by exhorting members to support the work of the Engineering Standards Committee. The papers presented consisted of "The Commercial Practicability of Electric Traction by Surface Contacts," by C. E. C. Shawfield; "The Organisation and Management of a Central-Station Meter Department," by A. J. Cridge; "Polyphase Sub-Stations: Their Equipment and Working," by S. L. Pearce; "Notes on the Bristol Electricity Fire," by H. Faraday Proctor; "Boiler-House Economies," by R. S. Downe; "The Financial Position of Municipal Electrical Undertakings," by J. R. Blakeway; and "Steam-Turbines: Their Efficiency compared with Reciprocating Engines," by H. Howard, the last-named being the associates' prize paper. There was a very limited entry for this prize, and the association hope that there will be a better response in future. In the course of the year the Parliamentary Committee considered a number of electrical measures, and especially the Supply of Electricity Bill, taking steps to ensure that the objections it had raised would receive attention. The balance-sheet showed a small deficit. As the treasurer's report observed, the association does not exist for the purpose of making a profit, but it ought to make both ends meet. The election of officers for the ensuing year resulted in the choice as president of Mr. F. A. Newington, Edinburgh, where the next annual convention is to be held. At a special meeting the articles of association were altered so as to facilitate qualification for the different grades of membership, full particulars of which appeared in our issue of July 8.

Obituary.—In the passing of Niels Ryberg Finsen, at the age of 43, science loses a distinguished votary, though his discoveries remain to ameliorate the lot of suffering humanity. His name will always be associated with the light cure of lupus, but he had a varied gift for invention, and devised, among other things, an improved breechloader, a cool summer-house, a cooking apparatus, and some hæmatine lozenges. It is interesting to note what prompted his researches into the curative properties of light. Finsen heard that during the American War of Independence some prisoners suffering from small-pox were shut up in dark rooms. It was noticed that these men had no secondary fever, that there was no matter in the pox, and that no scars were left by the disease. It had been pointed out by Prof. Widmark that the chemical rays of light, the blue violet and ultra-violet rays, inflamed the skin. Finsen devised a method of using light from which these rays had been removed. This was known as the red or negative light treatment, and has been widely used with beneficial results for small-pox and other affections. While it does not cure small-pox, it prevents the secondary fever. This led to his great achievement in evolving the positive application of light. It occurred to him that by the concentration of light upon the diseased spot of the body, and applied perhaps for a long period, it might be possible to destroy the bacteria which caused the terrible corroding diseases. He put the matter to a test by using an ordinary magnifying glass, cooling the rays in a sphere of glass filled with water. The patient, who had suffered from lupus for eight years, was cured. With the assistance of friends and the Danish Government, the Finsen Institute was founded, and some 2,000 patients have been treated there from all parts of the world. Finsen early discovered that concentrated sunlight or the usual electric lamps were not powerful enough to yield the best results. He experimented with lamps of various powers, and those now in use are of 50 amperes and 45 volts, which kill in a second microbes which will resist daylight for hours. He was awarded the Nobel prize of 100,000 crowns (about £5,500), a large portion of which he devoted to the institute. It is of interest to recall the fact that it was due to Queen Alexandra's appreciation of the Finsen treatment that the cure was introduced into this country. Her Majesty presented the first lamps to the London Hospital, and thus inaugurated a most successful department, which has clearly shown the value of the treatment to English medical men. Although his system of therapeutics did so much for the relief of others, Finsen himself had been a martyr for the past 20 years to a malady of the heart, and the conditions under which he pursued his beneficent work partook of the heroic.

Starting Devices for Mercury-Vapour Lamps.—One of the features of the vapour-electric apparatus invented by Mr. P. C. Hewitt three years ago was the well-known "starting band" in proximity to the negative electrode. The band was located outside the container, within which both the positive and negative electrode of the apparatus were enclosed. Mr. Hewitt has since found that the function of the starting band will be performed whether it is located outside or inside the material constituting the negative electrode, and he has accordingly patented a device (described in the *Western Electrician*) embodying a starting band which is internal with respect to the negative electrode. The invention is illustrated in the accompanying diagrams. Figs. 1 and 2 are vertical sections of different forms of the invention. Naturally, the apparatus may assume many forms, and those illus-

Digitized by Google

trated are simply given as typical. In the diagrams (1) is a container, within which are electrodes (2) and (5), connected respectively with leading-in wires (7) and (8). The positive electrode (2) may be of iron or some other suitable substance, while the negative electrode (5) may conveniently be of mercury, or some material which will undergo disintegration by the action of the electric current, which disintegrated portions will eventually return and re-form as the electrode. In proximity to the negative electrode, and usually projecting somewhat above the level of the upper surface, is placed a starting band (9), which in Fig. 1 is represented as a strip of metallic foil, or may consist of a metallic paint, either in the form of a complete ring or in the form of one or more strips of foil or paint. The starting band (9) in Fig. 1 is internal with respect to the material of the negative electrode, by reason of the fact that the container is made of re-entrant form at the bottom, and

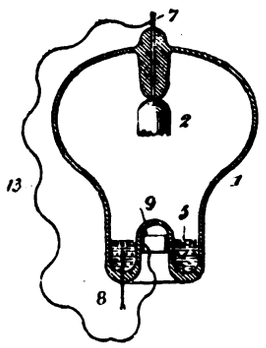


FIG. 1.

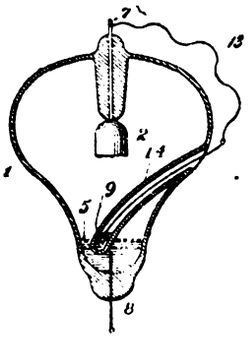

FIG. 2.

the starting band is applied to the inner side of the re-entrant portion in substantially the position indicated in the diagram. In Fig. 2 is shown a tube (14) running in from the outer wire of the container (1), and dipping slightly below the surface of the mercury or other materials constituting the other electrode (5). In this instance the starting band is in the form of a drop of mercury in the bottom of the tube (14), it having been found that this form of starting band operates well in practice.

Iron and Steel Institute.—In accordance with previous announcements, the autumn meeting will be held in New York on Monday and Wednesday, Oct. 24 and 26 next, for which occasion the following papers have been offered: "Iron and Steel at the St. Louis Exposition," by Prof. H. Bauerman; "A West African Smelting-House," by C. V. Bellamy, with an appendix by F. W. Harbord; "The Influence of Carbon and Phosphorus upon the Strength of Iron and Steel," by H. H. Campbell; "The Rateau Low-Pressure Turbine at Steelworks and Collieries," by E. Demenge; "A Dry-Air Blast Apparatus," by James Gayley; "High-Speed Tool Steels," by J. M. Gledhill; "The Determination of Carbon and Phosphorus in Steel," by Baron H. Jüptner von Jonstorff, Andrew A. Blair, Gunnar Dillner, and J. E. Stead; "Acid Open Hearth Manipulation," by Andrew McWilliam and W. H. Hatfield; "A Power-Gas Plant for Johannesburg," by P. J. Mallmann. The following is an outline of the programme for this meeting. The headquarters will be at the Hotel Astor, New York, where the majority of the members are expected to arrive by the 23rd prox. On the following day the opening of the annual general meeting will be preceded by visits to places of interest in the city, and succeeded by a reception, at which addresses of welcome will be delivered, and the Bessemer gold medal presented to Mr. Carnegie in recognition of his great services. The following day will be devoted to an excursion up the Hudson River. On the Wednesday the general meeting will be resumed, and in the evening the institute will entertain the Reception Committee to dinner at the Waldorf-Astoria Hotel, whilst a theatre party is to be arranged for the ladies accompanying the members. After this the party will leave for Philadelphia, visiting various places of interest in that city, and will then proceed to Washington, where, on the 29th, they will be received by President Roosevelt. The 31st will see the party at Pittsburg, and after spending a couple of days in examining iron and steel works, a move will be made for Cleveland. Buffalo will be reached on Nov. 5, and a visit paid to the Niagara Falls. There will be an opportunity for those desiring to inspect the General Electric Company's plant to do so by breaking the journey between Cleveland and Buffalo at Albany. The party will leave New York for England on Nov. 9. For the convenience of members desiring to visit the St. Louis Exhibition, arrangements will be made for a limited number to leave Pittsburg on Thursday, Nov. 3, returning to New York in time for the steamer leaving on Nov. 12. The estimated cost of the circular trip is £25; of the St. Louis excursion £35. The arrangements for ocean transport have been placed in the hands of Messrs. Thos. Cook and Son, who have secured for members the advantages of special rates. Further details may be had on application to the institute.

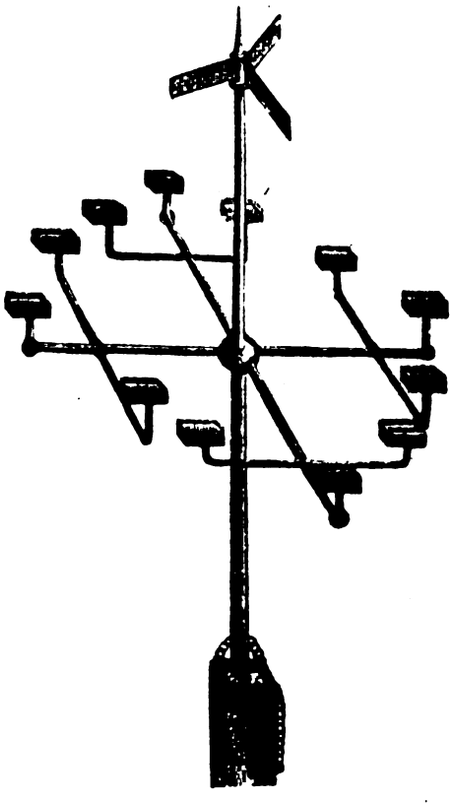
The American Tour.—The cordial welcome promised to visitors of the American Institute is being amply fulfilled, and our Transatlantic friends are showing themselves indefatigable in the entertainment of their guests. The English party landed at Boston on the 2nd inst., and confessed to an exceptionally pleasant trip, save for apprehensions of a tedious process with the Customs authorities, which were speedily dispelled by the co-operation of the Reception Committee, and these little troubles were disposed of in summary fashion. The visitors were promptly conducted to the sports ground, where a novelty awaited many of them in the form of a baseball match. In the evening there was a reception by the local committee, and the Governor of the State welcomed the English and Italian institutions to the birthplace of Franklin. The next day was spent in exploring Boston, after which the party left for New York. An excursion up the beautiful Hudson was followed by a visit to the City Hall Station of the Interborough Rapid Transit Company, whence a pioneer train of eight cars—some of the all-metal construction—conveyed the party at varying speeds to the Columbus Circle Station at Fifty-ninth-street, ample opportunity being afforded of noting the construction of the track, cars, signals, and stations. From this point the party inspected the company's new power-house, and subsequently visits were paid to the power-houses of the New York City and the Manhattan Elevated Railway Companies, whilst in the course of the day the New York City Fire Department treated the travellers to a splendid exhibition of fighting the flames from the river front by one of its largest fire-boats. The stay in the capital concluded with a reception at the Waldorf-Astoria. Early on the morning of the 6th the party hied off to Schenectady, where the General Electric Company gave the party a trip over the new single-phase system to Ballston. The next day saw the party at Montreal, where they visited several places of interest, followed by a reception at McGill University. A visit to the plant of the Shawinigan Falls Water and Power Company, at Shawinigan Falls, some 70 miles from Montreal, was the chief feature of the second day's programme in the Dominion. Higher even than those of Niagara, the falls have not the same volume behind them, but with the present equipment they supply 15,000 h.p. with an 84-mile transmission, and the company is now conducting opera-

Digitized by Google

tions to increase the production by 20,000 h.p. The party then moved on to Niagara itself, where the visitors were enchanted with the scenery. Besides viewing the falls, the various power-houses were duly inspected, and the local committee presented each of the party with a handsome souvenir volume. Chicago was reached on the 9th, and here the party were welcomed by Mr. Samuel Insull, while a couple of days later they arrived at St. Louis, in time for the International Electrical Congress, concerning which we shall have more to say in our next issue.

A New Phonographic Principle.—The magnetic phonograph due to Poulsen has lately aroused much sensation, not only on account of its exceedingly pure rendering of the human voice, but, in the first place, because of the originality of the underlying principle. Instead of using, like Edison, the mechanical deformation of soft masses, as produced by sound waves, for recording the corresponding sounds, Poulsen utilises, so to speak, the magnetic impressions produced in a substance magnetically deformable (steel) under the action of microphone currents. Now, it will be evident that, generally speaking, any phenomenon giving rise to a permanent alteration proportional to the effect of the sound waves may be used on the phonographic principle. When resorting to the electrification of insulators, an electrostatic equivalent of Poulsen's electromagnetic apparatus would evidently be obtained. The above reflections a short time ago induced Prof. W. Nernst, the well-known scientist of Göttingen University, to construct an electrochemical apparatus, utilising the permanent alterations produced on an electrode by galvanic currents—*i e*, galvanic polarisation. The following arrangement was chosen: An endless platinum band, running over two rollers and receiving a permanent movement from a motor, is galvanically polarised by microphone currents. As it is important to comply with the condition that the variable polarisation produced by current oscillations should be separated locally, the platinum band should, on the one hand, be displaced with sufficient rapidity, and there should, on the other, be a point of contact as narrow as possible between the band and the electrolyte. The latter condition is satisfied approximately by using as electrolyte a wood wedge soaked with a conductive liquid and placed in a glass tank filled with the liquid in question and fitted with an electrode. The experiment, as stated by Nernst, will succeed perfectly. A more or less distinct rendering will, it is true, be noted according to the kind of electrolyte used. The sound record may be reproduced several times repeatedly before any appreciable diminution of the sound intensity is noted. The remarkable statement is made that during the reproduction a current should traverse the telephone circuit, the reproduction being the stronger as the intensity of this current is greater. In order to control this current, a variable E M.F. may be inserted into the circuit. The phenomenon obviously fails to be accounted for on the hypothesis that the currents setting up the sound vibration in the telephone during reproduction are merely discharge currents of a polarised electrode; a similar discharge should occur also with no current, while a constant current would not be able to exert any appreciable effect. The experimenter, therefore, suggests that the oscillations in the microphone currents result in a superficial loosening of the metal electrode, passing on the electrolyte; during reproduction there will arise oscillations in the constant current, causing the telephone to vibrate and depending on the loosening referred to above. The apparatus allows in many cases of a rather distinct and even sufficiently loud reproduction of spoken words, though its practical possibilities are evidently inferior to its theoretical interest.

Procopius Diviss.—Who was he? the reader may ask. Some light is thrown upon the question by Dr. J. Rudis-Jicinsky in the *Western Electrician*. Diviss was a doctor of philosophy and theology, and was born in Moravia in 1696. He made his first electrical experiments in 1728, and at that early day he thought that an electric spark might be a good stimulant for certain lesions or diseased tissues of low vitality. For several years he delivered lectures, accompanied by experiments, on physics at the University of Salzburg, where he remained in constant study and research until 1735. In 1741 Diviss was appointed superior of the institute for priests in Luce, on account of the war with Prussia, but on its cessation he returned to the village of Primetice, near Znojmo, to prove beyond doubt, several years before Franklin, that "the electrical stream, not being exactly a fluid, was identical with the lightning." After many efforts he completed his first lightning-rod on June 15, 1754. This apparatus, illustrated in the accompanying diagram, consisted of an iron rod, 1½in. thick and 24 yards high, fastened on to the top of a heavy wooden pole. Iron chains ran down the side of this pole, connecting the metal rod with earth.



Four horizontal iron arms projected from the rod, and to the ends of these arms were fixed smaller arms, attached to which were little boxes covered with iron plates, and having at the edges many iron nails pointing towards the sky. On one occasion he gave a demonstration at Vienna before Francis and Maria Theresa, who bestowed gold medals upon him; but the German and Austrian scientific institutions could not realise his principles, and his communications were received with derision, whilst his one-time tutor besought him to discard such occult practices. Two or three years later the authorities sided with some farmers at Primetice, who attributed an unfavourable summer to the influence of Diviss, and so depressed was the scientist at this incident that he withdrew from further research, and died in seclusion shortly afterwards. His lightning-rod can still be seen at the museum of Bruk. The encyclopædias know nothing of Procopius Diviss, but he prepared the way for the practical application of electricity, and his name should not be forgotten.

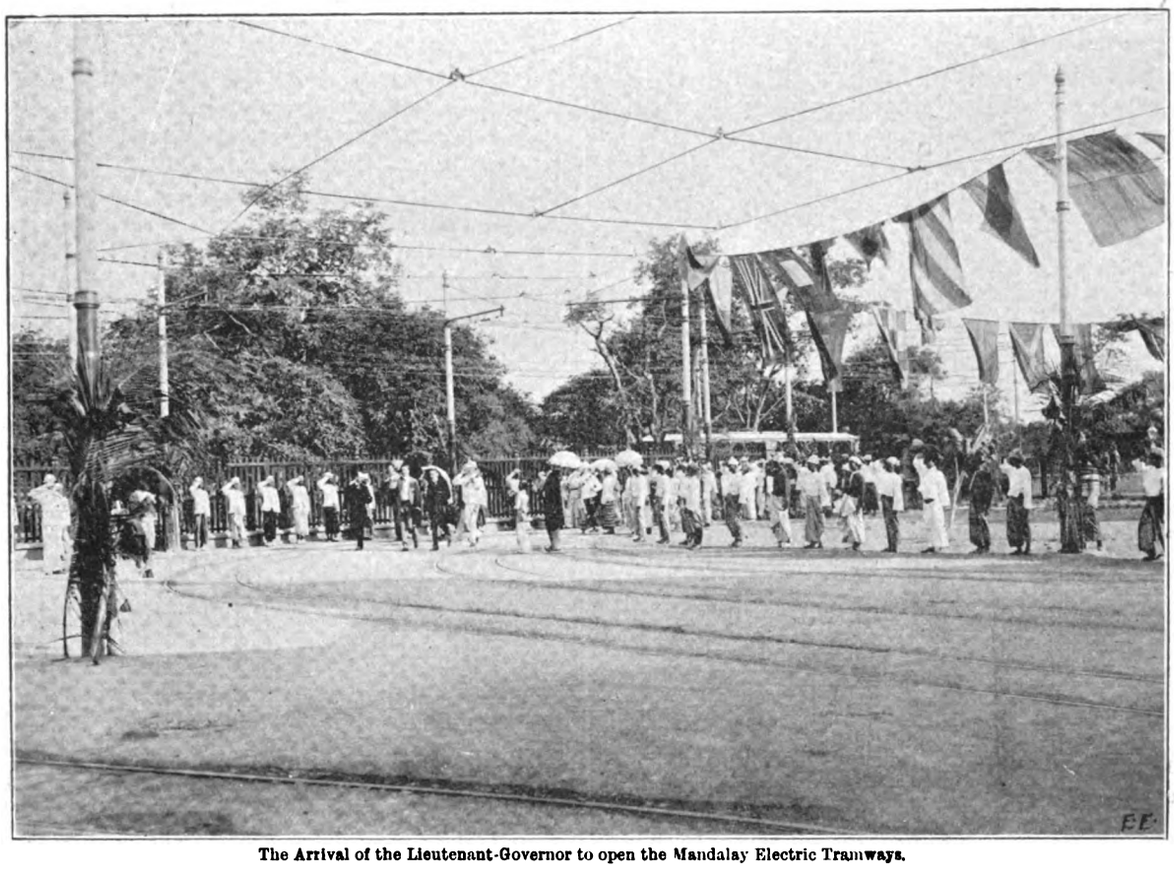
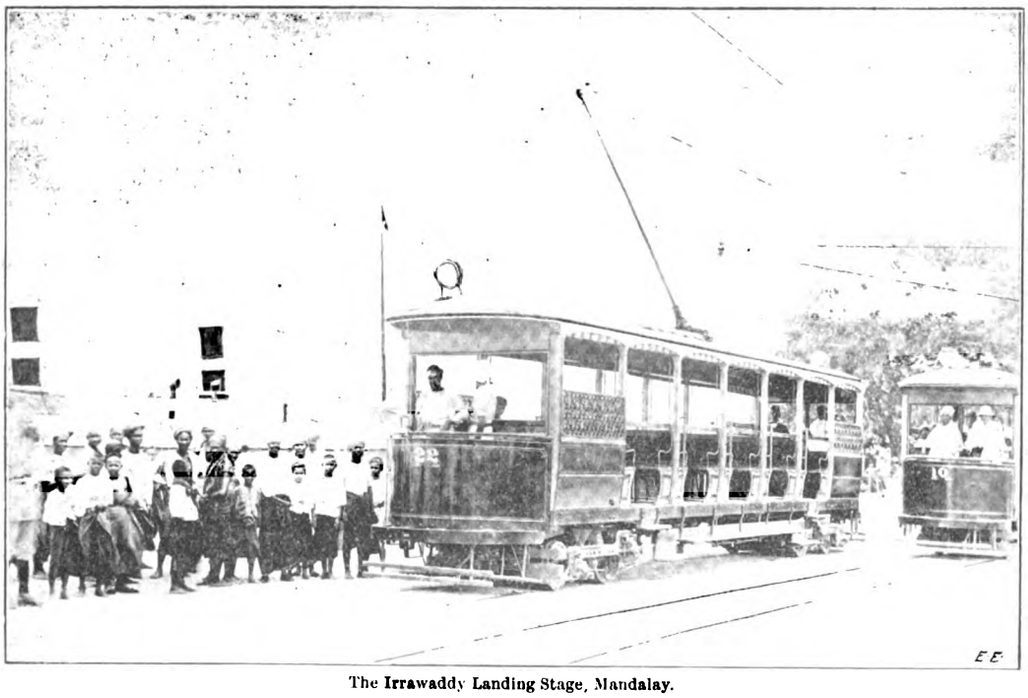
ELECTRIC TRAMWAY IN MANDALAY.

A few weeks ago a short announcement was published in our journal relating to the opening of an electric tramway system in Mandalay by the Lieutenant-Governor of Burma, Sir Hugh Barnes, K.C.S.I., K.C.V.O. Now that the system has been in successful operation for the last two months, and in view of the fact that Mandalay is the first city in Burma to adopt the very latest mode of transit in the shape of electric cars in place of horse traction, a detailed description of the enterprise will no doubt be of interest.



The Arrival of the Lieutenant-Governor to open the Mandalay Electric Tramways.

The Mandalay Electric Company was floated in London in October, 1902, with a capital of £200,000. Actual work was commenced in December of the same year by the contractors, Messrs. Dick, Kerr, and Co., Limited, and within the short space of a year and a half the first car was moved by electrical power on June 17, 1904. The centre of the tramway system has been wisely placed at the new Zegyo Bazaar, on which the municipality is spending a large sum of money, and which promises to be, when finished, the largest bazaar of its kind in the East, and a position that will become a centre of attraction to the Burmese from all parts of the city. From the Zegyo Bazaar the tramway radiates in three branches. One leads to the shore, where the Irrawaddy Flotilla Company's steamers embark their passengers, and so will cater for the travelling public. The second runs to the Arakan Pagoda, and will serve the suburbs which cluster round that famous shrine. The third leads to the Court House, where the daily legal business of the city and district is transacted, and to which a certain number of citizens would always

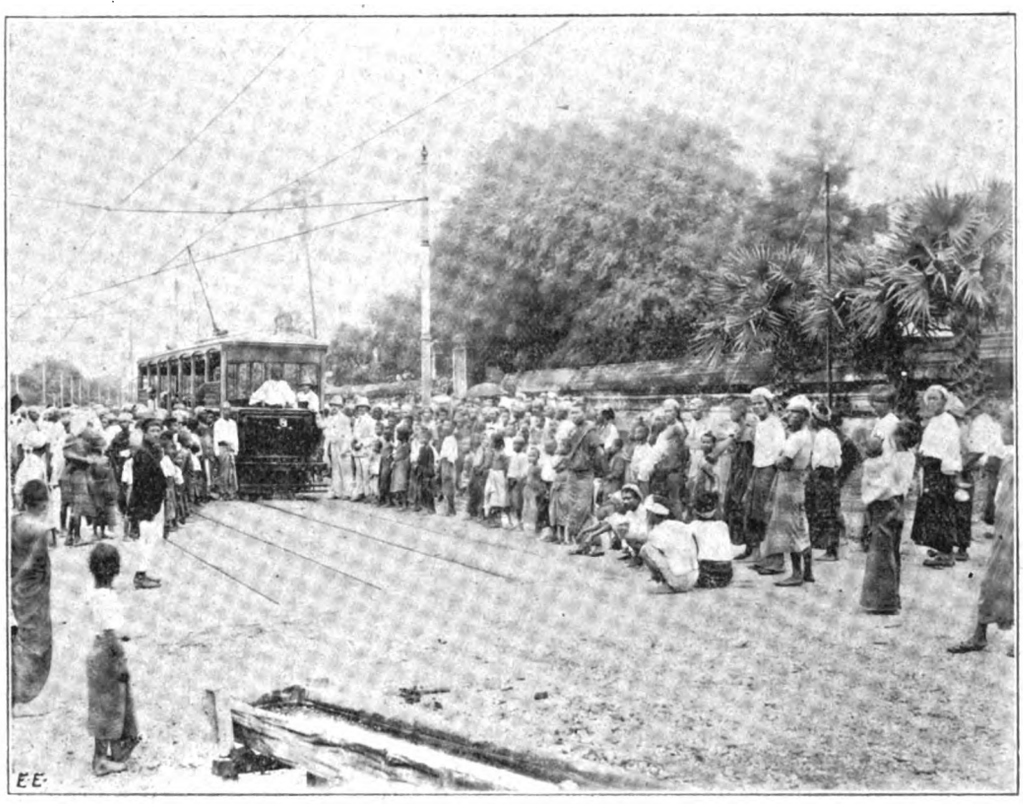


The Irrawaddy Landing Stage, Mandalay.

Digitized by Google

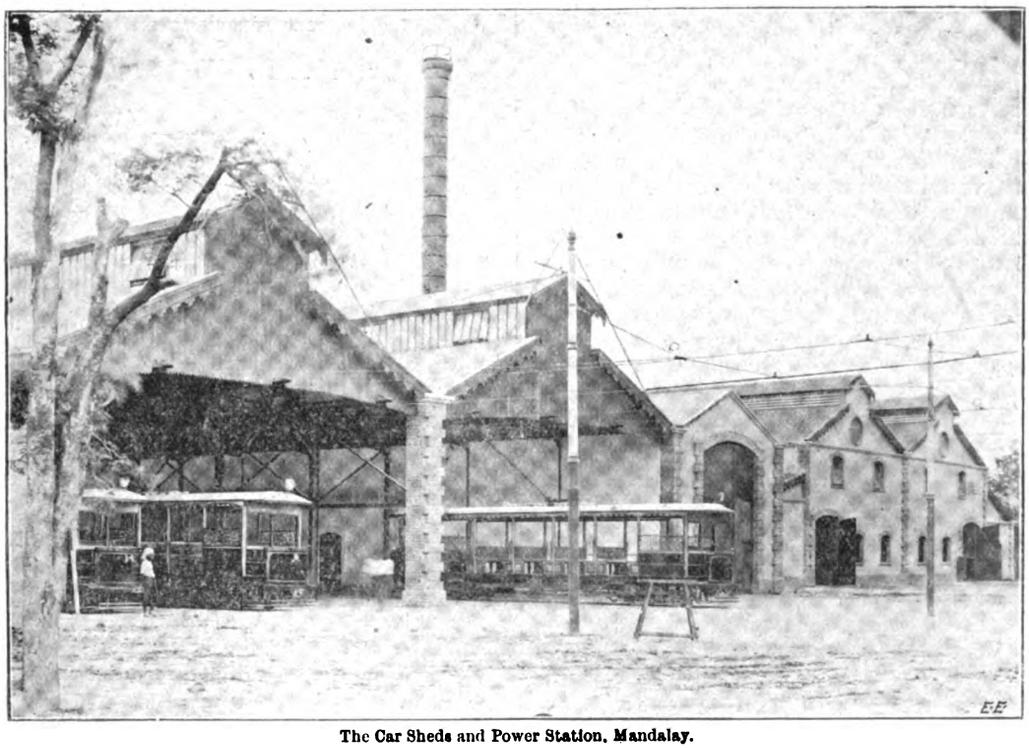
desire to resort, and so would use the tramways for that purpose.

The tramways have a route length of seven miles, double track throughout, and equals, exclusive of cross-over roads, approximately 14 miles of single track. The rails are in



The Pyagyi Terminus of the Mandalay Tramways.

accordance with standard tramway practice, 6in. deep, with a 1¼in. groove, laid to a gauge of 3ft. 6in., in 45ft. lengths, with a proportion of shorter lengths to allow for piecing in and closures. The rails are double spiked to hardwood sleepers, which are laid at 2ft. 9in. centres, the whole being



The Car Sheds and Power Station, Mandalay.

laid on a ballasted bed, the road surface being made up with macadam in the ordinary way. The joints are of the plain type, and are secured with six-holed fishplates, and are double bonded with two 4/0 B. & S Neptune pin bonds, the usual cross and intertrack bonds being provided.

The overhead equipment is on the span-wire system, a double line of trolley wire being used throughout. The standards are made up of solid-drawn weldless steel tubes, and have an over-all length of 28ft. They are set 6ft. deep below the upper surface of the rails, the excavation being entirely filled with concrete. The trolley wires consist of hard-drawn copper ·364in. diameter, with a breaking strain of 23 tons per square inch. Section insulators are provided, so that each half-mile of trolley can be controlled separately if required. Lightning arresters of the Garton-Daniel type have been provided at every half-mile of route.

The feeder system, which is a somewhat elaborate one for an Eastern tramway, consists of solid soft-drawn copper wire, carried on special high-resistance toggle-clamp insulators, which are in turn bolted to substantial malleable iron brackets attached to the poles. At several points along the route of the tramways these feeders are tapped by

Digitized by Google

insulated cables, which are connected to the main feeder switches in switch pillars fixed on the sidewalk, in a manner similar to what is used in underground feeders.

The rolling-stock consists of 24 electric motorcars of the single-deck, open, cross-bench type. They have all the very latest improvements, and were built for Dick, Kerr, and Co., Limited, by the Electric Railway and Tramway Carriage Works, Limited, Preston. Special care has been taken in designing the cars to ensure the interchangeability of all the important parts entering into the construction of the rolling-stock; the car bodies are 35ft. 4½in. in length, and about 6ft. wide, and are designed to provide seating accommodation for 48 passengers. The floor frames are built of well-seasoned teak in combination with steel sections of such members and sizes as to ensure maximum strength and minimum weight. Openings are arranged in the frame over the motors to afford convenient access to the armature brushes and to all bearings requiring frequent inspection and oiling. The platform floor frames are formed of teak timbers, extending under the main floor frame as far as possible without interfering with the clearance of the trucks, and project out from each end sill 3ft. to provide room for the brake shaft and controllers. Teak end bars are secured to the outside ends of these timbers, forming sills, to which the platform dashes and the entrance steps are secured. The main floor is laid with ⅞in. matched teak boards, and secured at all bearings with barbed wire nails. To prevent the car from sagging, a substantial truss is provided, supported in the centre by two wrought-iron standards. The roof frames are composed entirely of teak, the covering being of cotton duck, laid wet in a coat of white lead paint. Storm curtains are provided for each side entrance of the cars, sliding in grooves between the post. The dashes are made up of No. 16 B.W.G. steel plates, furnished with substantial iron rails and wrought-iron post. The collision buffers are made up of 3ft. by 5in. steel angles, and are secured to the ends of the platform to protect them from injury in case of accidents. These are slotted, and pins provided to enable hauling of cars in case of emergency. Each car is provided with two circuits of 100-volt incandescent lamps, with change-over switches for putting one or the other headlight in circuit.

The trucks upon which the cars are mounted are of the Brush Company's single type; they are suitably built to support the car bodies and to receive the motors and gearing. The cars are fitted with a complete set of electrical equipments, each set consisting of two of the well-known Dick-Kerr standard 25B traction motors, capable of delivering approximately 28 h.p., the temperature of the various parts not exceeding 75deg. C. after running at full load for one hour. The controllers supplied with the electrical equipments are of the same firm's standard D B 1 form, C type, especially arranged with resistances for emergency braking, operated by the driving handle, which may be utilised either when the car is proceeding forwards or backwards. The power-house has been erected on the company's site in Seventy-Eighth-street, together with the necessary offices, car-shed, and repair shops. The steam plant consists of three Babcock and Wilcox water-tube boilers, with a working pressure of 160lb. per square inch; each boiler is provided with a steam superheater fitted with all the usual accessories, a water storage tank with a capacity of 20,000 gallons of water, a fuel economiser, and two double-acting single-cylinder feed pumps, each capable of delivering 2,000 gallons of water per hour.

The engines, which are three in number, are of the well-known Belliss compound two-crank type, mounted on bed-plates extended to take the direct-coupled generators. Each engine is fitted with a heavy flywheel and steam separator, and is capable of giving a normal output of 300 b.h p. when running at 400 revolutions per minute, non-condensing, with steam at a pressure of 155lb. per square inch at the stop valve.

The electrical plant consists of three continuous-current compound-wound generators, coupled direct to the engines, the output of each generator being 200 kw. when running at 400 revolutions per minute, and they are designed to give an overload of 20 per cent. for 2½ hours, with a moderate rise of temperature, current being developed at a voltage of 500-550. The generators are in every respect in accordance with the standard practice of Dick, Kerr, and Co., Limited, the magnet frames being of cast iron, the pole-pieces being built of laminated steel and cast into the magnet frame. The commutation is sparkless at all loads, and the field windings are so arranged to give a 10 per cent. rise in the E.M F. from no load to full load. The switchboard was built by Dick, Kerr, and Co, Limited, and consists of nine black enamelled slate panels 1½in. thick, each supported independently on an iron frame. The board consists of three generator panels, four feeder panels, one station lighting, one Board of Trade panel. Each generator panel is provided with two single-pole switches, one being on each panel; one equalising switch to connect the shunt of the compound-wound dynamo on to the equalising omnibus bar; one shunt field rheostat to enable the E.M F. of the generator to be raised and lowered 50 volts; one field switch with resistance and pilot lamp; one main ammeter; an automatic circuit breaker with magnetic blow-out. Each feeder panel is provided with one main single-pole switch; one automatic circuit breaker; one ammeter. The testing panel has mounted on it all the necessary instruments and switches for recording or measuring the leakage taking place. Also recording voltmeter for recording the difference in potential between the terminus ends of the rails and the negative omnibus bar. The station circuit panel is mounted with all the necessary switches and fuses, together with ammeters required for the station lighting and motor circuits.

One of Higginbottom and Mannock's 10-ton engine-room travelling cranes for a span of 38½ft., with a lift of 20ft., has been erected in the power-house, the lifting longitudinal and transverse traverse being worked by chains from the engine-room floor.

The contractors for the whole of the work and plant were the well-known firm of Messrs. Dick, Kerr, and Co., Limited, represented in Mandalay by Mr. T. Williamson. The sub-contractors were Messrs. Nahapiet and Martin, of Rangoon. The consulting engineers for the work were Messrs. Kincaid, Waller, Manville, and Dawson, of Westminster, who prepared the detailed plans and specifications, and were represented in Mandalay by Mr. E. Sellon. The local work was carried out under the able superintendence of Mr. Griffin and Mr. A. C. Morgan.

MUNICIPAL TRAMWAYS ASSOCIATION OF GREAT BRITAIN.

LIVERPOOL CONGRESS

Presidential Address.

BY MR. C. R. BELLAMY, A.M.I.C.E.

My first duty, and a very pleasurable one, is to thank the members of this association for the honour conferred in electing me its second president. It is customary, and perhaps convenient, for the president's address to immediately succeed his election. Circumstances over which I had no control rendered it impossible for me to attend the first conference of the enlarged association at Glasgow in July last, to do honour to our first president, Mr. Young. Had I been present, I should have felt inclined to suggest that our good friend should have held the office until the Liverpool meeting, an arrangement which would have imparted to my address to-day the perhaps more fitting and congenial flavour of the inaugural presidential address, rather than the valedictory discourse of one relinquishing a pleasurable and distinguished position.

Recognising the importance of the position to which you were good enough to call me, I have from the outset done my best to maintain and enhance the usefulness and prosperity of the association. Primarily affiliated in membership for the betterment of tramway interests and for the cultivation of the social instinct which, notwithstanding our toilsome lives and incessant worries, survives in very vital force, we are invariably animated by the consciousness that the central objects of our official existence are the public weal and advantage, and there is not among us one who

Digitized by Google

holds or works to any other belief, save the one essential that the interests of managers and the public in municipal tramways are mutual, and act and react one upon another. Efficiency, always with due regard to economy, in tramways management is the indispensable handmaid to public convenience. Acutely mindful of this, the ideal which our association inculcates in its members is just that efficiency of administration and service which accounts for the greatest public benefit in the realm of street travel.

May I be permitted, as its mouthpiece for the moment, to claim for the association the extension to members of municipalities as well as managers such ever ready help and direction as cannot be secured through any other channel. With interests so obviously mutual you will, I am sure, be prepared to agree that any subject or scheme paraded for consideration should appeal with equal force to the civic representative as well as the manager. Hence it is needless for me to apologise for bringing before you now, not as the critic, and certainly not as the dogmatist, but necessarily in a more or less cursory way, though with a very earnest purpose, one or two of the topics affecting tramway interests, wide and general in their scope, which may form reasonable matter for careful thought.

As a preliminary, it is perhaps well that I should refer to the progress and work of the association during the year. Since the Glasgow conference 11 corporations and 13 officials have been added to the roll, the association now numbering 56 corporations and 71 managers or their assistants. This indicates that practically all the municipal tramway undertakings of the country are allied with us, a circumstance upon which we are reasonably entitled to congratulate ourselves. The standardisation of tramway accounts, which was referred at the last conference to a joint committee of the Institute of Municipal Treasurers and Accountants and this association, has been pushed forward with the vigour and care which the importance of the subject demanded. As a result of conferences held at Nottingham and Bradford, a form of accounts has been evolved which it is hoped will meet the requirement of enabling a fair comparison to be made of the working results of comparable undertakings. The initial difficulty appeared to be to bring into line for the purpose those undertakings which generate their own electricity with those purchasing from another source, chiefly owing to the impossibility of dealing with capital charges in the revenue account. The trouble has been overcome by providing a supplementary statement setting forth the total energy costs in the case of self-contained undertakings, which will be comparable with the purchase price of the others. The vexed question of differential depreciation has been left entirely open by carrying the balance from net revenue account to an appropriation account, where, after satisfying mortgage loans and sinking fund charges, any balance is allocated either to "reserve or renewal fund," or to "relief of rates." Mr. Dalrymple, who introduced the subject of standardisation at our last conference, will at a later stage to-day give you a more detailed description of the form now submitted for final approval, which will doubtless be most interesting and useful.

In May last the managers' section of the association had a meeting at Bradford, where we were met by the mayor, and entertained most hospitably by the Tramways Committee. The conference was of the nature of a family gathering, where there was no "chiel amang no takin' notes," and we discussed our failures freely, as well as our successes, and exchanged experiences on a variety of topics of everyday interest, with great advantage to all.

The municipalisation of British tramways is making steady progress, about 215 additional miles of tramways having been applied for during the present session under an estimated cost of over £5,000,000, and provisional orders have been granted for about 34 miles, the estimated expenditure amounting to £307,380. There is evidence of a better recognition of the principle underlying the early action of some of the large towns in arranging to acquire or operate the tramways of small adjacent authorities. It is increasingly clear that unity means strength and makes for success in tramway operations, and that what could not be obtained in small self-contained concerns is readily secured under a combination extending the obvious advantages of a large undertaking over the whole of the area administered. In this connection the subject of through running becomes increasingly important, because where combination or absorption cannot be arranged between adjoining districts, it will have to be considered. The convenience of the public must always be placed in the forefront of traffic considerations, and just as the railway companies had to arrange through running very early in their history, so it is becoming a necessity with the ever-extending systems of tramways, and it is desirable that this should be recognised, and the principles controlling it settled by municipalities while their position for purposes of negotiation is strong. In many cases where adjacent local authorities have failed to amalgamate for tramway purposes or link their systems, company promoters, recognising the necessity, have stepped in to provide the required connections. Thus, in the case of our own county, the South Lancashire Company has connected or obtained authority for connecting 28 of the principal towns, bringing into one vast network Liverpool and Manchester, which in turn is rapidly linking itself with an equally important combination of the principal towns of Yorkshire. It is unfortunate that the municipalities concerned do not control all these lines. Under a system of joint municipal ownership and more centralised management their usefulness would be enormously increased. There are many important reasons why the work of tramways should be largely extended. There are considerations apart and beyond the immediate benefits to the public that would follow.

The safeguarding of the financial stability of our undertakings must be considered. It must have struck the student of municipal tramway administration throughout the country that there is a tendency under periodic pressure to make unsound concessions. The returns for last year disclose the grave fact that nearly a dozen municipal undertakings ended the year with a deficit. It is probable that in most of these cases satisfactory results would have been obtained if routes, stages, and fares had been arranged on a basis suitable to the particular district concerned, rather than framed in an attempt to imitate those of large towns, where continuous streams of point-to-point traffic alone render them possible. In the large towns there are also signs of danger ahead.

Great benefits have accrued under municipal control. Routes, service, and speed of cars have been largely increased, with a reduction in many cases to less than one-half the fares under horse traction. A few years ago a house in the suburbs was regarded as in an eligible position if it were within 10 or 12 minutes' walk of a railway station, with a quarter or half-hourly service. To-day the tramways are within a few minutes' walk of everyone's door, with a practically continuous service at all times of the day, and nearly all night, throughout the year, and prudence suggests that further concessions should be sparingly accorded until systems are consolidated and their financial stability finally secured. It is, however, difficult to obtain proper recognition of these requirements, and we all experience the well-nigh impossible task of resisting at certain periods of the year proposals which are fraught with grave danger. The halfpenny stage, the penny universal fare, the all-night service, the season ticket, a multiplication of adjacent parallel routes, and lately farthing fares for scholars, are all questions of most serious importance, which, if carelessly dealt with, may at any time lead to disastrous results, and the obvious danger underlying them should suggest the advisability of increasing the sources of tramway revenue in directions less subject to popular attack.

It will be remembered that the Tramways Act of 1870 provided for a general merchandise traffic, and while this class of business under company control has been practically ignored, it is probable that with interurban connections and joint municipal control it would become a very useful source of additional revenue as well as a great boon to important sections of the trade of the country. It is satisfactory to note that the carriage of parcels has already been taken up on nearly one-half of our tramway systems. For many years it has been apparent that some better method of collecting and carrying the agricultural and

Digitized by Google

varied produce of the districts surrounding large towns has been necessary beyond that provided by the railways, which cater almost exclusively for the traffic between the large centres. Considerable areas are wholly without any form of carriage other than the horse vehicles—in fact, the abandonment of the canals of the country, largely as a result of their purchase by the railway companies, has reduced the distributing network. This was made clear in the evidence tendered to the Royal Commission on Agricultural Depression in 1895 to 1897, when the Light Railway Act was offered as a possible solution of the difficulty. Under this Act the Treasury was empowered to make loans for the construction of light railways and free grants where the construction of such railways would benefit agriculture or connect fishing harbours with a market, or for the development or maintenance of some definite industry. During the first seven years of the operation of this Act 257 applications were sent to the Board of Trade for confirmation, the length of line being 1,638 miles, and the estimated cost £12,150,447; but these were largely for passenger tramways, which I do not think were contemplated under the Act, and, therefore, towards the construction of these lines the Treasury has only assisted to the extent of £250,000 by loan or free grant. The object of the Government in passing the Light Railway Act was avowedly in the interest of the small agriculturists and traders carrying on business at distances from the railway which excluded them from the markets of the country.

The recommendations of the committee on which the Bill was framed were mainly on two points—the cheapening of the methods of obtaining parliamentary powers, and the relaxation of the Board of Trade requirements. The Bill proposed to commit the authorisation of light railways to county councils and county boroughs. The committee reported that they had given special attention to the case of light railways in agricultural districts, and had also considered tramways in rural as well as urban districts, and pointed out that the powers then existing had not been availed of in the case of light railways owing to the consent of the railway companies being necessary, and to want of latitude on the part of the Board of Trade, and, in the case of tramways, in consequence of the local authorities requiring conditions which were considered too onerous.

The committee considered that impediments to construction might be greatly diminished, and that on a large portion of the lines contemplated regulations which had been previously enforced might be considerably relaxed. It was considered that the newly-formed county councils and county boroughs might be vested with powers of authorisation, which it was assumed would be exercised with due regard to the existence of local control and responsibility. With these changes it was thought that the initial cost of construction and the expense of working would be so greatly reduced that many light railways and tramways would be constructed to the general advantage of trade, and especially to agricultural districts without any satisfactory means of transport.

The Light Railways Act has failed for two principal reasons: firstly, because the authorisation was not transferred to local authorities; and, secondly, largely consequent upon the first, local authorities have not attempted to provide the railways. Market gardening, including fruit-growing and dairy work, are carried on profitably within easy cartage distance of any large town, but beyond a radius of a few miles from such centres heavy cartage and railway terminal charges, coupled with the unavoidably delay attending transhipment in transit, render these industries unremunerative. Declining agriculture has led many of our legislators to consider the problem of dealing with the production in this country of fruit, vegetables, and dairy produce which our climate favours, and which is at present largely imported. Their production at home would take a large amount of labour back to the land, which for present bulk crops is principally operated by machinery. The imports of food stuffs capable of being raised at home amounted in 1903 to the amazing total of £43,752,162, made up as follows—viz.: butter, £20,798,707; cheese, £7,054,710; eggs, £6,617,599; apples, £2,781,643; cherries, £167,142; gooseberries, £28,444; grapes, £715,057; pears, £326,463; plums, £622,268; strawberries, £49,362; honey, £30,349; milk (fresh), £1,062; onions, £1,003,016; potatoes, £2,603,238; tomatoes, £953,102. Competent authorities have persistently asserted that the bulk of this produce could be profitably raised in this country if it were possible to convey it cheaply and expeditiously from the producer to the consumer.

The only attempted solution of this problem was the effort to promote the construction of light railways, which, by reason of their cheaper construction, would, it was hoped, provide a network of mechanical carriage of great flexibility capable of dealing with a traffic that the railways do not, and cannot, cater for. An American has said in describing a tramway goods system that it was as flexible as an elephant's trunk, and quite as capable of picking up small things, and that it could flourish on the crumbs that a steam railway would despise. It is this power to pick up small things over large areas expeditiously, cheaply, and frequently which the railway companies lack, and for which they should welcome us as allies. The ever-increasing network of municipal tramways, with their connecting links, might quickly provide the whole country with a system cheaper in operation than was contemplated under the Light Railways Act, which would do much under proper recognition of its capacity to largely increase the trade and revenue of the country. There can be no doubt as to this in the minds of anyone who has had an opportunity of seeing what has been effected in America in connection with interurban tramways. The manufacturer there has no difficulty in selecting a cheap and suitable site for building, as an inexpensive tramway siding to his premises connects him practically at any point with the gathering and distributing systems of the country. Agriculturists are largely benefited, cheap and rapid transit between the land and the town for more remunerative produce is secured, and where large systems such as Detroit, Cleveland, Toledo, and Buffalo have got well under weigh, it is clear that large and general benefits ensue, and no interests are adversely affected.

It was at one time thought that goods traffic on tramways would interfere very largely with the revenue of railways, but it is found that tramways make a business peculiarly their own, while aiding largely in the development of railways. In the towns referred to, industrial life appears to follow the interurban tramways, and the land has been put to far more profitable use. Beet sugar factories have been erected in positions which would have been quite impossible but for the tramways, which ramify into the district, collect the beet and convey it to the factory, and take the manufactured article from the factory to the steam railways with which they are connected. Fruit-growing over a largely widened area is becoming highly remunerative. Suitably arranged cars are run into the heart of the country at various points, where the freshly-gathered fruit is collected and carried on trays on adjustable shelves right into the town markets, where it is on sale within two or three hours of gathering from a distance of 20 to 30 miles. In these towns the rail and tramway companies are working with the utmost harmony, their systems are connected, and often a number of railway cars are taken from the steam roads over the tramways by electric locomotives from point to point in the city to the great advantage of traders, who, by this means, secure much earlier and cheaper delivery. I believe there is great scope for such a development of tramways in this country. With the provision of such a system a farmer would be able to place his produce on a car always within easy cartage distance of his land, with a certainty that it would be promptly delivered into the market of one of the adjacent towns, whither he could accompany it for a few pence. Traders and manufacturers could obtain or send light consignments of goods at any time under short notice to the connected towns, railways, or docks. They could replenish their supplies from the markets or cold stores by telephonic order practically in a few minutes, and the experience of America that such traffic on tramways assists rather than injures railway companies would be demonstrated in this country.

Coming nearer home, the Belgian light railways may be referred to. These lines are independent of the main lines, but in connection with them, and are light rural railways running alongside or on main roads. Generally

Digitized by Google

they are from two to thirty miles in length in the neighbourhood of most of the principal towns. About a quarter of the capital is furnished by the State, another quarter by the provinces, and the remainder by the National Light Railways Society, which is nominally a private company, but is practically controlled by the Belgian Government. Agricultural, dairy, and general produce is carried at very low rates, milk is taken for distribution free of charge, and empties are returned free. It is stated that these railways have been a great success, and the maximum interest of 4½ per cent. paid. A similar system is in operation in Italy and other parts on the Continent; indeed, every country in Europe, with the exception of England, is doing all it can to develop light railways for the benefit of the vast areas of land untouched by railways.

I may refer to a letter sent some time ago by the Belgian Minister of Agriculture to the local government of the various provinces of the kingdom enclosing a circular issued by the National Light Railways Society. It contained the following statement—viz.: "I beg to direct your special attention to the exceptional importance of the work that the National Society is charged to conduct to a successful end, and to the great services which it can render to the country. The society comes at the precise moment in the middle of the serious crisis which weighs upon agriculture, industry, and commerce—in a word, on all the sources of the prosperity and wealth of the nation. It will be able to contribute largely to diminish the intensity of the crisis, if it is well understood, and wisely made use of. The Government will do everything in its power to encourage the construction of these new methods of communication. For years past the spirit of enterprise and progress has directed itself almost exclusively to the extension and improvement of main lines of railway. It is true that the number of roads and canals has been increased, and that their construction has been improved, but there have been no changes, or almost none, in the manner in which traffic is conducted on these lines of communication. Old-fashioned wagons continue to travel on the high roads, and whereas the price of carriage for long distances has enormously decreased, it costs as much, if not more than it did half a century back to cart a load of wheat. It is the function of light railways to improve this state of things. Constructed, as a general rule, on the existing roads, and, in consequence, more economically than main railway lines, operated with utmost economy, and by means of cheap rolling-stock, they will furnish the people with the means of transporting their products at the lowest possible price. By means of their junctions with the main railway lines, they will render access to them more convenient both for passengers and for goods. They will assist communication from village to village, and from the village to the adjacent station. They will call into being new industries and increase the prosperity of existing industries by affording them new outlets for their products. Finally, they will enable the farmer to procure at a cheap rate the fertilisers necessary to enable him to face foreign competition, and by the low cost of carriage will open to him the markets of his own country as well as those abroad. For many places, deprived, as it seemed, for all time of railway communication, these light railways will furnish an opportunity unhoped for, and possibly the last, of escaping from their fatal position of isolation."

Again, the German Minister of Public Works, on moving the third reading of the Light Railways Law in the German Parliament, stated: "Elsewhere the construction and working of similar light railways have proved a blessing to the country. A traveller to-day through North Italy, through Belgium, and through Holland, can satisfy himself what a blessing these light railways have been. It is as though irrigation canals had been carried through the fields, and everything was growing and flourishing under their fertilising streams. In North Italy, in particular, the blessing which they bring with them is so obvious that even the casual tourist can hardly fail to notice it." Mr. George Lambert, member of the Royal Commission on Agriculture, stated: "The killing competition that now exists in such produce as cereals forces farmers to rely on products of a more perishable, therefore of a less competitive, character. To get these products quickly to the consumer, rapid, cheap, and easy transit is essential, which it would be an enormous benefit to secure."

The municipalities, acting in concert with county councils, have an opportunity of providing a system of light railways by making the most effective use of the public highways, which would render it possible, in addition to other obvious benefits, to produce in our own country the £40,000,000 worth of foodstuffs annually which are at present imported, and would thus confer both upon producer and consumer immeasurable benefits, which should secure to our tramway undertakings the success which has followed the adoption of this class of haulage on the Continent, where, by the cheap concentration of produce and combined bulk forwarding, it has been placed on the English markets under lower transit cost than can be secured by the British farmers operating within 20 or 30 miles of the same market. After studying the evidence given before the Royal Commission on Agricultural Depression, I feel satisfied that farmers and landowners would join with the county council in affording, as far as possible, necessary facilities for the widening of roads, and the provision of common collecting and distributing depôts which might be found necessary.

I would suggest that this association might effectively demonstrate its general usefulness by preparing a memorandum of a scheme for facilitating the provision of interf urban tramways, in conference with the representatives o county councils, for consideration by the Minister of Agriculture. It is not too much to hope that the Government might be induced to accept the recommendations of the Special Committee of 1895 on Light Railways in connection with the amendment of that Act, which is now under consideration, which unfortunately were largely omitted in the present Act, and following the Continental practice of more generous assistance, preferably in the matter of road widening, enabling municipal and county councils acting in concert to provide a system of road carriage which would confer inestimable benefits on the whole community.

Cars: Their Equipment and Maintenance.

BY MR. JOHN ALDWORTH, GENERAL MANAGER, NOTTINGHAM CORPORATION TRAMWAYS.

"Cars: their equipment and maintenance," is undoubtedly one of the most important matters with which tramway managers and their staffs have to deal, as this is the actual and visible source from which the revenue of the undertaking is derived. The average passenger does not trouble himself about such matters as the design or equipment of the power station, and provided there is always sufficient power to run the car on which he is travelling, rests satisfied that everything there is as it should be; but let the car be not quite to his liking as regards accommodation, especially when asked to close up and make room for "just one more, please," or the temperature inside does not exactly suit his particular ideas on the subject, he is often very much in evidence; whilst, for want of something else to grumble at, he occasionally enlarges upon the way in which he would build and run cars if he had anything to do with the matter beyond, as he is fond of telling the tramway employés, "having to help to pay for them."

The subject is also a very large one, and no attempt will be made in this paper to treat it at all fully, as to do so would be to raise more points than could be reasonably dealt with in a paper of this description, or discussed in the limited time at our disposal. The writer, therefore, proposes to touch only upon a few of what he considers to be the most important features, and wishes it to be understood that his observations are chiefly a description of the methods in operation on the Nottingham system, the result of some 11 years' experience in the working of that and other electric tramway undertakings; also that it is not intended to lay down rules and regulations upon matters which have to be dealt with in accordance with the local or special conditions pertaining to each separate undertaking, but only to provide a basis for discussion and comparison with the methods in operation on such undertakings.

Digitized by Google

Design of Cars.—Cars should be of a design and size most suitable for the safe and expeditious handling of the particular class of traffic to be dealt with. For the traffic in the streets of large towns single-truck cars carrying from 50 to 56 passengers are, in the writer's opinion, the most suitable. From the passenger's point of view it gives a more frequent and a quicker service, whilst from an operating point the car is more easily handled, and can work its way through the ordinary traffic of the streets with much less risk of accidents. For dealing with a long-distance and varying traffic over suburban lines, the large bogie car carrying from 80 to 100 passengers has its advantages. Of the reversed and the ordinary type of staircase, both have their advocates. For ensuring the safety of passengers, protecting motormen and conductors from the vagaries of the English climate, and utilising all the space possible for seating accommodation, the reversed type is undoubtedly the best, the chief drawback being that it to some extent obstructs the motorman's view of the traffic on one side; the writer has overcome this difficulty by inserting a small sheet of ¼in. plate glass in the riser of the staircase level with the motorman's head. This device has now been in use for a considerable time, and has proved very effective. The efficient ventilation of the car is one of the things that until quite recently has not had sufficient attention devoted to it, and many of the earlier cars leave much to be desired in this respect. To remedy this defect as much as possible, the writer has had the four corner side ventilating windows, which were originally hinged at the bottom, pivoted vertically at the centre, so that the end of the ventilator nearest the platform swings outward, and the other end inward, thus giving two openings on each side of the car, through which a supply of fresh air is admitted at the front, above the passengers' heads, the foul air being forced out through the two corresponding openings at the rear end. The size of the openings can be regulated according to the state of the weather. With cars having rheostats fixed inside under the seats the question of ventilation becomes still more important, and for this reason, if no other, the writer considers all rheostats should be fixed in some outside position. A folding step is being given a trial in some towns. The writer, however, is unable to give particulars of this device, but hopes something will be said on this subject by the members present who have been trying it. The writer does not propose to touch upon such controversial subjects as top deck covers, dry seats, wind shields, route indicators, and lifeguards, which for some time past have been so much in evidence.

Motors.—To ensure a satisfactory service, it is necessary that cars should be equipped with motors designed to meet the varying conditions of the particular system they have to operate, and be capable of developing sufficient power to enable them to climb the steepest gradient thereon without being unduly overloaded, as, although the initial cost may be lower and the average consumption of current per mile kept a fraction less, with a smaller motor, the additional cost of repairs will more than counterbalance this, to say nothing of the extra risk of breakdowns on the road, with its consequent interruption of traffic. Given a properly designed and sufficiently powerful motor, the important thing is to see that it is well taken care of. This can only be done by having it systematically inspected, and maintained in its most efficient condition. The writer has tried several methods of inspection and reporting upon the condition of the car motors, also of carrying out the repairs, and the following system has been adopted as a result thereof. The commutators, brushes, and brush springs are examined nightly, and where any commutator shows signs of undue sparking or heating, it is carefully examined by the night foreman, and if no cause for it can be discovered, it is cleaned and the car again put into service; instructions are given to the chief motor inspector to test the car on the road during the following day, and if then found to be working unsatisfactory in any way, it is sent into the works to be thoroughly tested and the defect put right. Armature and motor bearings, with their lubricating boxes, are also examined nightly, and any defect discovered is reported to the night foreman, who in every case uses his discretion whether such can efficiently dealt with by himself, or whether the car shall be kept in for it to be dealt with by the day staff. The writer has tried several kinds of white metal for lining motor and armature bearings, also solid gunmetal armature bushes of different mixtures; the latter, however, are not being renewed, but when worn down are bored out and run up with white metal, instead of being scrapped. This has been found to answer well, besides effecting the following saving in the cost of renewals under this head: gunmetal bushes for one armature, including boring and turning, after allowing for their scrap value, 18s. 1¼d.; boring out old bushes, filling with white metal, and boring, 5s. 8d.; each subsequent relining and boring, 1s. 8d, or a difference of 16s. 5¼d. in favour of white metal lining. The average life of the gunmetal bushes has been 25,086 miles, and that of the lined bushes practically the same. A further advantage is found in the fact that, should a bearing run hot, there is not the same danger of the shaft being scored with white metal as is the case with gunmetal. A metal is now being tried for lining, composed of three parts virgin spelter to one part block tin, which is considerably harder than any other white metal tried. This has not been in use sufficiently long to enable particulars to be given of the mileage to be obtained from bearings so lined; but so far they have given good results, the journals being in excellent condition, and the writer has no hesitation in saying they will give a considerably increased mileage. Armatures, field coils, and leads are thoroughly examined, tested, and coated with insulating compound, also commutators turned up, if required, every time the car passes through the repair shops for overhauling the bearings. The writer believes that considerable advantage would result from having commutators ground true instead of being turned up in the lathe, and is now experimenting in this direction. The condition of the armature bearings of each car is determined at least once a month by the night foreman, who tests the clearance between the armature and bottom fields, for which purpose he is provided with a set of steel feelers, numbered, and varying in thickness from $\frac{3}{16}$in. to $\frac{1}{32}$in. The exact clearance of each armature is recorded and sent to the works superintendent, who decides when it is necessary for the bearings of a car to be renewed. After being repaired, each armature undergoes an insulation test, and before being put under a car it is also tested at full load by being run for a period of 15 minutes in either direction. This shows up any defects in the repairs, and ensures it being in perfect working order when again put into service.

Controllers.—Controllers are all examined at the end of each day's work; all contacts are cleaned and thinly coated with vaseline, also adjusted or renewed as found necessary. The whole of the inside is kept perfectly clean, and the parts which require it are periodically coated with insulating compound, with the result that it is a very rare thing for a controller to give trouble.

Automatic Cut-outs.—These appliances from time to time gave considerable trouble on the road, and it was found advisable to calibrate them every time a car passed through the shops for overhauling. This has effectively dealt with that particular trouble.

Trolleys. — All trolleys are examined daily, whilst the poles are also tested for tension, and adjusted (if found necessary) once a month. Experiments have been made with several kinds of trolley-wheel bushes, and one composed of solid graphite has been found to give the best results. The bush, wheel, and spindle, now submitted for your inspection, has run 5,762 car miles, and, although the wheel is nearly worn out, the bush and spindle are very little the worse. They can be put into, and will last the life of, a second wheel. The cost of the bush is 1s. 2d., compared with 1s. paid for the metal-cased graphite bush, of which two are required during the life of one wheel. The protection of passengers from electric shock is an important matter, and to ensure this as far as possible by the immediate detection of a leakage, ruby lamps are being used in the leakage circuit, so that they shall not be confused with the platform lamps. All leakage lamps and circuits, also lightning arresters, are examined and tested at least once a month. Some undertakings have had their cars fitted with a patent "trolley earth indicator," which consists of a short-circuiting switch, held open by means of a fine-

Digitized by Google

wire fuse. This wire is connected in shunt with the switch, and as the whole apparatus is in circuit between the trolley base and earth, immediately upon the standard getting alive the fuse is melted and allows the switch to close by means of a spring. This connects the standard directly to earth, and causes an electric or mechanical bell to be set ringing.

Brakes.—The question of brakes is an important one on every undertaking, but where cars have to negotiate gradients of 1 in 11·5, and carry some of the heaviest rushes of holiday traffic over them, as is the case on the Nottingham system, it becomes a very important one indeed, and the writer considers that too much attention cannot be given to assure their being maintained in the highest possible state of efficiency. It is not proposed to discuss the merits or demerits of the various types on the market, but only to emphasise the importance of having motormen properly instructed in the best way to use the brakes at their disposal, and a systematic inspection and overhauling of such brakes by trained and competent men. Money so spent can be considered as a first-class insurance premium against accidents. All the cars under the control of the writer are equipped with either a mechanical or magnetic track brake, in addition to the ordinary ratchet wheel brake, all of which are carefully examined nightly, and the necessary adjustments or renewals executed. In addition to this, all the brakes of every car are examined and tested once a month under the direct supervision of the works superintendent or his chief assistant. A number of the cars are fitted with an automatic adjusting device for keeping the blocks set to the proper distance from the wheels. These are acting very satisfactorily, and effect a saving in labour. During the time the Nottingham electric system has been in operation—nearly four years—there has not been a single case of a car running away, which of itself fully justifies the great care that has always been bestowed upon this part of the equipment.

Wheels and Axles.—As to the vexed question of steel *versus* chilled-iron wheels, sufficient has been heard of this recently to excuse a comparison of their merits being entered upon in this paper. Like many others, the writer has been experimenting with steel-tyred wheels, but considerable difficulty has been caused by the flanges. Possibly this may be attributed to the fact that they have a large number of curves to negotiate. On one route of about three miles there are seven curves of a radius ranging from 45ft. to about 60ft. Very good results have been obtained from chilled wheels, some having run upwards of 45,000 miles, the average life being 34,124 miles, and in only one case has a pair been trued up in the grinding machine. We have a good permanent way, which doubtless accounts to a large extent for our comparative freedom from the troubles connected with broken axles and wheel flanges. For single-truck cars the tendency appears to be in favour of increasing the size of the axles. This is undoubtedly a step in the right direction, as a much larger diameter might be used with advantage, not only for the additional strength, but also to obtain a larger bearing surface. The writer is not in a position to discuss the question of broken axles, having had but one failure in 6¾ million miles run by the cars.

Inspection and Reports.—To avoid as far as possible breakdowns on the road, and for assisting motormen who might be in difficulties, a motor inspector is stationed at a point on the system where all the lines converge. Defects reported to him are dealt with on the road, or the car changed if necessary, and a daily report of all such cases is made by him. He is in direct telephonic communication with each depôt, which enables him to arrange for the changing of cars at the most convenient point. Definite instructions have also been given that under no circumstances shall a car be allowed to remain in service with its brake in the slightest degree defective. In addition to this, every motorman before going off duty enters in the report book at his depôt particulars of any repairs requiring attention, and attaches his signature thereto. These reports are compared with that of the motor inspector, and a return of all repairs executed during the night is handed in to the works superintendent each morning. The running condition of each car is tested periodically by the chief motor inspector, who himself operates it both up and down the heaviest gradient of the route upon which it is running, and the result thereof is also reported to the works superintendent. This has proved a very effective way of detecting faults and having them dealt with on the "stitch in time" principle, as the inspector being trained to look for defects, and able to compare the running of the different cars over the same route, is much better qualified to detect incipient troubles and express an opinion thereon than is the average motorman, whose reports are often misleading and require to be examined with great care. None but brake and trolley renewals and light repairs are executed at the branch depôts, all cars requiring other attention being sent to the works, by which arrangement the work is carried out under the most economical, expeditious, and efficient conditions.

Equipment of Repair Shops.—To deal with the repairs and upkeep in an economical and satisfactory manner, it is necessary that the shops should be equipped with up-to-date labour-saving machinery, testing machinery, and instruments; and for an undertaking operating from 100 to 150 cars using chilled wheels the following has been found adequate: In the fitting shop—a five-ton electric travelling crane, two lines of shafting (each belt-driven by a 10-h.p. motor), 10in. screw-cutting gap lathe, 6in. screw-cutting lathe with universal chucks, vertical wheel-boring machine, wheel-grinding machine, hydraulic press, radial drilling machine, small sensitive drilling machine, universal shaping machine, power hack saw, screwing machine, acme grinder, grindstone, moulding jigs for lining bearings, lifting jacks, and armature bogies, with various small tools as found necessary. In the armature-room—armature stands, wire drums with tension brakes, furnace, formers, taping machine, drying oven, testing machine, and insulation testing set. In the smiths' shop—two forges, anvils, swage blocks, set of levelling blocks, small power hammer, and "Roots" blower driven by independent motor. In the woodworking shop — line of shafting driven by a 5-h.p. motor, circular-saw bench fitted with boring apparatus, band saw, planing machine, mortising machine, and universal trimmer. The buildings should be constructed, and the machinery arranged, so as to avoid undue handling of the car and different parts of the equipment whilst undergoing repairs. Pits should extend the full length of each track, and communicate with each other; also be fitted with hydraulic platforms for removing wheels and axles from under the cars. To obtain the best results, all the shops should be concentrated as far as possible, have plenty of light and ventilation, and be provided with good heating and sanitary arrangements.

Cleaning and Painting.—As the amount of the painting bill undoubtedly depends largely upon the method of cleaning in operation, these two processes should be considered together. The writer is not sure that the cleaning ought not to be under the control of the foreman car painter, instead of the night foreman, being satisfied that considerable economy can be effected in the painting department by paying every attention to the methods of cleaning; besides which, a well-cleaned and smart-looking car is highly appreciated by the passengers, as well as being a credit to the undertaking. He has always had the cars cleaned with oil, and the amount paid in cleaners' wages is somewhat above the average of other undertakings, but as a number of cars have been in service nearly four years, and the outsides required nothing more than touching up and revarnishing, he considers this course is justified. The insides are kept clean with soap and water, and, with the top seats, are revarnished as required; whilst the top decks are given two coats of best oil paint at least once a year, to ensure their being kept watertight.

General.—To enable a check to be kept upon the repairs bill, which by its tendency to increase appears to be always trying to take a more prominent place in tramway matters, also to decide upon the best methods and materials to be used in connection therewith, full and accurate records should be kept of all matters connected with the running, inspection, and repairs of the cars; as only by a careful study of these can the many points coming under consideration be adequately dealt with. In conclusion, the writer wishes to say he is afraid there is very little new or of a

Digitized by Google

substantial nature contained in the paper, but feels that comparisons of the methods of working, and also the operating expenses of different systems, are always interesting, if not conclusive. A manager whose system consists mainly of steep gradients has reason to feel envious of the low cost, to say nothing about the minimised risk of accidents, at which other systems can be operated whose routes are all practically level. Not only is the consumption of current much heavier with steep gradients, but the writer finds the cost of maintenance also increases in practically the same ratio. No conclusions, therefore, should be drawn from such comparisons without taking into consideration the many different conditions under which the undertakings have to be operated.

Overhead Equipment: Notes on its Construction and Maintenance.

BY MR. J. M. McELROY, GENERAL MANAGER, MANCHESTER CORPORATION TRAMWAYS.

The opinion has often been expressed that many modern inventions—of which our electric tramways systems may be considered a type—have to a large extent had the effect of subduing or rendering less active the æsthetic side of our nature and of bringing into greater and increasing prominence the utilitarian side. In the present "hustling" days it is urged that we have neither time nor inclination to appreciate those things which add to the beauty of our cities and towns, and that we appear to be perfectly satisfied with any modern invention, however inartistic, which brings with it anything in the shape of material advantages. The great benefits, therefore, which our tramways have afforded to the community in the shape of cheap and rapid transit have appealed strongly to the utilitarianism which characterises our modern civilisation. Notwithstanding its ornamental scroll work, tastefully painted poles, gilt finials and rosettes, by no stretch of the imagination can the forest of steel poles and the network of wires which we describe as the "overhead equipment" be considered an embellishment of our towns. It represents a condition of things in which utility absolutely predominates, and æsthetic considerations occupy a very minor place. So say the critics. But with all the objections urged against it, we—in the provinces at any rate—have been driven on economic and other grounds to adopt the overhead system as being the only one commercially possible at the present time. It is, therefore, desirable that we should consider and compare notes as to the best and most suitable methods of constructing and maintaining the equipment.

Points to be Observed in Erection.—The four principal points which ought to be observed in the equipment are: (1) its general stability; (2) its adaptability to the safe, reliable, and easy running of the cars; (3) its erection, so as to be the least objectionable from the æsthetic standpoint; (4) its erection, so as to reduce the wear and tear to a minimum. Each of these points requires careful consideration. Opinions differ as to their relative importance, as will be seen by the replies to the list of queries embodied in the report accompanying this paper.

Centre Running v. Side Running Trolleys.—The general types of construction adopted in this country may be divided into two—namely: (1) those adapted for side running trolleys, and (2) those adapted for centre running. Twenty-six towns have adopted the former and nine the latter type, and 10 have adopted both types. A glance at the replies will show that several towns which have adopted side running now express their preference for centre running lines. The reasons in favour of side running as opposed to centre running equipment are that (1) it is neater in appearance; (2) it is less costly to construct; (3) it is safer for passengers on the cars; (4) it is more easily adapted for running round curves and through junctions, etc. The reasons in favour of centre running as opposed to side running equipment are that (1) it is more flexible, and there is less liability of the trolley leaving the wire—in other words, it is more adaptable to the reliable and easy running of the cars; (2) the pressure of the trolley wheel on the wire need not be so great, and in consequence there is less wear and tear.

Centre-Pole Construction.—The principal reason which has led towns to adopt centre-pole construction is, I believe, that it is or can be made more artistic than span-wire construction. Opinions, however, differ widely as to the desirability from a practical standpoint of adopting this form of construction. It is urged that (1) it is not so elastic as span wire, and (2) the poles form an obstruction to the ordinary vehicular traffic. On the point of elasticity there can be no two opinions, but on the question of obstruction 17 towns report that they consider the poles *do* form an obstruction, and nine towns think otherwise, and, in fact, some urge that they tend to regulate the traffic. This question of obstruction is one which local conditions of traffic must largely enter into; also the width of the streets in which the centre poles are erected. In very wide streets, like Oldham-road in Manchester, which is in parts 72ft. between kerb and kerb, we have not found much to complain of in the way of obstruction, but in streets 35ft. to 40ft. wide the obstruction is apparent to those who drive about the streets.

Trolley Wire.—The size of the trolley wire adopted varies from 0 to 0000. It would be interesting to learn the reasons which led to the adoption of the several gauges. Several towns have adopted or experimented with phono-electric wire. It appears to be giving good results, but the replies indicate that it requires more careful handling during erection than copper wire. It is stated, also, that it has a higher resistance than copper wire. Some further information on this point would be interesting.

Automatic Frogs.—With the exception of Glasgow, and, I think, Aberdeen, who use fixed trolley heads and rigid frogs, all of us are interested in the subject of automatic frogs. From the replies it will be seen that experiments have been and are being tried with some amount of success in many towns. Samples of some of the frogs in use will be exhibited.

Lightning Arresters.—The principal lightning arresters in use are the Garton, the Wurtz, and the British Thomson-Houston. No trouble appears to have been experienced by the majority of the towns due to the arresters being burnt out and rendered useless. Cardiff, however, appears to have had difficulty in this direction, and this has been our experience, too, in Manchester.

Automatic Devices for Cutting off Current in Cases of Falling Wires.—The replies to the query as to the adoption of devices for automatically cutting off the current in case of trolley wires falling show that little has been done in this direction, and that nearly all the towns depend solely on the circuit breakers. In Oldham they have adopted a device described as follows: "Insulated guard wire connected to rails through a solenoid which trips the circuit breaker in the feeder pillar. An arrangement on the guard wire at each arm or span wire to make the guard wire alive if the trolley wire drops." In Leeds they have six poles fitted with Hall's patent mechanical ear, but up to the present these have not been operated. In Dundee a bamboo pole and piece of cable is carried on each car to make a "dead earth" in case of emergency. In Nottingham they adopted a patent short-circuiting device, which gave considerable trouble, and had to be discarded.

Anchoring of Section Insulators.—The question as to the best method of anchoring section insulators is one which ought to receive careful consideration. Several towns—Aberdeen, Sunderland, Leicester, Bradford, Preston, and Dundee—do not anchor their section insulators at all They consider it unnecessary. Many towns—principally those with side running systems—anchor vertically by suitable attachments to the bracket arms. Very few of those who anchor horizontally admit that they form a trap for the trolley.

Insulation of the Line.—To maintain the perfect insulation of the trolley line is an important matter. The replies show that several well-known makes of insulating material appear to be chiefly adopted. It is interesting to notice that double insulation is resorted to by all the towns except three. In Manchester we have adopted triple insulation throughout. In Wallasey they are adopting triple on reconstruction work, and in East Ham they adopt triple on

Digitized by Google

the part of the line exposed to fumes from chemical works. Very few towns appear to have experienced any serious trouble owing to the failure of the insulation.

Inspection of Line.—Careful and constant inspection of the line is of paramount importance if we are to satisfactorily maintain the equipment and to prevent accidents. "Nightly," "daily," "weekly," "fortnightly," "monthly" inspections—these are the replies under this head from the various towns.

Standardisation of Various Types of Poles.—The replies to the query indicate almost a consensus of opinion in favour of the standardisation of poles on the lines suggested by the Engineering Standards Committee. In Cardiff, however, they prefer the single-section taper pole much better than the three-section telescope type, and in Glasgow they state that the dimensions of the poles as agreed upon by the Standards Committee do not suit their requirements in every respect. The recommendations of the Standards Committee are appended.

Pressure of Trolley Wheel on Wire.—It is claimed by some of the advocates of centre running trolleys that one of their advantages is that less pressure may be used by the trolley wheels on the wire. In actual practice we find that for side running trolleys the pressure varies from 18lb. to 32lb., and for centre running trolleys from 16lb. to 25lb., although many towns with side running trolleys are running at less pressure than towns with centre running trolleys. The pressure considerably affects the wear and tear of the equipment, and the figures given by the various towns indicate that this is a subject which ought to claim our careful attention.

Ears.—The type of ear adopted and the method of suspension has a most important bearing upon the wear and tear of the equipment. An ear which firmly supports the wire, and yet at the same time possesses no appreciable thickness, is the desideratum. The ordinary type of ear, which is clipped round the wire and soldered, is by no means perfect. No matter how well the ears are tapered, they cause the trolley wheels to "jump" to a greater or lesser extent each time they travel under them. The consequence is that the wire at the trailing ends of the ears soon begins to show signs of wear. It behoves us, therefore, to consider whether this defect can be remedied, and if so, how? Several types of mechanical ears are exhibited, and may prove of interest to members.

Guard Wires.—All guard wires we must assume are fixed and "earthed" so as to comply with the Board of Trade regulations. Some towns, however, "earth" them at less distances than the maximum prescribed by the Board of Trade. In only one town are the earth wires disconnected when linesmen are working on "live" wires.

Section Insulators, etc.—The general type of section insulator adopted is the air-gap. I have requested all our members who have adopted or experimented with any special type of section insulators, frogs, crossings, or other line material to forward me samples for exhibition at the conference.

Wear of Trolley Wire.—The wear of the trolley wire is an important matter, and some reliable data from the various towns would be valuable. In Liverpool we are informed that the life of their 0 wire is about five years. In Glasgow the records show that their 00 wire has a life of three years with a service of 2½ cars per minute. In Dover the reply is: "Portions of the 0 wire taken from curves near depôt had flattened near ears, and that at point of greatest wear, instead of a sectional area of ·082448 square inch there remained only ·054964 square inch after four years and two months with a six minutes' service and constant shunting operations." In Oldham we are told that the wire is wearing flat in the sides at the ends of the ears. In Cardiff, where they use 000 wire, they have found the wear very great in places, and renewals have taken place. In Burnley the experience is: "No appreciable wear in three years except close to section insulators." The Leeds experience is remarkable. Here they use 0000 wire, and on their oldest line, which has been in operation over seven years, and on portions of which there is a maximum service of 1½ minutes, the wear on the wire on straight line is imperceptible. The wear on curves is very slight, and will not necessitate renewal of the wire for a considerable time yet. In Bradford the wear on their 0000 wire is inappreciable. In Blackburn the oldest line is five years. They use a 0 wire, and the wear on straight track is very slight. In Dundee it is stated that up to the present no wear in the trolley wires is noticeable.

Motor Tower Wagons.—The adoption of motor tower wagons in lieu of horse wagons for emergency work is gradually taking place, and they appear to be giving satisfaction. Mr. Hamilton, of Leeds, states the advantages of the motor wagons very tersely as follows: We prefer a motor tower wagon for emergency calls for the following reasons: (1) Can reach scene of breakdown more quickly. This is especially the case on a long run. (2) It deteriorates horses to gallop two or three miles with a load approaching two tons, and then stand for a considerable time whilst the repairs are being executed. (3) There is always the possibility that, no matter how well trained, horses may start suddenly whilst the men are at work on the derrick; in fact, unless carefully watched they are very likely to be restive, as there is nearly always a crowd gathered where a breakdown has occurred.

Span Wire.—The action of the atmosphere on span wires, and the means adopted to prevent it, was inadvertently omitted from my list of queries. We in Manchester are finding that the atmosphere is seriously affecting our span wires, especially in one district, where there are a number of chemical works. We have used vaseline, and also several so-called "rust-preventing" mixtures, but nothing so far has been effective. It would be interesting to have the experience of other towns on this matter.

Working of Trolley Lines Separately.—In operating a tramway system, it is desirable from a traffic point of view that the trolley lines should be worked separately, and this appears to be the general practice. In the large cities, however, the practice appears to be to work in parallel the lines in the busiest routes.

Trolley Wheels.—Fixed trolley heads are in use in Glasgow and, I think, in Aberdeen. All the other towns, I believe, use the swivelling head. The principal objection to the fixed head is that it tends to produce greater wear and tear on the overhead work at curves. On the other hand, it admits of the adoption of rigid frogs, and that is an advantage. The swivelling head has been constructed in a variety of forms. This is one of the parts of tramway equipment upon which inventors have been particularly keen. I should not be at all surprised to learn that no two towns have adopted precisely the same type of trolley head. The samples exhibited show some of the varieties. For the same gauge of wire the grooves vary considerably. The make of trolley wheel and the groove adopted has an important bearing on the life of the wire, and daily attention ought to be given to the examination of the trolley wheels with a view to renewing those which have become worn. This has an important bearing on the life of the overhead equiqment.

Conclusion.—In conclusion, it is needless for me to point out that I have not attempted to deal with all the possible questions which could be raised in connection with the construction and maintenance of the overhead equipment. What I have done is to present to you some of the points which have from time to time presented themselves to me in the construction and maintenance of the Manchester equipment, and I trust they will lead to an interesting and instructive discussion.

British Standard Specification for Tubular Tramway Poles.

1. The poles shall be of mild steel, free of all defects, and shall be of three classes—light pole, medium pole, heavy pole.

2. The sectional poles shall be either solid-drawn or lap-welded wrought steel, free from all defects, made up in three sections, swaged together when hot so as to make a perfect joint. The lap-welded seams in the sections shall be set at an angle of 120deg. to each other. The taper poles shall be of wrought steel, free of all defects, rolled in one length and butt-welded the entire length. The butt-welding shall be carried out at an even temperature without overheating, and no pole shall show any signs of burning at the weld.

Digitized by Google

3. The over-all length of poles of all classes shall be 31ft.

4. The length of the telescope joint in the sectional poles shall be 18in.

5. The length of the sections shall be: top section, 8ft. 6in.; middle section, 8ft. 6in.; bottom section, 17ft.

6. The outside diameters, in inches, of the three classes of both sectional and taper poles shall be

Sectional Poles.

Class.	Top.	Middle.	Bottom
Light	5½in.	6½in.	7½in.
Medium	6½in.	7½in.	8½in.
Heavy	7½in.	8½in.	9½in.

Taper Poles.

Class.	Top.	Outside diameter 9ft. 6in. from base.
Light	4⅜in.	7½in.
Medium	5⅜in.	8½in.
Heavy	6⅜in.	9½in.

7. The thickness of metal in any pole shall not be less than ¼in.

8. The completed poles shall be straight and true over their entire length to within ½in.

9. The section of any pole shall be as nearly circular as possible, not varying in diameter by more than $\frac{1}{16}$in. from the adopted standard.

10. Five per cent. of each class of sectional pole shall be subjected to the following drop test: The pole shall be dropped vertically, butt downwards, three times in succession, from a height of 6ft., on to a hard wood block 6in. thick laid on a concrete foundation, without showing any signs of telescoping or loosening of joints.

11. Five per cent. of each class of both sectional and taper pole shall be subjected to the following bending tests: The pole shall, in each case, be rigidly supported for 6ft. from the butt, and loaded, as a cantilever, 18in. from the top, the load being applied at right angles to the axis of the pole, which shall be fixed horizontally. Upon the application of the following loads in pounds, the temporary deflection and permanent set, measured at the point of application of the load, shall not exceed the figures stated in the tables.

Class of pole.	Load in lbs. for temporary deflection not exceeding 6in.	Load in lbs. for permanent set not exceeding ½in.
Light	750lb.	1,000lb.
Medium	1,250lb.	1,750lb.
Heavy	2,000lb.	2,500lb.

12. In the event of any pole of the above-mentioned 5 per cent. not fulfilling the test requirements, a further 5 per cent. shall be subjected to the tests enumerated above. Should any further failure occur, the whole parcel from which the poles have been selected shall be liable to rejection.

13. The maker, at his own expense, and to the satisfaction of the engineer, shall provide all the necessary testing apparatus at his own works for carrying out the above-mentioned tests.

BRITISH VERSUS FOREIGN JOISTS.

We have had complaints from time to time of the alleged apathy of the British manufacturer, and one of the favourite instances as showing the want of enterprise on the part of the British manufacturer was his inability to supply rolled-steel joists or beams. This trade was in the hands of the Belgians and Germans, and the steel joists or beams, while varying in quality and workmanship according to the maker, were usually of the "cheap and nasty" order.

When English engineers began to impose tests and inspection on Belgian iron joists the "reputation" of Belgian iron joists did not last long, and a year or two of experience with steel joists promptly killed the iron joist trade. To-day Great Britain has a number of steelworks all capable of supplying a full range of sizes of first-class rolled-steel beams. The complaint urged by engineers that in specifying English joists or beams they never knew the properties of the section, and were likely to be in the hands of one maker only, from whom delivery might be difficult to obtain, has disappeared.

Thanks to the laying down of properties of sections for British standard beams by the Engineering Standards Committee, it is now possible to get joists or beams from several works simultaneously, which enables stocks to be kept and prompt deliveries obtained from any girder merchant or manufacturer. But the British steelmakers, having given proofs of their enterprise in laying down mills and plant for the production of rolled-steel beams, may fairly ask the engineer and architect to encourage this enterprise by using the beam or joist shape freely in their designs, and by stipulating in their specifications that beams shall be of British manufacture. Something of this kind is necessary for two or three reasons.

First and foremost, the quality of British rolled-steel beams is always superior to that of any foreign make; secondly, the sections of British standard beams will carry a higher load per pound of metal employed than any beam of similar size of foreign make; thirdly, British steel beams are made by the Siemens-Martin open-hearth (acid) process, which is to to be preferred for all steel shapes where the best quality is wanted. Some steelmakers employ the Siemens-Martin (basic) process. Engineers, therefore, can indulge their fancy for steel made by the Siemens-Martin open-hearth process, leaving it to the individual maker to supply Siemens (acid) steel or Siemens (basic) steel.

At the present time there are not sufficient orders for rolled-steel beams to fully occupy one works, let alone all the various works who have suitable plant. It is certain that there is so much competition amongst British steelmakers, that no user to-day would be inconvenienced by having to wait for delivery or would fail to get low prices. The more British engineers stipulate for British steel beams to be used in their structures, the sooner will the steelmakers find out means of reducing their cost. To-day, however, the British engineer can include British beams in his designs with the certainty that they will be furnished at lower cost than is involved to the American engineer who confines himself to American steel beams; or to the German engineer who confines himself to German steel beams.

As a matter of fact, foreign engineers help their own countrymen in matters of this kind to a greater extent than is found in this country. Unless engineers specify for British material, there are always to be found second-rate producers of constructional ironwork, who will put in any foreign material if they can only gain a little more money than would be the case by using safe and reputable British steel. The ordinary builder, unless he is controlled, presses the girder merchant to supply him with something cheap, and the girder merchant buys and stocks, with a few rare exceptions, the cheapest material he can find.

The lists which are usually circulated showing the carrying capacities of foreign-made beams or joists are usually untrustworthy, and do not seem to be based upon safe practice or trustworthy working stresses. Where a man has a cheap job to do and wants English sizes and foreign material, it would be only prudent on his part to stipulate that the web and flange thicknesses and other properties of the section should be those of British standard beams. Furthermore, it should always be insisted upon that the steel shall be equal to a tensile breaking stress of from 28 to 32 tons per square inch, with an elongation after fracture of not less than 20 per cent. on original datum points, 8in. apart. If these things are insisted upon, a standard of quality and workmanship will be kept up, which is at present being lowered to the detriment of all those who like to see sound and good work.

THE MAGNETIC RESISTANCE OF AIR-GAPS.*

It is difficult in certain calculations to obtain even approximately correct results, owing to the unknown amount of the spreading of the magnetic lines passing between two pole-faces. The author has, therefore, had a series of experiments made on the simplest case of this

*Translation of an article by G. Benischke in *Elektrotechnische Zeitschrift*, Sept. 15, 1904.

Digitized by Google

nature—viz, a flux passing between two parallel square pole-pieces with the exciting coils wound close up to the pole-faces (Fig 1). The faces of the coils were actually about 1cm. from the pole-faces, and the iron core was from 2mm. to 5mm. from the winding surrounding it.

Alternating current was employed for the measurements, as the determination of the flux is simpler with this than with direct-current excitation. The core was made up of

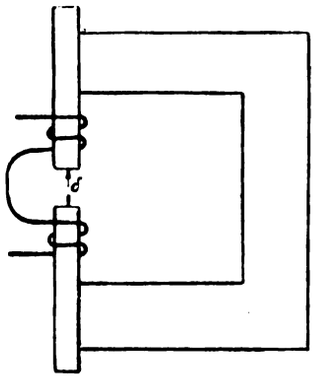


FIG. 1.

·5mm. iron laminations. The magnetic resistance, w_g, of the path is obtainable from the two following equations:

$$Z = \frac{E \times 10^8}{4{\cdot}44\, n\, N} \text{ and } Z = \frac{{\cdot}4 \times \pi \times I_m \times N}{w_g}$$

Z being the total flux, I_m the maximum instantaneous value of the magnetising current, N the number of turns, and n the frequency. The E.M.F. and the $\sqrt{M S}$ value, J_m, of the magnetising current are obtained by measurements of the terminal voltage, the watts absorbed, and the current. I_m is then obtained by multiplying J_m by the form factor of the current wave, which, in the case of a choking coil with unsaturated iron (B about 5,000) and comparatively large air-gap, is very nearly the same as the form factor of the E M F. wave. As the latter was sinusoidal, the form factor has been taken as 1·4

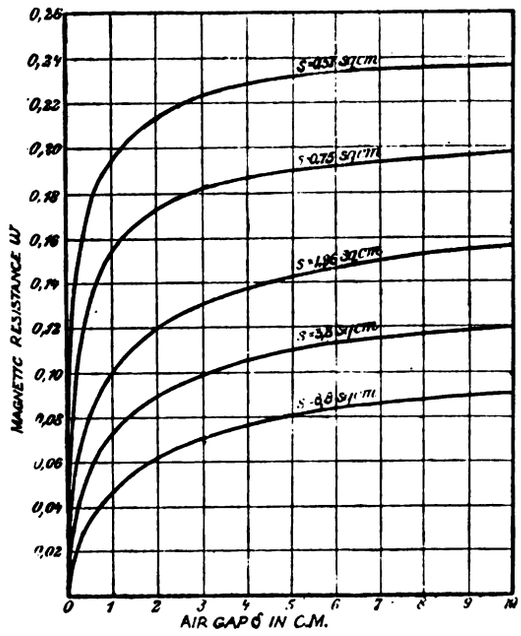

FIG 2.

The magnetic resistance of the iron path was in all cases subtracted from the total resistance, w_g, and in this way the curves of air-gap resistance, w, shown in Fig. 2 were obtained for pole-faces of the areas s = ·37, ·75, 1 96, 3·8, and 8·8 square centimetres respectively with different lengths of air-gap, δ. From these curves the equivalent air-gap area, S—*i.e.*, the area which the magnetic path would have if the lines were parallel and of uniform density—can be calulated from the formula $w = \frac{\delta}{S}$.

This has been done, and the result is shown in Fig. 3. It will be seen that these curves are approximately straight lines of the form $S = s + K\,\delta$, where s is the height at which the line cuts the ordinate axis for $\delta = 0$—*i.e.*, it is the actual section of the pole-face. The factor K, which is the tangent of the lines, is different for different pole-face areas.

The different values of K in relation to the pole-face are:

s	·37	...	·75	...	1 96	...	3·8	...	8·8
K	4·3	...	5·2	...	7·2	...	9 2	..	11·8

and these values are plotted in Fig. 4.

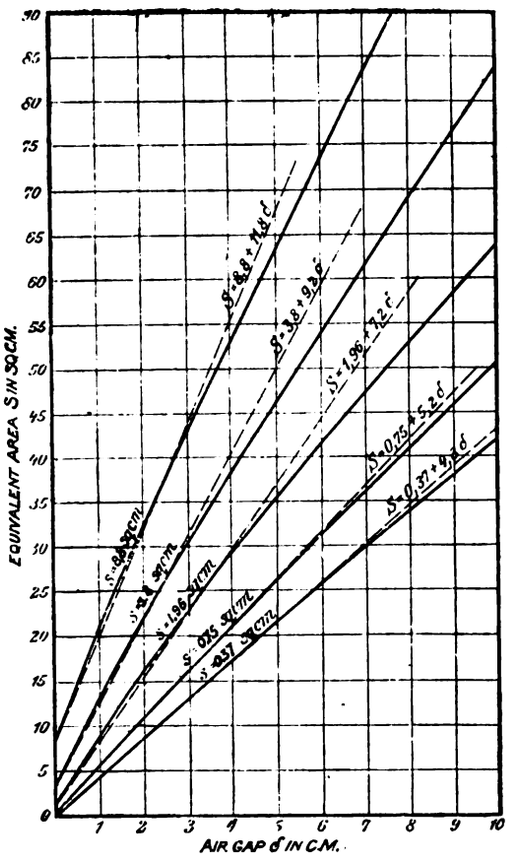

FIG. 3.

By means of these curves and the above equation it is possible to calculate the equivalent air gap area, S, up to an air-gap length of 8cm. in the case of the smallest pole-piece, and 4cm. in the case of the largest pole-piece, with fair accuracy.

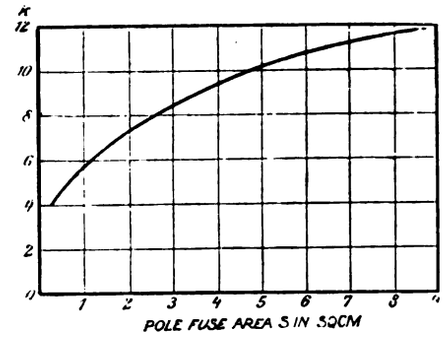

FIG. 4.

For greater air-gap lengths it would be necessary either to work out fresh values for the equation by means of Fig. 3, or to obtain the required value of the resistance by interpolation or extrapolation from the curves in Fig. 2.

The curves are equally applicable to circular pole-pieces, but are only approximately correct for rectangular ones with one side decidedly greater than the other.

The writer hopes to show the application of the above results to the calculation of the magnetic leakage in induction motors in a future article.

THE LATE MAJOR-GENERAL WEBBER.

We deeply regret to have to announce the death of Major-General C. E. Webber, C.B., R.E, who died on Friday last, having just completed his sixty-sixth year. The electrical engineering profession can ill afford to lose one by one the pioneers under whom so much progress has been made. Major-General Webber was in May of this year elected an honorary member of the Institution of Electrical Engineers. This election was a mark of the high appreciation in which the Council held the deceased member, and we hoped that he would be spared to enjoy the honour for many years. His sudden and, to us, unexpected death from angina pectoris ended an active and most useful life. For instance, it was only in our issue for Sept. 16 that we had a long letter from Major-General Webber on the organisation of the mechanical section of the British Association. We give elsewhere in this issue the list of the very numerous communications to the Institution of Electrical Engineers of which the late engineer was the author, and he contributed largely to the other learned societies also. When it is remembered that in practically every case he described for the benefit of the members and associates work actually carried out under his supervision, the extent of his experience as a pioneer in numerous branches of electrical engineers can be appreciated. When the first meeting of the Society of Telegraph Engineers was held in February, 1872, under the presidency of the late Sir William Siemens, Captain C. E. Webber, R.E, was already appointed a member of the council. Ten years later he reached the highest office in the then society—*i.e.*, that of president. A recent perusal of the presidential address delivered by Major Webber in January, 1882, affords a key to his whole professional life. In it he dealt with the true commercial principles underlying telegraphic advancement. He explained, for instance, that "the competition for efficiency in telegraph transmission is not international, as in the case of artillery, in which the work of one year's trial may have to be thrown aside and fresh expenditure undertaken because another nation has made an important advance. In telegraphs, what each country has to do is to keep up to the demands of its public life." He went on to describe the reason why the high cost of the typewriting telegraph instruments at that date prevented their general use as commercial instruments. He concluded that "technical societies are of more value in giving opinions on such points than international exhibitions." By the last expression was meant the judges' reports on international exhibits. Later on, in the same presidential address, the then Major Webber offered some virile criticisms of the defects in electric lighting as employed on her Majesty's warships, and gave practical advice as to the line in which improvements should be made. Speaking of the Society of Telegraph Engineers, which has since become known by the wider title of the Institution of Electrical Engineers, it was pointed out that liberal principles were the mainspring of such organisations. To quote Major-General Webber verbatim: "Whether in his desire to learn or to teach, each finds here a place where he can ventilate his ideas, so that he is often saved disappointment, annoyance, and expense by having them first subjected to the friendly criticisms of his fellow-members. In this lies the liberality of our society, that the platform of our qualification for membership and association is as wide as the field of application and use of electricity—a field which we are daily realising embraces all nature, on the margin of which our baby experiments have only as yet given us a foothold." The liberality so ably expounded in this address, delivered as long ago as 1882, has been the

Digitized by Google

keynote of Major-General Webber's professional life. He was always ready to place at the disposal of others his technical experience. This, quite apart from the large amount of pioneering work carried out by him in telegraphy, electric lighting, electro-chemistry, and telephony, renders his death most deeply felt by all who were honoured by his acquaintanceship. His friends have a still deeper cause for regret.

"THE TRUTH."

It may seem strange to anyone on their first visit to a court of law that the form in which the oath is administered does not stop at the first clause, which binds the witness to speak "the truth." Instead of this it goes on to say that he shall speak "the whole truth, and nothing but the truth." We would commend this common form of oath to our contemporary the *Journal of Gas Lighting*. In its last two issues it has had a good deal to say on the Wood Green case, which was commented on in our leading article of Sept. 16. One of our electrical contemporaries commenting on the same issue that week expressed opinions which are diametrically opposed to our own. We are more concerned, however, with our gas lighting contemporary, who for the past two weeks has committed itself to statements that only one electrical paper gave special attention to the matter, and that this paper applauded the action of the Local Government Board. In its last issue the editorial comments on Mr. Hawtayne are supposed to be exceedingly stringent, and criticisms are made as to his estimate of the probable number of the lamp connections in Wood Green. Mr. Hawtayne, in these estimates, is well within actual results obtained in similar places, of which Ilford is one, as we stated in our leading article Our contemporary, however, accuses him of selecting his comparisons unfairly. It says: "It would have been more to the point if Mr. Hawtayne had referred to Erith, although that is, according to those capable of making the comparison, a far more favourable district for electricity supply than Wood Green. There is also some appropriateness about Erith, because it happens to be one of Mr. Hawtayne's own progeny, and it ended its last financial year with a deficit of £781. But though the undertaking is not in a position yet to make the income cover the outgoings, the Council are now involved in more capital expenditure on extensions, which will mean a further addition to interest and sinking fund charges." There is nothing that is not true in this extract, but it is not the whole truth. Our contemporary hides up the fact that the last financial year at Erith, which ended with a deficit of £781, happened to be the first financial year of a young undertaking, and that the deficit, after paying capital charges, amounted to £1,801. 16s. 8d. If the undertaking were run by a company financed as most electrical companies in this country are, it could and would have paid a dividend of over 2 per cent. The fact that the Council are now extending is surely ample evidence that they have confidence both in Mr. Hawtayne and in the financial success of their electrical undertaking. We regret to see that the editor of our electrical contemporary adopts the same doubtful method of special pleading when referring to the Erith figures, and thus leaves the general reader to infer that this undertaking is an old-established and unsuccessful one. We would strongly recommend both our contemporaries in the future to remember the second clause in the form of oath referred to above, and that "the whole truth" is even more important than a part of it. We are sending a copy of this to the *Journal of Gas Lighting*, and shall be pleased to see what its editor has to say of the whole truth when it is forced on him.

OBITUARY.

Major-General Charles Edmund Webber, C.B., R.E. (retired), died at Margate on Friday last suddenly from angina pectoris. The funeral service was held at 10 a.m. on Wednesday last at the Brompton Parish Church, and was attended by a number of his professional friends. The Institution of Electrical Engineers was represented by Mr. Alexander Siemens, president-elect; Prof. W. E. Ayrton, F.R.S, Prof. Carey Foster, F.R.S., Dr. J. W. Swan, F.R.S., and Prof. S. P. Thompson, F.R.S., past-presidents; Dr. J. A. Fleming, F.R.S, Mr. J. E. Kingsbury, Mr. W. M. Mordey, and Mr. W. H. Patchell, vice-presidents; Mr. F. Gill and Mr. S. Morse, members of council; and by Mr. P. F. Rowell, assistant secretary. The following were also present at the interment at St. Margaret's, Lee: Mr. A. Siemens, Dr. J. W. Swan, Mr. W. M. Mordey, and Mr. P. F. Rowell.

THE LATE MAJOR-GENERAL WEBBER, PAST-PRESIDENT, INSTITUTION OF ELECTRICAL ENGINEERS.

Major-General Webber had just completed his sixty-sixth year, and was well known to electrical engineers in consequence of the large amount of electrical work for which he had been responsible. The following notes show that in military circles his experience was equally wide. Thus, during the suppression of the Indian Mutiny, he served with the 21st Company of the Royal Engineers throughout the Central Indian campaign in 1858 under Sir Hugh Rose (afterwards Lord Strathnairn, and was present at the siege and storming of Chandairie, and in charge of the only successful ladder party at the escalade of Jhansie, where he was one of the officers who led the assault. From 1870 till 1879 he commanded the Royal Engineers employed on postal telegraphs, and in May, 1879, accompanied Sir Garnet Wolseley to South Africa on special service, serving till the end of the war in Zululand and Natal as assistant-adjutant and quartermaster-general of the western lines of communication, and during the operations against

Digitized by Google

Sekukuni in the Transvaal, which again obtained for him mention in dispatches and a second medal with clasp. Becoming a lieutenant-colonel in January, 1880, he took part in the Egyptian war of 1882 as assistant-adjutant and quartermaster-general at headquarters, in charge of the telegraph lines, when he was present at the battle of Tel-el-Kebir, was mentioned in dispatches, and received the medal with clasp, the bronze star, the Companionship of the Bath, and the 3rd Class of the Medjidie. He also served in the Nile expedition of 1884-5, for which he was awarded a clasp to his Egyptian medal.

In electrical matters Major-General Webber took a most active part, as is evidenced by his association with the Institution of Electrical Engineers. He was one of the original members when the old Society of Telegraph Engineers was formed in 1872, and since then regularly contributed papers for discussion. The following list of these is worthy of careful study as showing the range of his practical work. We have added the date before each paper: Nov. 13, 1872, "On Military Telegraphs in Connection with the Autumn Manœuvres"; Feb. 12, 1873, "On the Application of Iron to Telegraph Poles"; Nov. 27, 1878, "On Multiple and other Telegraphs at the Paris Exhibition"; Jan. 10, 1882, Presidential Address; Nov. 23, 1882, "Notes on the Telegraphs used during the Egyptian Expedition of 1882"; Nov. 12, 1885, "The Telegraphs of the Nile Expedition"; June 22, 1891, "Electric Lighting from Central Stations, with special reference to the Chelsea System"; Feb. 8, 1894, "Some Notes on the Electric Lighting of the City of London"; Jan. 27, 1898, "Electrochemical Treatment of Ores containing the Precious Metals"; August, 1900, "Notes of Exhibits Illustrating Applications of Electricity in Paris Exhibition."

Besides these numerous papers, the deceased engineer regularly took part in the discussions on papers read by others, so that he will be greatly missed when the Institution meets this next month. He was always ready to co-operate in any step for the advancement of the industry of which as a pioneer he did so much to establish.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

COMMUTATION OF CONTINUOUS-CURRENT GENERATORS AND MOTORS.

SIR,—I see that in your issue of Sept. 23 you have printed copy of our paper on "Commutation of Continuous-Current Generators and Motors." This article has apparently been taken from uncorrected copy of the paper, a few of which copies accidently got into circulation. I, therefore, send you a list of corrections, which I should be glad if you would kindly print in your next issue:

Page 444, line 1: "leading pole-tip" should read "trailing pole-tip."

Page 445, second column, line 5: "cross over" should read "meet."

Page 446, line 8 of section headed "Reactance Voltage," "opposing" should read "assisting."

Page 446, line 10 of same section, should read: "Result of this induced E.M.F. will be to retard the rise or fall of the original current," instead of the reading given.

Page 446, lines 20 and 21 of same section, the formula of induction expressed in henries should read: "Lines surrounding one turn × total number of turns × 10^{-8} ÷ number of amperes."

Page 447, second column, third line from bottom: "Fig. 5" should read "Fig. 6."

Page 448, first column, fourteenth line: "Fig. 6" should read "Fig. 7."—Yours, etc., G. A. NEILD.

A SPORTING OFFER

SIR,—In your issue of 16th inst. you have reproduced a statement made by Mr. Hammond in his recent letter to the Municipal Council relative to an estimate of "total costs" which I prepared for the Lord Mayor in January, 1901, and as the comparison of 2½d. and 1½d. per unit is not accurate, I have felt it to be my duty to address a letter to the town clerk of Dublin setting forth textual extracts from my report of 1901, which speak for themselves. I may say, in passing, that while I did *not* include in my forecast of 1901 a "substantial sum" to cover the "vagaries of municipal administration in Dublin" or the "muddling" of either the then or present Electric Lighting Committees, I did include in my 2d. estimate such items as the cost of carboning and trimming 500 public arc lamps, etc., which must first be deducted from the 2d. referred to before any true comparison can be obtained between my estimate and Mr. Hammond's of 1·5d., which admittedly left out of account altogether one item at least—viz., £2,000 for carbons and trimming—£4 per arc lamp has to be paid by the Corporation, in addition to the £18 set forth in Mr. Hammond's scheme. If this one item alone of £2,000 be deducted, my forecast will stand at 1·81d.—Yours, etc.,

M. RUDDLE, City Electrical Engineer.

Electric Light Station, Dublin, Sept. 24, 1904.

SAND IN ENGINE BEARINGS.

SIR,—I should be glad to hear the name of any enamel suitable for the insides of enclosed engines—one which will fix any foundry sand, and will not be destroyed by either an oil and water bath, or by the oil used for forced lubrication.—Yours, etc., SANDY.

LETTERS FROM AN OLD HAND TO A YOUNG ONE.

IX.—ON SOFT SOAP.

MY DEAR YOUNG 'UN,—I must confess that the opening paragraph of your last letter "fetched" me. You refer to my letters in a really touching manner. You speak of their "racy" nature, "so different from the solemn platitudes that my pater sends"; you touch incidentally on their "sound common-sense," and you finally leave me an impression that, on the whole, you prefer me to all your natural relations put together, and that it is only want of spare cash that prevents you from giving me a substantial testimonial of your regard. Now, as I have somewhat the same opinions of my letters as those you mention, it naturally touched me to find in you such evidences of rare discrimination.

But the truth came home! When I was fairly in the ambush you opened out on me with "I know, by-the-bye, you have much influence with Messrs. ——. Could you manage to induce them to give me a berth?" . . .

Oh, my young friend, who taught you the use of soft soap? Of course I will write to Messrs. ——; not because you have flattered me, you understand, but because I have a very high opinion of your intelligence.

Soft soap is one of the most useful articles known to the engineer. When you want to draw in a cable through a pipe with a nasty bend, what do you use?—Soft soap. When you want to wash your hands at your employer's expense and can't find the oil barrel, what do you sneak?—Soft soap. And when you want to squeeze a job out of an innocent and unsuspecting small-scale potentate, what, again, do you employ?—Soft soap.

The art of ingratiation is almost as valuable to the engineer as the differential calculus. I don't care who the boss is; he may pride himself on being the infernallest martinet going, and may rap out his orders like a petulant Pom-pom, yet, other things being equal, he will be bound to give his mental preference to the assistant who is pleasant and civil over his work, rather than to the man who looks as melancholy as a washing-day, and jumps out his answers as if he grudges the carbon dioxide he uses on them. Only don't crawl. It is only the very worst kind of boss who is taken in by the Uriah Heeps who are externally beseeching him to place his foot on their necks.

When you go into the shops you will rub up against men who all want their own little bit of standing room—men with the funniest angles in their construction you ever dreamed of. Don't get trying to correct their faults and elevate their intelligences. You would need to be a combined hydraulic press and ten-ton crane to do that. Soft-

Digitized by Google

soap them. Humour their idiosyncrasies. If a man comes in to work on Monday morning with a head as big as a flywheel, nothing suits him better than to exchange some really acid remarks with the first fool who takes him seriously. Only, on Tuesday morning he forgets the head and remembers the remarks; and that's the way bad blood is made in the shops. Don't bring your slide-rule in your pocket in order to give the fitter at the next bench some Higher Education. The fitter will probably think you are merely monkeying, and the foreman will damn you for wasting time. What you want to do is, firstly, to make them think you allow that they may be better types of humanity than yourself, and, secondly, to make them tell you all they know in order to prove it.

If ever you are given charge of men, you will find a modicum of soft soap highly useful. If you have a hundred men under you, there will be fifty ways of getting the best work out of them. Your first object should be to lay down sound, inflexible by-laws to which you must bind yourself as strictly as every man under you. But closely following on this, you must grasp the peculiarities of temperament belonging to each man.

They all have their own opinion of themselves. If by working on that opinion you can get them to put forth their energies for you, you will be repaid for your soft-soap bill manifold. I knew a chief of a station who didn't have that idea. His notion of discipline was starvation wages and cat-o'-nine-tails. He had three shift engineers under him, and he made them slave—prided himself on being a holy terror to them—made a point of degrading them before the men they were paid to command. Well, they worried through the winter shifts, and kept the place going in good style. No thanks for that; when summer came he gave them extra jobs and extra bullying, because he knew that other stations were slack. But *that* wasn't the reason they were hanging on; they were waiting for the holidays. They worked extra shifts for each other till they had all had their fortnight, and then—one got another station job at twenty pounds less, another took up a sphere of usefulness in a manufacturing firm, and the third, who had money, flung up his job, and in doing so carefully explained to the chief what they all thought of him And that chief had to go through the next winter with three men who didn't know the details of the place any more than himself, and the amount of grovelling he did to his drivers and stokers was more than he would care to have mentioned. Give a man his place; make him have a suspicion that you respect his opinions. Humour his eccentricities if they don't interfere with discipline. In other words, apply soft soap.
